Incrustations in evaporators and other liquid heaters; Process of preventing gypseous ——. Aktieselskapet de Norske Saltverker. E.P. 131,279, 11.7.19. Conv., 14.8.18.

During the evaporation of sea-water and other saline solutions a small quantity of fine gypsum crystals is introduced into the liquor to form nuclei for the deposition of more gypsum, whereby, in conjunction with a sufficiently rapid motion of the liquor the gypseous deposits may be removed as mud instead of forming scale. If the liquor contains sulphates, such as magnesium sulphate, the primary addition may take the form of lime. —B. M. V.

Scale in boilers and evaporators; Process for removing calcareous ——. E. Möller. G.P. 326,019, 24.12.16.

A solution of kieserite and hydrochloric acid is introduced into the boiler whereby the calcium carbonate is converted into calcium sulphate and the resulting increase of volume causes softening and disintegration of the scale.—L. A. C.

Evaporator. F. W. Kreutter. U.S.P. 1,358,165, 9.11.20. Appl., 16.1.19.

An evaporator comprises a furnace with combustion chamber behind, and above these a front and a rear pan section, the front pan section having a rear wall inclined forwards and being connected at its rear end, by means of a pivoted conduit, with the front end of the rear pan section.—W. J. W.

Fractionating apparatus. Rosanoff Process Co., Assees. of M. A. Rosanoff and H. F. Perkins. E.P. 137,300, 29.12.19. Conv., 23.12.18.

An apparatus, specially suitable for carrying out the process described in E.P. 9654 of 1912 (F.P. 443,054; J., 1912, 102), comprises a number of nests of sloping tubes, each nest being maintained at a definite temperature (decreasing progressively in the direction of motion of the vapour) by means of an enclosing box through which cooling or heating fluid may be circulated. The vapour inlet being at the bottom and outlet at the top of the series of units, the condensed liquid from any unit will run back to the next hotter one by gravity.—B. M. V.

Distilling and heating apparatus. R. S. Mears. U.S.P. 1,358,091, 9.11.20. Appl., 2.1.19.

A boiler is provided with a condenser the two ends of which are connected with the steam and water spaces of the boiler respectively. A discharge pipe is connected with the pipe which connects the condenser with the water space of the boiler, and is provided with a check valve opening towards the boiler.—W. F. F.

Pulverulent materials; Apparatus for treating ——. A. P. E. Bourdet. E.P. 153,479, 16.12.19.

The material to be dried or otherwise treated is allowed to fall through a container across which are three sets of tubes. Two sets are perforated and serve for the supply and withdrawal of the treating fluid respectively, whilst the third set is non-perforated and serves for heating purposes.—B. M. V.

Surface apparatus for the transmission of heat. J. W. Mather. E.P. 153,509, 9.2.20.

In apparatus such as surface condensers the bank of tubes is made to taper so that a more or less sharp edge is presented to the incoming vapour or other fluid, and the cross-section available for passage of vapour is gradually reduced up to the point of maximum width of the outer casing, whilst the maximum depth of tube-bank comes opposite the middle of the inlet passage, where the velocity is highest.—B. M. V.

Furnaces; Gas fired ——. The Dowson and Mason Gas Plant Co., Ltd., and J. Paton. E.P. 153,511, 14.2.20.

The goods to be heated are passed, *e.g.*, on a moving hearth, through a long chamber, the middle portion of which is provided with burners coming up through the floor and the end portions of which are used for preheating and cooling the goods. The air for combustion enters flues in the walls of the furnace near the middle of their length, passes to the end and back again and then to a long passage across which jets of gas are blown in line with the burner holes in the hearth. The furnace is suitable for annealing tin plates.—B. M. V.

Precipitating suspended particles from gas; Apparatus for [electrically] ——. A. F. Meston, Assr. to Research Corp. U.S.P. 1,357,886, 2.11.20. Appl., 23.2.18.

The gas to be treated is subjected to the action of a transverse electric field in a flue comprising a perforated and a non-perforated section, and means are provided for intensifying the field adjacent to the perforated section.—J. S. G. T.

Gas purification [; Electrical——]. H. F. Smith, Assr. to The Smith Gas Engineering Co. U.S.P. (A, B, C) 1,358,030–2, 9.11.20. Appl., 4.8.17. (C) Renewed 4.8.20.

(A) Vapours are removed from gases by first removing the condensation nuclei and then condensing the vapours. (B) Gas is subjected to an electrical discharge and then passed through an electrostatic precipitating field. (C) A gas-purifying apparatus comprises a treatment chamber with inlet and outlet, an electrode between the two, and a second electrode between the first and the outlet. Means are provided for producing an electrical discharge adjacent to the first electrode and also by means of the second electrode to set up an electrostatic field of constant polarity.—C. I.

Gases; Apparatus for separating dust from ——. A. Möllinger. G.P. 324,413, 18.6.19.

The gas passes through a chamber containing groups of horizontal plates for collecting the dust, so arranged that, without interrupting the process, each group can be inclined temporarily to discharge the dust into a receptacle, whence it is removed as necessary.—L. A. C.

Agitating device. C. F. Woodhull. U.S.P. 1,358,045, 9.11.20. Appl., 13.2.20.

An annular mixing pan rotates and the material therein is stirred by fixed ploughs and discharged by scrapers through a central outlet which is opened when the inner cylindrical wall of the pan is lifted. Means may be provided for simultaneously lifting the wall and lowering the scrapers.—B. M. V.

Retort. P. Reecke. U.S.P. 1,358,327, 9.11.20. Appl., 17.10.17.

Material is fed into the upper end of an inclined retort arranged within and rotating with a concentric outer drum. The material is discharged at the lower end into a cooling receptacle without exposure to the air, and then passes into a water-jacketed receptacle provided with a stirring device. —W. F. F.

Filter, cleaner, or washer for air. J. Rudloff. U.S.P. 1,358,333, 9.11.20. Appl., 19.4.20.

AIR is drawn upwards through liquid contained in a vessel and then passes through a layer of filtering material, supported on a plate above the liquid. The density of the filtering material can be varied by means of a hand screw, acting upon a bowed elliptical spring, which presses a plate upon the filtering material.—W. F. F.

Drying process and apparatus therefor. C. Field, Assr. to Chemical Machinery Corp. U.S.P. 1,358,431, 9.11.20. Appl., 8.12.17.

A HORIZONTAL drying chamber suitable for drying plastic or semi-liquid compositions is provided with an end closure carrying a conveyor for the material within the chamber. The conveyor is bodily removed upon removal of the closure, and is automatically placed in or out of connexion with the driving means when inserted into or removed from the drying chamber.—W. F. F.

Drying tower. W. L. McLaughlin. U.S.P. 1,359,188, 16.11.20. Appl., 17.1.19. (*Cf.* U.S.P. 1,336,364 of 1920; J., 1920, 395 A.)

COMMINUTED material is supplied in a uniform sheet at the top of a tower by means of a spiral conveyor and a casing with a spiral edge, and falls through an upward stream of heated air, being deflected by staggered baffles on its way.—B. M. V.

Drying chamber. Internationale Ges. für Trockenanlagen m.b.H. G.P. 324,555, 22.7.15.

THE drying air enters the chamber in front at the bottom and passes out behind at the top. The material to be dried is placed on horizontal perforated partitions within the chamber.—L. A. C.

Crucible [; Double walled ——]. A. E. Bellis, Assr. to Collins and Roessel, Inc. U.S.P. 1,358,816, 16.11.20. Appl., 10.12.19.

A CRUCIBLE has an outer wall resistant to oxidising gases and a removable non-refractory lining resistant to chemical salts.—B. M. V.

Pulverising mill. J. W. Fuller. U.S.P. 1,358,837, 16.11.20. Appl., 27.8.17.

GRINDING is effected by freely moving balls running against a fixed ring. The mechanism which drives the balls is provided with scoops or other means to raise the ground material out of the grinding zone and with other scoops to discharge it.—B. M. V.

Thickening mixtures; Apparatus for continuously ——. A. L. Genter, Assr. to General Engineering Co. U.S.P. 1,359,162, 16.11.20. Appl., 30.4.19.

A TANK with an outlet at the bottom is provided with a number of internal filter elements through any number of which filtrate may be withdrawn, while others may be cleaned simultaneously and while still submerged.—B. M. V.

Filling material for reaction and absorption apparatus; Tubular ——. H. Frischer. G.P. 324,441, 22.12.18.

THE tubes are split and bent in a suitable shape so that they fit into one another and provide an increased reaction surface.—L. A. C.

Absorption, scrubbing, and reaction tower. H. Frischer. G.P. 324,921, 30.9.19.

THE bottom of the tower is divided into compartments, each of which receives the liquid trickling down a different section of the tower, and by measuring the volume of liquid discharged from each section it is possible to ascertain whether the liquid is passing uniformly down the tower. —L. A. C.

Sludges; Process for draining —— on a filter. T. Steen. G.P. 324,866, 21.10.16.

THE suction on the filter is regulated automatically according to the permeability of the sludge to air and water and the thickness of the layer on the filter.—E. H. R.

Furnaces; Mechanical feeding ——. G. Gröndal. U.S.P. 1,360,210, 23.11.20. Appl., 20.4.18.

SEE E.P. 115,639 of 1918; J., 1919, 78 A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coals; Certain chemical aspects of the South Wales —— and coal-field. S. R. Illingworth. Joint Meeting of Fuel Economy Committee of Brit. Assoc. and S. Wales Inst. of Eng., 26.8.20. [Advance copy.] 25 pp.

THE temperatures at which active decomposition commenced when typical South Wales coals were heated were found to increase with the increase of the carbon-hydrogen ratio in the coals. The behaviour of a coal below 500° C., it is suggested, determines its characteristic properties and economic uses. The different species of coal are differentiated by the amounts of pyridine-soluble constituents they contain, the thermal stability of these substances, their stability relative to one another, and their nature. From the results it is concluded that it should be possible to produce from highly bituminous coals any desired type of semi-bituminous, dry steam, or anthracite coal, by a process of fractional decomposition. It seems probable that Seyler's classification (Proc. S. Wales Inst. Eng., 21, No. 8 and 22, No. 3) based on the hydrogen content is on a true scientific basis, reflecting the chief substances determining the characteristics of a coal.—W. P.

Bituminous material; Distillation and gasification of ——. Bube. Braunkohle, 1920, **19**, 201—206. Chem. Zentr., 1920, **91**, IV., 611.

AN apparatus for the distillation of bituminous material designed to provide a graduated heating, to prevent local overheating, and to produce an increased yield of ammoniacal liquor, consists of a shaft furnace in which the material is heated to successively higher temperatures as it passes down over a series of horizontal partitions. A rotating arm attached to a central shaft sweeps over each partition and, after a complete revolution, the material falls on to the partition below. Air is introduced at the lowest partition, where the coke burns with the formation of carbon dioxide; on the partitions above the carbon dioxide is reduced to carbon monoxide; in the next higher zone, in which the gas is cooled by the addition of gas liquor vapour, distillation takes place; while in the uppermost zone the material is dried. Portions of the residue may be removed from any of the lower partitions, leaving only that necessary for combustion.—L. A. C.

Moist bituminous lignite; Rational utilisation of ——. T. Limberg. Braunkohle, 1920, **19**, 237—239. Chem. Zentr., 1920, **91**, IV., 611—612.

DISTILLATION of moist lignite in fireclay retorts or in gas producers is disadvantageous for several reasons, and the use of zone producers, such as those described in G.P. 302,322, 303,954, 313,470, and 322,646 (J., 1918, 331 A; 1919, 890 A; 1920, 441 A, 650 A), is recommended. The formation of pasty nuclear layers is thereby prevented, and no decomposition of the tar takes place, as it is diluted and removed from the apparatus at the time of formation.—L. A. C.

Ammonium sulphate; Direct recovery of ——. A. G. Cheal. S. Distr. Assoc. Gas Eng., Nov. 23, 1920. Gas J., 1920, **152**, 515.

FAILURES in the process for direct recovery of ammonium sulphate in gas works are often due to inadequate circulation of the liquor in the bubbler or the failure, with hot gas, to exclude tarry matter. The latter forms a scum on the surface of the liquor and both causes lead to loss of ammonia. In the discussion, P. Parrish pointed out that another source of loss is the carrying forward of a fine spray of weak acid solution from the bubbler into the oxide of iron purifiers, necessitating the occasional by-passing of the bubbler and the sacrifice of more ammonia to neutralise the iron oxide.—C. I.

Ammonium sulphate; Manufacture of neutral ——. E. V. Evans. S. Distr. Assoc. Gas Eng., Nov. 23, 1920. Gas J., 1920, **152**, 515—517.

THE process operated by the South Metropolitan Gas Co. consists in condensing the ammonia from the fixed ammonia still, and using the diluted solution to spray the crystals at 75° C. in a centrifuge; 8 galls. of solution containing 0·5% NH_3 suffices to neutralise 6 cwt. of acid salt containing 0·4% H_2SO_4. This is 40% of the quantity theoretically necessary, as washing proceeds along with neutralisation. Small quantities of ammonia escape during washing, and the evolution of pyridine necessitates the use of a draughting device. The salt containing 1—1·5% of water is dried by air heated to 150° C. in a tower, the descending salt being distributed by hollow perforated pyramids and staggered triangular bars and flaps. Several cycles are needed to bring the salt down to 0·04% of moisture.—C. I.

Gas; Calorific power and testing of ——. E. V. Evans. Southern Assoc. Gas Eng., Nov. 23, 1920. Gas J., 1920, **152**, 511.

A RECORDING calorimeter, known as the "Caloriscope," is described. It is a modification of Brady's apparatus (J., 1919, 938 A). Its principle depends upon the fact that when air is admitted in gradually increasing proportions to a luminous gas flame, or gas added to a non-luminous Bunsen flame, a point is reached when a luminous tip is just visible in the interior of the flame; the proportions of gas and air required to produce this effect afford a measure of the calorific value of the gas. A determination, accurate to within 1 or 2%, can be carried out in less than 30 seconds.—W. P.

Montan wax from a central German coal. R. Pschorr and J. K. Pfaff. Ber., 1920, **53**, 2147—2162.

CRUDE montan wax was crushed and extracted successively with ether and acetone; the extracts were separately hydrolysed with alcoholic potassium hydroxide, the potassium salts were converted into the calcium salts, and the latter exhaustively extracted with acetone. The mixture of alcohols and unsaponifiable matter thus obtained was acetylated, and the mixed acetates were separated from unsaponifiable matter by utilising their greater solubility in alcohol, and subsequently from one another by fractional crystallisation from ether-alcohol (1·1); tetracosanyl acetate, m.p. 59° C., ceryl acetate, m.p. 65° C., and myricyl acetate, m.p. 70° C. were thus isolated, from which the corresponding alcohols, m.p. 83° C., 79° C., and 88° C. respectively, were obtained. The ethereal extract yields mainly tetracosanol and ceryl alcohol, whilst the latter is obtained in an almost pure condition from the acetone extract. Isolation of montanic acid from the calcium salt (see above) is effected by treatment with benzene and hydrochloric acid, esterification of the crude acid with ethyl alcohol and sulphuric or hydrochloric acid, and hydrolysis of the purified ester, m.p. 66·5° C., in acid solution. Montanic acid, m.p. 83·5° C., is most readily isolated from the acetone extract. The ethereal extract contains 26% of free acid (reckoned as montanic acid), 41·8% of montanic ester, and 32·2% of substances of unknown composition; the corresponding figures for the acetone extract are 51·3%, 46·5%, and 2·2%, and for the residue, 0%, 63·5%, and 36·5%. The wax contains therefore 17% of montanic acid (as a maximum), 53% of montanic esters, and 30% of substances of unknown composition (as a minimum). (*Cf.* J.C.S., Jan., 1921.)—H. W.

Paraffin wax; Preparation of oxidation products of ——. A. Schaarschmidt and M. Thiele. Ber., 1920, **53**, 2128—2143.

CHLORINE was passed into melted paraffin wax at 160° C. in such a manner that the current of gas was finely divided by a Witt's stirrer; the gas was almost completely utilised, and the operation, which proceeded without the aid of external heat, was interrupted when the required gain in weight had been attained. Chlorination did not occur quite uniformly and, in addition to isomeric monochloro-derivatives, dichloro-products were also formed before all the paraffin was attacked. The chlorine was removed by heating the chloro-paraffins with alcoholic potassium hydroxide solution. By oxidation with potassium permanganate, an acid, $C_{14}H_{29}CO_2H$, was isolated (as silver salt) from an olefine which had the bromine value 20·4 and was obtained from a chloroparaffin with 10·6% Cl. The less saturated olefines absorbed oxygen far more rapidly and to a much greater extent. Since the oxidisability of these unsaturated hydrocarbons depends greatly on their state of division the following modifications of the procedure were adopted with an olefine obtained from a chloroparaffin with 32% Cl. The olefine was emulsified in an aqueous solution of sodium palmitate and treated with aqueous potassium permanganate; the latter was rapidly reduced, and reaction was practically complete when the weight of permanganate used was about six times that of the olefine. When the reaction was started with small quantities of sodium palmitate and olefine and further additions of the latter made in proportion as the potassium permanganate was reduced, the amount of crude acid formed was about the same, as was also the relative proportion of fatty acid and unsaponifiable matter, but the acid value of the products was greater than that of those prepared by the first method. When a considerable number of double bonds are present in the olefine, acids which are soluble in water are formed in notable amount, whilst much of the olefine is oxidised to carbon dioxide. Ozone is readily absorbed by the olefines at about 40° C. in the absence of solvent, the amount used corresponding approximately with the quantity of hydrogen chloride eliminated during the formation of the olefine. Fission of the ozonide may be effected with water and the non-acidic aldehydic portion subsequently oxidised with ozone; in this manner 105 g. of higher fatty acids and considerable amounts of lower acids soluble in water were obtained from 150 g. of olefine derived from a chloroparaffin with 19·4% Cl.—H. W.

Paraffin wax; Oxidation of —— to a true wax in ultra-violet light. A. Grün and T. Wirth. Z. angew. Chem., 1920, **33**, 291—292.

IN parallel experiments in which paraffin wax was oxidised for 3½ or 5 hrs. in a current of air at 160° C., ultra-violet light (U.S.P., 1,158,205; J., 1915, 1200) had hardly any influence upon the result. In fact the yield of alcohols and insoluble fatty acids produced was somewhat higher when the oxidation was effected in the absence of ultra-violet light.—C. A. M.

Aliphatic hydrocarbons; Oxidation of —— by nitrogen peroxide. C. Gränacher. Helv. Chim. Acta, 1920, 3, 721—737.

PARAFFIN-WAX, m.p. 50°—52° C., is oxidised by a current of air containing 2% of nitrogen peroxide to substances soluble in sodium hydroxide in 10, 7, 6, and 4 days respectively, at 110°, 120°, 135°, and 150° C. The products are not discoloured and consist of a mixture of acetic, butyric, and higher fatty acids, with about 15% of unsaponifiable oil. In order to determine the function and fate of the nitrogen peroxide, experiments with the pure gas were carried out at 140° C. Under these conditions, the gas is rapidly absorbed, more thorough oxidation is realised in 8—10 hrs., and the colourless gas evolved consists chiefly of nitric oxide. It would not be practicable to use nitrogen peroxide merely as an oxygen-carrier, however, for some nitrogen is lost as nitrogen gas, hydrogen cyanide, and, presumably, nitro-compounds, the alkaline solutions of the oxidised wax being red. When pure *n*-undecane is treated with nitrogen peroxide for 10 hrs. at 140° C., 40% of the hydrocarbon escapes oxidation and the products include no acid higher than nonoic acid besides the lower fatty acids. It follows that this method will not furnish any definite acid from a particular hydrocarbon. It is considered probable that the higher paraffins in nature only consist to a small extent of the normal members. (*Cf.* J.C.S., Jan.).—J. C. W.

Fermentation of cellulose. Fowler and Joshi. *See* XVIII.

PATENTS.

Fuel; Artificial ——. A. H. Ege. U.S.P. 1,357,627, 2.11.20. Appl., 12.5.19.

AN artificial fuel consists of powdered fuel and coke breeze bonded with a relatively small proportion of a binder composed of Portland cement, oxychloride cement, and salt. Petroleum is incorporated with the mixture, which is then caused to set hydraulically.

Coal carbonising furnaces. H. L. Doherty. E.P. 132,489, 10.5.19. Conv., 7.9.18.

COAL is fed into the top of a vertical retort and travels downwards against the upward flow of a burning mixture of gas and air. The rate of descent of the coal and the proportions of gas and air are so adjusted that a highly heated carbonising zone is maintained at the middle of the height of the retort, and this zone only is provided with a refractory lining. The lower end of the retort wall is perforated, and the charge is supported on an annular plate spaced downwards from the bottom of the wall, while a perforated cone is arranged above the central opening. The heating gas is admitted to the chamber surrounding the bottom of the retort so that it enters the fuel over substantially the whole area of the column. Oils and tar are collected in annular channels above the refractory lining, and gas is drawn off at the top of the retort.—W. F. F.

Discharging material [coke] at the base of shaft [coal carbonising] furnaces; Means for ——. H. L. Doherty. E.P. 152,965, 10.5.19. Conv., 7.9.18. (*Cf.* E.P. 132,489, *supra.*)

A FIXED annular shelf is supported under an annular opening at the bottom of the shaft. The opening is formed between the outer wall of the shaft and a fixed cone or other central obstruction. Mechanical means, such as a ring of a diameter rather smaller than the fixed annulus and which is given a gyratory motion, are provided to push the material over both the inner and outer edges of the shelf.—B. M. V.

Vertical retorts and coke-oven chambers; Method of sealing ——. F. J. Collin, A.-G. zur Verwertung von Brennstoffen und Metallen. E.P. 145,782, 2.7.20. Conv., 28.4.19.

A DISHED or cupped plate, into the cavity of which the bottom rim of the retort extends, is filled with granular coke kept moist by a small flow of water. The coke employed is that which, previously used for sealing the cover, falls into the dish when the cover is removed.—W. E. F. P.

Discharging vertical or inclined retorts or chambers; Means employed in ——. R. and J. Dempster, Ltd., H. S. Knight, and F. J. Siddall. E.P. 153,540, 6.7.20.

THE grate beneath the lower end of the retort consists of two pivoted sections of unequal length, one being a single arm and the other forming part of a rotary, multiple-armed device. The sections are controlled externally and can be operated independently or simultaneously.—W. E. F. P.

Wood gas producer. L. Avellana. E.P. 138,362, 28.1.20. Conv., 28.1.19.

A VERTICAL producer, in which combustion takes place in a downward direction, has a conical combustion chamber or shaft and a suspended grate, and is provided with means for the admission of air or the escape of gas through the side and between the grate bars. Beneath the grate is a chamber through which the gas produced passes into a second, lower chamber, communicating with the purifying plant.—W. E. F. P.

Gas-generating apparatus. H. J. Kotschevar. U.S.P. 1,357,998, 9.11.20.

OIL is discharged, through a jacketed delivery tube, into molten metal contained in a closed, heated retort. The discharge of oil is controlled by a valve actuated thermally, and varies with the temperature of the molten metal.—W. E. F. P.

Gas cooler. Façoneisen-Walzwerk L. Mannstaedt und Co., A.-G., and H. Bansen. E.P. 153,453, 16.10.19.

IN a gas cooler having vertical tubes which project into the gas chamber, the tubes depend from a distributor box to which the cooling medium is supplied, the seal between the box and gas chamber consisting of a curtain on the former which dips into a gutter around the jacket of the latter. The lower ends of the tubes are open and dip into a liquid seal by which the cooling medium, if liquid, is carried away. For use with a gaseous cooling medium the liquid seal is provided with a false bottom, from the gas space beneath which short tubes project through the sealing liquid into the cooling tubes; and apparatus for spraying the cooling tubes internally is arranged within the distributor box.—W. E. F. P.

Oil; Method of extracting —— from shale, coal, or other oil-bearing minerals. H. Edwards. E.P. 153,663, 9.8.19.

THE material is crushed and, after separation of the bulk of the pyrites by a metallurgical ore concentration process, is carbonised at about 500° C. in a muffle, *e.g.*, a muffled Merton furnace. Sulphur is completely removed from the oil thus obtained during the ordinary refining processes.—L. A. C.

Mineral oils; Process of purifying ——. J. Smith. E.P. 153,844, 14.4.20.

THE oil is heated under a pressure of 100—150 lb. per sq. in. in the presence of an absorbent such as cotton waste saturated with a strong solution of an alkali hydroxide, carbonate, or bicarbonate.
—L. A. C.

Mineral oils; Acid refining of ——. H. W. Hutton and F. J. Neilson. E.P. 153,857, 20.5.20.

Washing with alkali of a mineral oil which has received a heavy acid treatment is facilitated by the addition to the oil of sufficient sulphonated fatty oil, *e.g.*, sulphonated castor oil, to dissolve the sulpho acids from the oil, either before, during, or after the addition of the alkali.—L. A. C.

Fuel oil; Process for preparing a heavy ——. B. Szelinski. G.P. 299,683, 10.11.16.

A heavy fuel oil, lighter than water, from which solids do not separate during use, is prepared by mixing with petroleum products the coal-tar fraction (sp. gr. 1·05—1·07) boiling between 280° and 325° C.—E. H. R.

Gas-producers; Process for increasing the efficiency and the yield of ammonia in ——. H. Koppers, Assr. to The Koppers Co. U.S.P. 1,360,117, 23.11.20. Appl., 9.9.14.

See G.P. 279,550 of 1913; J., 1915, 414.

Hydrocarbons; Process of and apparatus for the alteration of high-boiling-point —— *to low-boiling-point hydrocarbons.* F. A. Kormann. E.P. 153,654, 6.8.19.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Carbonaceous materials; Apparatus for distilling ——. *Process for carbonising carbonaceous materials. Process for distilling carbonaceous material.* G. W. Wallace. U.S.P. (a) 1,358,662, (b) 1,358,663, and (c) 1,358,664, 9.11.20. Appl., 6.8.18, 23.1.19, 16.6.19.

(a) A vertical retort is provided with a central vertical discharge pipe for gases projecting upwards through the bottom nearly to the top and perforated throughout its length within the retort. The discharge pipe is provided with an annular flange near the bottom of the retort to support the charge and can be detached from the gas-exit main below, which is common to a number of retorts. A travelling crane is provided above the retorts by means of which the discharge pipe and flange carrying the residue of the charge can be withdrawn upwards through the retort. (b) In a retort similar to that described in (a) means are provided for automatically relieving pressure produced in the retort by gas evolved from the material outside the coking zone. (c) In a retort similar to that described in (a) the material in the coking zone is maintained in an "uninterrupted condition" by providing a number of spaced annular supports on the central discharge pipe.—W. F. F.

Incandescence gas mantles. H. Pace. E.P. 153,828, 8.3.20.

A fabric for the manufacture of incandescence gas mantles is composed of chrysotile and ramie thread or other material such as artificial silk. The ramie or other material is preferably shrunk as much as possible before weaving with the chrysotile.
—J. S. G. T.

Intense light; Production of ——. Siemens-Schuckertwerke G.m.b.H. G.P. 325,875, 6.4.18. Conv., 7.4.17.

A molten metal such as magnesium, aluminium, or zinc, or copper if a green light is desired, is atomised and burnt in an atmosphere containing a high percentage of oxygen.—L. A. C.

Röntgen tubes. Siemens und Halske A.-G. G.P. 325,941, 4.1.18.

The anticathode is formed of tungsten or molybdenum with a mirror of platinum, iridium, or an alloy of the two. These anticathodes are specially suitable for Röntgen tubes depending on pure electron discharges, working without special cooling and giving very hard rays in large quantities.
—E. H. R.

Wood preservation. G.P. 325,543. *See* IX.

Esters from pyroligneous acid. G.P. 325,639. *See* XX.

III.—TAR AND TAR PRODUCTS.

Patents.

Producer-gas tar; Removal of water from crude ——. O. Heise. G.P. 325,157, 7.10.17.

The tar is filtered hot, and, after it has cooled, is broken up, *e.g.*, by forcing through sieves, and is then passed in a fluid condition over sloping surfaces or rotating drums.—L. A. C.

Anthraquinone; Process for the purification of ——. Kinzlberger & Co. E.P. 143,885, 27.5.20. Conv., 20.9.17.

A solution of crude anthraquinone in a neutral solvent, such as chlorobenzene or solvent naphtha, is boiled and agitated in the presence of a purifying agent, such as an alkali or alkaline-earth oxide or carbonate, or an aqueous solution of the same, or dilute or concentrated sulphuric acid. When purification is complete, the anthraquinone solution is separated, and the solvent is removed by steam distillation.—L. A. C.

Anthracene; Process for the purification of crude ——. Kinzlberger & Co. E.P. 144,648, 7.6.20. Conv., 30.10.16.

Carbazole is separated from crude anthracene by agitating a boiling solution of the anthracene in solvent naphtha (b.p. 145° C.) with potassium hydroxide until water no longer distils over, further quantities of solvent naphtha being added if necessary. The solution is separated from the sandy precipitate of potassium-carbazole, and deposits pure anthracene on cooling.—L. A. C.

Pyridine bases; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 146,869, 5.7.20. Conv., 22.6.17.

Pyridine bases are obtained by heating paraldehyde with aqueous ammonia. It is advantageous to work under stoichiometric conditions and not raise the temperature above 200° C. For example, 132 pts. of paraldehyde when heated with 255 pts. of 5% aqueous ammonia in an autoclave for 4 hrs. at 140° C., 4 hrs. at 160° C., and finally 4 hrs. at 180° C., gives a mixture of pyridine bases consisting for the most part of 2-methyl-5-ethylpyridine, the yield amounting to about 68% of the theoretical.
—G. F. M.

Nitro compounds, nitroso and azo compounds, or the like; Reduction of substituted ——. T. S. Moore. U.S.P. 1,358,324, 9.11.20. Appl., 26.7.20.

AROMATIC nitro compounds containing at least one substituent other than a nitro group are rapidly reduced by means of borings of cast iron and an aqueous solution of a chloride.

Fuel oil. G.P. 299,683. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

Adsorption compounds [of dyestuffs]. III. R. Haller. Kolloid Zeits., 1920, 27, 30—34. (*Cf.* J., 1918, 411 A; 1919, 281 A.)

THE substrate in the complex Cotton Red 4 BX-lead hydroxide may be changed into lead sulphate, or lead sulphide, without setting free the dyestuff, but conversion into lead acetate, sodium plumbite, lead chloride, or lead chromate at once sets the dyestuff free. From these results two general rules may be deduced. When the substrate is converted into a soluble compound the adsorption complex is destroyed. When the substrate is converted into an insoluble compound which is capable of adsorbing the dyestuff, a new complex is formed without apparent dissociation of the primary complex, but if the insoluble compound has no adsorptive effect on the dyestuff the complex is destroyed and the dyestuff set free.—J. F. S.

Cyanines. Lumière and others. *See* XXI.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Cellulose; Constitution of ——. K. Hess. Helv. Chim. Acta, 1920, 3, 866—869. (*Cf.* J., 1920, 512 A.)

A REPLY to criticisms by Karrer (*cf.* J., 1920, 795 A). (*Cf.* J.C.S., Jan.)—J. C. W.

Fermentation of cellulose. Fowler and Joshi. *See* XVIII.

PATENTS.

Fibre, and process for obtaining the same [from seaweed]. Y. Hashimoto. E.P. 153,804, 13.1.20.

FIBRES suitable for paper making and as a cotton substitute are obtained from "sugamo" (*Phyllospadix scouleri*, Hook). The exterior of this seaweed is a gum-like material which cannot be separated by mechanical means, but is removed by boiling the raw or dried seaweed with milk of lime (10% CaO) for ½ to 1 hr. (aerial oxidation must be avoided), washing with water, boiling with a solution of sodium bisulphite of 1° B. (sp. gr. 1·007) for 20 to 50 mins., washing, and rubbing away the softened crust.—A. J. H.

[Vegetable] fibres; Method of treating ——. H. R. Moody and L. H. Friedburg. U.S.P. 1,357,580, 2.11.20. Appl., 13.1.17.

THE fibres of banana and other tropical plants are rendered suitable for the production of paper pulp or other purposes by immersion in sea water which is being electrolysed, whereby they are disintegrated and bleached.—A. J. H.

Wool or analogous materials; Process for removing fat from —— *by the aid of fat solvents.* F. Koch, Assr. to The Chemical Foundation, Inc. U.S.P. 1,358,163, 9.11.20. Appl., 3.2.14.

FAT or oil is extracted from wool or similar fibrous material by treating the latter with a chlorinated hydrocarbon of the fatty series, in absence of soap, soda, or other emulsifying agent.—W. J. W.

Fabric; Fireproof —— *and process of producing the same.* C. L. Saunders, G. C. Stanley, and C. W. Bennett. U.S.P. 1,358,250, 9.11.20. Appl., 13.10.19.

FABRICS are rendered fireproof by coating them with a composition containing ammonium sulphate and a hydrated oxide of tin. Cotton fibres are more easily impregnated with sodium stannate if they are first boiled in water, treated with a solution of commercial hydrofluoric acid (2 pts. of acid to 100 pts. of water), washed, and partially dried.
—A. J. H.

[Wood pulp] digesters. Aktiebolaget Vaporackumulator. E.P. 141,708, 12.4.20. Conv., 12.4.19.

THE pressure within a digester sometimes exceeds that of the steam supply, and acid is then forced from the digester into the connecting pipes. This disadvantage is overcome by the insertion of a pressure lock between the acid-proof valve nearest to the digester and the non-return valve nearest to the steam supply. The pressure lock consists of a piece of acid-proof tubing arranged vertically and is connected by means of a pipe, having an open valve, to a source of pressure of steam, water or air greater than the maximum attained in the digester. When the pressure within the digester temporarily rises above that of the steam supply, acid liquor flows through into the pressure lock and closes the non-return valve. The acid is thus prevented from entering the steam supply pipes, and rises in the pipe connected with the pressure lock until checked by the greater pressure therein. When the pressure within the digester becomes normal, the acid liquor is forced out of the pressure lock back to the digester, thus allowing the non-return valve to re-open.
—A. J. H.

Wood; Treatment of —— *and recovery of organic products therefrom.* H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,358,129, 9.11.20. Appl., 14.5.18.

WOOD of the western larch is comminuted and leached to extract the galactan and other soluble constituents, and the residue is subjected to chemical treatment for the preparation of pulp. The soluble matters are thus obtained uncontaminated with chemicals, and their removal reduces the consumption of chemicals in the subsequent treatment of the wood.—J. H. L.

Artificial threads, films and other products from viscose; Process for the manufacture of ——. R. Muller. E.P. 153,444, 9.10.19.

BY making the processes in the manufacture and use of viscose, cyclic, economy in the consumption of raw materials is possible. The caustic soda is prepared electrolytically from sodium chloride, and the gaseous by-products, hydrogen and chlorine, are suitably combined to form hydrochloric acid, which is used for precipitating the solution of viscose, whereby sodium chloride is formed and is recovered and used for the production of caustic soda.—A. J. H.

[Viscose;] Method and apparatus for the production of masses or solutions [of ——] free from air or other gases. B. Borzykowski. U.S.P. 1,357,946—7, 9.11.20. Appl., 13.8.17 and 6.4.20.

A FLUID mass of viscose or like material, suitable for the production of artificial threads, films, and the like, is "filmed" on a surface within a vessel exhausted of air. The mass is preferably incorporated with excess of an indifferent highly volatile solvent before treatment. The apparatus consists of a receptacle for containing the fluid mass, two chambers within which the mass is "filmed" under vacuum, and a filter between each chamber and the receptacle. A spinning system is connected with the two chambers and is exhausted of air.
—A. J. H.

Cellulose acetate; Composition of —— with the fatty acids of coconut oil. G. W. Miles, Assr. to American Cellulose and Chemical Manufacturing Co. U.S.P. 1,357,335, 2.11.20. Appl., 30.6.19.

CELLULOSE acetate is mixed with the total fatty acids extracted from coconut oil.—L. A. C.

Cellulose-ether composition and method of making the same. H. T. Clarke, Assr. to Eastman Kodak Co. U.S.P. 1,357,614, 2.11.20. Appl., 17.3.19.

A TRANSPARENT composition contains a cellulose ether and a sulphone.—L.A.C.

[Cellulose-ester films;] Purifying and washing process [for ——]. S. E. Sheppard, Assr. to Eastman Kodak Co. U.S.P. 1,357,733, 2.11.20. Appl., 5.6.18.

ACIDIC substances are removed from cellulose-ester bodies, having a large surface in proportion to their mass, by washing them with a strong solution of a salt.—A. J. H.

Nitrocellulose composition. J. M. Kessler, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,357,876, 2.11.20. Appl., 6.12.19.

NITROCELLULOSE is incorporated with an alkyl ester of an acyloxy derivative of a higher fatty acid.

Paper-making stock; Process and apparatus for preparing ——. C. H. Allen and E. J. Trimbey, Assrs. to Great Northern Paper Co. U.S.P. 1,357,760, 2.11.20. Appl., 21.8.19.

FLUID mixtures or solutions of the several ingredients of the stock are continuously poured into a common stream in the desired proportions.
—A. J. H.

Separating water or other liquids from solutions [cellulose waste lyes]; Method of ——. E. Oman. U.S.P. 1,359,911, 23.11.20. Appl., 18.9.17.

SEE G.P. 316,592 of 1917; J., 1920, 483 A.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

PATENTS.

Skein-dyeing machine. A. T. Scaramuzzi, Assr. to T. J. Corrigan. U.S.P. 1,357,522, 2.11.20. Appl., 4.9.19.

A DYEING machine contains a series of elongated horizontal skein carriers on a horizontal support. A carriage moves from one end of the support to the other, and is so constructed that each skein carrier is in turn displaced from the front to the rear of the advancing carriage.—A. J. H.

Dyeing machine. H. M. Dudley. U.S.P. 1,359,043, 16.11.20. Appl., 9.12.19.

THE dyeing machine consists of a receptacle divided into three parts. The middle division forms the dyeing chamber, which is closed at the top and bottom by perforated plates with covers, and contains several removable rods. The upper and lower divisions serve as liquid containers, and each contains a perforated pipe. Means are provided for circulating a liquid in either direction through the perforated pipes and the dyeing chamber.—A. J. H.

Cotton and cotton manufactures; Process of treating [fireproofing] ——. S. Kashitani. U.S.P. 1,360,224, 23.11.20. Appl., 10.12.18.

SEE E.P. 144,083 of 1919; J., 1920, 542 A.

Cleaning agent. E.P. 146,222. *See* XII.

Cleaning process. G.P. 325,796. *See* XII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Townsend [electrolytic] cell; Chemical efficiency and concentration of caustic soda and salt from ——. A. H. Hooker. Chem. and Met. Eng., 1920, 23, 961—968.

A DESCRIPTION of the plant at Niagara Falls, producing 65 tons of caustic soda and 60 tons of chlorine daily, is given. Types of cell in use are of 2500, 5000, and (most recent) 4000 amp. capacities. A high current density of 100 amp. per sq. ft. of cathode, at a little over 4 volts per cell, is used, with an average current efficiency of 96—97%. The caustic soda concentration is 125 g. per l. Curves showing various data in connection with the cell are given, including specific gravities of brine and caustic soda solutions, solubilities of chlorine in water and brine, chemical efficiencies, and evaporator data.—J. R. P.

Chlorate; Influence of chloride on the solubility of —— and its dependence on temperature. J. Billiter. Monatsh. Chem., 1920, **41**, 287—295.

THE solubility of sodium chlorate in unit volume of either water or sodium chloride solution increases linearly with the temperature, and the diminution produced in the solubility of sodium chlorate by addition of sodium chloride increases as the temperature rises, the extent of the increase being specially great for high concentrations of the chloride. (*Cf.* J.C.S., Jan., 1921.)—T. H. P.

Salts having a common ion; Separation of two ——. A. T. Schlœsing. Comptes rend., 1920, **171**, 977—981.

USING the pure salts, curves are first plotted showing the composition of solutions saturated with respect to the two salts at different temperatures. The solution from which it is required to separate one salt is analysed, and from the data obtained and the curves previously plotted it is possible to determine the temperature at which the solution should be evaporated, so that only one salt will separate out.—W. G.

Potassium iodide; Titration of —— with mercuric chloride. I. M. Kolthoff. Pharm. Weekblad, 1920, **57**, 836—842.

THE corrections which must be made in the titration are shown to be easily calculated by applying the laws of mass action to the balanced reaction, $HgI_4 \rightleftarrows HgI_2 + 2I$, the complex-constant for this dissociation, and the solubility of mercuric iodide being known. The correction as determined from theory is found to agree exactly with the figures obtained by the use of known solutions. Temperature has very little effect on the end point, and foreign substances interfere only in so far as they have a tendency to form complex mercuric salts. (*Cf.* J.C.S., Jan., 1921.)—S. I. L.

Mercuric chloride; Analysis of ——. I. M. Kolthoff and J. Keijzer. Pharm. Weekblad, 1920, **57**, 913—919.

RUPP's method of reduction by means of formalin in alkaline solution, and estimation of the separated mercury with iodine in acid solution, gives variable results, partly because reduction is incomplete, partly because formalin itself, after heating with alkalis, absorbs iodine in acid solution. Hydrogen peroxide is a more suitable reducing agent, but the method is in any case laborious. Rapid and accurate results may be obtained by adding to the mercuric chloride solution a slight excess of hydrocyanic acid and titrating the solution with caustic soda, using dimethyl-yellow as indicator. Care must be taken that both solutions are neutral to the indicator before mixing, and that

the hydrocyanic acid solution is free from cyanic acid. (*Cf.* J.C.S., Jan., 1921.)—S. I. L.

Dolomite; Experimental separation of lime in ——. R. T. Stull. U.S. Bureau of Mines. J. Franklin Inst., 1920, **190**, 739.

THE presence of lime in dolomite interferes with its use for the manufacture of fire-resistant brick. Treatment of a dolomite containing, after calcining, MgO 42%, CaO 58%, with running water for one day increases the magnesia content to 65% and allows a 50—60% recovery of lime. Boiling the calcined dolomite in water and separating the magnesium hydroxide by flotation gives 65—75% magnesia content, with 25% lime recovery. Addition to the calcined dolomite of sulphuric acid sufficient for all the lime, gives a 75% magnesia content with 50% lime recovery.—B. V. S.

Ozone; Action of —— *on alkali metals, ammonia, and substitution products of ammonia.* W. Strecker and H. Thienemann. Ber., 1920, **53**, 2096—2113.

WHEN ozone was passed into solutions of the alkali and alkaline-earth metals in liquid ammonia, orange to brown precipitates were obtained, which were very unstable, being rapidly decomposed by water or dilute acids with evolution of oxygen. On this account, and because the precipitates were contaminated with the oxidation products of ammonia, their composition could not be determined. Ozone oxidises liquid ammonia completely to ammonium nitrate (about 98%) and nitrite (about 2%), according to the equations $2NH_3+4O_3=NH_4NO_3+4O_2+H_2O$; $2NH_3+3O_3=NH_4NO_2+3O_2+H_2O$. The action is retarded but not stopped by drying the ozone as completely as possible. Hydroxylamine hydrate is oxidised by ozone to hydroxylamine nitrate, whilst hydrazine hydrate gives mainly nitrogen and water, with traces of nitrate and ammonia. Methylamine is oxidised to formaldehyde, ammonia, nitrate, and nitrite, and dimethylamine gives in addition formic and acetic acids. Trimethylamine is oxidised explosively even at very low temperatures. By passing ozone into a 5—10% solution of trimethylamine in chloroform, trimethylamine oxide, $(CH_3)_3N:O$, was obtained in the form of its hydrochloride. (*Cf.* J.C.S., Jan., 1921.)—E. H. R.

Chlorine and ammonia; Reaction between ——. *II.* W. A. Noyes and A. B. Haw. J. Amer. Chem. Soc., 1920, **42**, 2167—2173. (*Cf.* Noyes and Lyon, J., 1901, 943.)

ANHYDROUS ammonia and anhydrous chlorine react to form nitrogen trichloride and ammonium chloride: $4NH_3+3Cl_2=3NH_4Cl+NCl_3$. A considerable proportion of the trichloride always decomposes into chlorine and nitrogen, either directly or by interaction between the trichloride and ammonia. The ratio of the number of mols. of chlorine to the number of mols. of ammonia may be varied between wide limits without affecting appreciably the ratio (4:3) between the number of mols. of ammonia and the number of mols. of ammonium chloride. The chlorine reacts primarily with the ammonia, but only to a trifling extent, or not at all, with the solid ammonium chloride formed. The reaction was carried out with the dry substances without a solvent, and also in presence of carbon tetrachloride or pentane.—J. R. P.

Chlorine and ammonia; Reaction between ——. *III. Probable formation of trichloro-ammonium chloride.* W. A. Noyes. J. Amer. Chem. Soc., 1920, **42**, 2173—2179.

DRY hydrogen chloride converts nitrogen trichloride quantitatively into ammonium chloride. The reaction may occur either with a solution of the trichloride in carbon tetrachloride or without any solvent. As the decomposition cannot be a hydrolysis in the absence of water, it is probably not a hydrolysis in the presence of water. The action probably consists primarily in the formation of trichloro-ammonium chloride, NCl_3,HCl, followed by the loss of an atom of positive chlorine with an atom of negative chlorine. The formation of nitrogen trichloride by the action of chlorine on a solution of an ammonium salt appears to be the reverse of the above reaction. Ammonium sulphate is much more suitable than ammonium chloride for the preparation of nitrogen trichloride. Chloro-amine and dichloro-amine are formed as well as nitrogen trichloride by the action of chlorine on ammonium salts. Treatment of an ammonium salt with hypochlorous acid gives a trichloride pure and free from chloro-amines. Nitrogen trichloride may be separated from a solution in which it is prepared by passing a current of air through the solution, drying the air and vapour of trichloride by passing through concentrated sulphuric acid, and condensing the trichloride in a U-tube surrounded by a freezing mixture.—J. R. P.

Arsenic; Pure metallic ——. C. H. Jones. Chem. and Met. Eng., 1920, **23**, 957—960.

ARSENIC of 99·5—99·7% purity is prepared by heating a mixture of 1 pt. of wood charcoal with 4 pts. of arsenious oxide in gas-fired furnaces holding 200 or 400 lb. of mixture. The furnaces are built up of steel pipe surrounded by firebrick, supported on pipe framework. The cover of the charging end is clamped against a clay gasket with a cooling pipe embedded, which condenses any leak of arsenic and forms a joint. The operation is carried out at a temperature of 650°—700° C., and takes 10 hrs. for the large furnace and 7 hrs. for the small. The chief impurity in the product is arsenious oxide. The arsenic is condensed in a water-cooled condenser at the rear of the furnace. The product has sp. gr. 5·73, is brittle, and may be powdered without difficulty. Among the uses mentioned are as a flux, for addition to copper, bronze, Muntz metal, arsenical lead, and speculum metal.—J. R. P.

Ammonium sulphate recovery. Cheal. *See* IIA.

Neutral ammonium sulphate. Evans. *See* IIA.

Transformation of ammonia into urea. Matignon and Fréjacques. *See* XX.

PATENTS.

Aluminium oxide; Producing —— *from aluminium chloride.* S. E. Sieurin. E.P. 153,500, 19.1.20.

RAW material containing aluminium is dissolved in hydrochloric acid and the solution saturated with hydrochloric acid gas, the aluminium chloride which separates being subsequently calcined. To obtain a strong gas suitable for saturating the solution only that evolved at the end of the calcination is taken (a furnace with several beds being used), or the surplus water is separated from the gas by condensation.—C. I.

Nitrate of soda; Recovery of —— *from solutions.* I. B. Hobsbawn. In part from J. L. Grigioni. E.P. 153,649, 6.8.19.

A MORE complete separation than hitherto of sodium nitrate from the chloride and sulphate accompanying it is effected as follows. The solution is boiled at 90°—95° C. under an absolute pressure of 11 lb. per sq. in., whereby much of the sulphate and chloride is precipitated. This stage is carried on as a continuous process. The settled liquor is drawn off and further concentrated at atmospheric pressure until the dissolved chloride is equivalent to 75—80 g. NaCl per l. The liquor is then cooled under slightly reduced pressure and crystallised in a rotary cooler.—C. I.

Potassium and sodium nitrates; Process of separating ——. R. P. Calvert, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,356,806, 26.10.20. Appl., 1.8.17.

Sodium nitrate mother liquors containing potassium nitrate in quantity equal to at least 20% of the mixed nitrates are subjected to a temperature of 5° C., and the potassium nitrate which separates from the solution is recrystallised.—W. J. W.

Nitrates and chlorides; Process of leaching and obtaining ——. W. E. Giesecke, Assr. to Ray Bros.' Corp. U.S.P. 1,357,973, 9.11.20. Appl., 27.3.17.

The raw material is mixed with a lixiviating agent, and its disintegration is assisted by blowing a fluid through it under pressure. The finest particles are thus forced above the heavier solids, and the settled material serves as a filter through which the solution is drawn off. Fresh lixiviating agent is then forced through the material from below together with air, and the solution is again filtered and removed.—W. J. W.

Potassium chloride; Preparation of —— *from crude, low-grade potassium salts.* Salzwerk Heilbronn, G. Kassel, and T. Lichtenberger. G.P. 325,398, 8.10.18. Addn. to 289,746 (J., 1920, 405 A).

The melt containing potassium chloride (*loc. cit.*) is heated until the latter is volatilised; it is purified by fractional condensation. If the potassium salts do not already contain chloride, salt or hydrochloric acid is added before heating.—E. H. R.

Gases; Removal of sulphur [hydrogen sulphide] from ——. N. E. Rambush. E.P. 153,665, 11.8.19.

The gas is washed with a suspension of ferric hydroxide in ferrous sulphate solution. The suspension circulates between the washer and a tower down which it flows against a current of air; or it may be simply run over a system of wooden lattice boards like a water cooler. A portion of the revivified suspension is drawn off and the sulphur separated by fractional subsidence or centrifuging. —C. I.

Arsenical salts; Method of making ——. W. Thum, J. J. Mulligan, and H. M. Schleicher, Assrs. to United States Smelting, Refining, and Mining Co. U.S.P. 1,356,569, 26.10.20. Appl., 28.6.19.

Insoluble metallic sulphates are treated with soluble arsenical salts to produce arsenical salts of the metals.—W. J. W.

Magnesium sulphate; Method of making ——. W. R. Collings and J. A. Gann, Assrs. to The Dow Chemical Co. U.S.P. 1,356,907, 26.10.20. Appl., 10.2.19.

Magnesium hydroxide is treated with sulphur dioxide, and the bisulphite formed is oxidised to sulphate.—W. J. W.

Magnesium carbonate or Magnesia usta; Manufacture of ——. W. Esch. G.P. 325,141, 13.10.14.

Calcined magnesia made to a paste with the requisite amount of water is converted into magnesium carbonate by the action of 1 mol. of carbon dioxide and 1½ mols. of ammonia (or, in the case of *Magnesia alba* which is dense or contains chlorides, of ½ mol. of carbon dioxide and ¾ mol. of ammonia), and is either separated or worked up to light *Magnesia alba* or *Magnesia usta*.—L. A. C.

Alkali-metal cyanide; Apparatus for manufacture of ——. F. J. Metzger, Assr. to Air Reduction Co. U.S.P. 1,358,014, 9.11.20. Appl., 5.12.18.

An inclined tubular retort has its middle portion enclosed in a furnace. The charge of an alkali and a carbonaceous material is fed in at the top and nitrogen passed in at the bottom, and by rotating the retort on its axis the lower portion, projecting beyond the furnace, serves as a cooling and nodulising zone for the reaction product.—C. I.

Alkali cyanide; Apparatus for manufacturing ——. F. J. Metzger, Assr. to Air Reduction Co. U.S.P. 1,358,383, 9.11.20. Appl., 25.7.17.

A retort of readily oxidisable metal is surrounded by a chamber of material resistant to oxidation, the intervening space being filled with inert gas. Heat is applied to the outer chamber.—C. I.

Metal [vessels] heated to a high temperature [e.g. in production of cyanides]; Method for protecting —— *against oxidation.* H. B. Kipper. U.S.P. 1,358,161, 9.11.20. Appl., 19.5.19.

Metal vessels heated to a high temperature, as in the production of nitrogen compounds by heating sodium salts with carbon and iron in presence of nitrogen, may be protected against oxidation by burning carbonaceous fuel to carbon monoxide with a minimum of carbon dioxide, and by avoiding excess of oxygen.—W. J. W.

Cyanide compound and process of producing the same. W. S. Landis, Assr. to American Cyanamid Co. U.S.P. 1,359,257, 16.11.20. Appl., 16.1.20.

A mixture of crude calcium cyanamide, an alkaline-earth carbide, and a flux containing less sodium chloride than the molecular equivalent of the cyanide to be formed is heated and then immediately cooled below 400° C. The compound obtained contains a large percentage of calcium cyanide mixed with calcium oxide and fluxing materials.—C. I.

Sulphur dioxide; Process of reducing ——. T. Shiomi, Assr. to Furukawa Gomei Kaisha. U.S.P. 1,359,114, 16.11.20. Appl., 15.1.19.

Sulphur dioxide mixed with steam and a reducing gas is passed through a heated chamber filled with a catalyst.—C. I.

Phosphoric acid and compounds of the same; Process of and apparatus for producing ——. F. S. Washburn, Assr. to American Cyanamid Co. U.S.P. 1,359,211, 16.11.20. Appl., 21.4.19.

A mixture of phosphate rock and silicious material is preheated in a rotary furnace and then fused in two stages in a hearth furnace. The gaseous products of the last stage are used in preheating fresh charges.—C. I.

Hydrogen peroxide solutions; Stabilising ——. M. Sarason. G.P. 325,861, 3.7.18.

The addition of 0·2% of a hypophosphite—*e.g.*, sodium hypophosphite—to hydrogen peroxide or solutions of the same prepared from sodium peroxide or perborate prevents decomposition even if the solution is alkaline and maintained at 70° C. —L. A. C.

Hydrogen sulphide; Separation and recovery of sulphur from solutions, gases, and vapours containing ——. Gewerkschaft des Steinkohlen-Bergwerks "Lothringen," and G. Wiegand. G.P. 326,159, 13.12.18.

Vapours containing hydrogen sulphide are led, mixed with oxygen, over a solid contact mass sprinkled with a solution of ammonia, alkali, or alkaline-earth, the quantity of oxygen being regulated so that alkali polysulphides are formed, but no free sulphur. As catalysts, oxides and hydroxides of iron, manganese, aluminium, and related metals, or mixtures of these, may be used. The

polysulphides can be decomposed into sulphur and hydrogen sulphide and the latter again put through the process.—E. H. R.

Alkali amides; Process for the manufacture of ——. O. Liebknecht, Assr. to The Roessler and Hasslacher Chemical Co. U.S.P. 1,359,080, 16.11.20. Appl., 29.1.15.

SEE E.P. 1613 of 1915; J., 1915, 1143.

Magnesium chloride or anhydrous double chlorides of magnesium; Production of anhydrous ——. E. A. Ashcroft. U.S.P. 1,359,652, 23.11.20. Appl., 12.8.19. Renewed 9.10.20.

SEE E.P. 152,401 of 1919; J., 1920, 783 A.

VIII.—GLASS; CERAMICS.

Optical glasses; Relations between chemical composition and refractivity in ——. F. E. Wright. J. Amer. Ceram. Soc., 1920, 3, 783—832.

WHEN the mean optical dispersions and refractive indices of a series of ordinary crown and flint glasses are plotted as ordinates and abscissæ, the resulting graph is practically a straight line. When the refractive index and the ratio of the length of the red to that of the blue end of the spectrum are similarly plotted a smooth curve is formed. In fluor-crown glasses the length of the red end of the spectrum exceeds that of the blue end relatively more than in any other glass types; the borosilicate crowns follow next, then the ordinary crowns, barium crowns, and barium flints, and lastly the flints in which the relative dispersion of the blue exceeds that of the red end of the spectrum. From such a graph in combination with a table of analyses the chemical composition of glasses relative to their refringence and relative dispersions can be found. On plotting against one another the partial dispersions for different parts of the spectrum of a series of silicate glasses the resulting graph is a straight line, showing that each partial depression of a glass bears a linear relation to any other, so that if one partial dispersion is given, the type of optical glass is fixed, whilst if any two refractive indices of an optical glass are given the dispersion curve can be written down directly, and if two optical glasses of very different indices have the same dispersion for one part of the spectrum their dispersion curves are identical throughout the visible spectrum. These linear relations only hold for that portion of the dispersion curve remote from an absorption band. When the refractive indices are plotted against the squares of the frequency ($1/\lambda^2$) another straight line graph is obtained. With the rise in refractive index the dispersion also rises, the latter rising very rapidly in flint glasses. The chemical compositions of 117 potash-flint, soda-flint, barium-flint, borosilicate flint, barium crown, and borosilicate crown glasses from various sources, when arranged on a triaxial diagram, were found to lie on a straight line uniting the points representing the formulæ PbO,SiO_2 and $K_2O,6SiO_2$, or the corresponding soda glass $Na_2O,4SiO_2$. The whole of these glasses are analogous to two-component mixtures, and, as such, any one of their physical constants such as refractive index or density varies continuously with a change in composition. In preparing a batch to reproduce glass of given optical properties due allowance must be made for loss by selective volatilisation, suitable allowances being 0·5—5% PbO, 1—5% B_2O_3, and 0—5% of alkalis. By means of the foregoing data charts may be prepared from which the batch composition for a glass of any required density, refractive index, and dispersion can be read off directly. Examples of various batches prepared in this manner are given.—A. B. S.

Porcelain moulded under different conditions; Rate of vitrification of ——. R. F. Sherwood. J. Amer. Ceram. Soc., 1920, 3, 837—841.

TEST-PIECES of a typical porcelain body were made by hand-pressing of the plastic mixture in a plaster mould, by casting in a similar mould, and by dry pressing in a steel mould in an Olsen testing machine using pressures of 2000, 4000, and 6000 lb. per sq. in. respectively. The densest product was that formed by dry pressing at 6000 lb. per sq. in., and the least dense material was formed by hand-pressing of the plastic mixture. After firing at 1120° C. the initial porosity was lowest in the cast pieces, and greatest in the pieces dry-pressed at 2000 lb. per sq. in. The rate of vitrification was greatest in the plastic-moulded test-piece, this being followed by the cast material. There appeared to be a distinct difference in heat effect between wet-moulded and dry-pressed material. The cast body reached a given degree of porosity (not too far removed from complete vitrification) at the lowest temperature, and the dry-pressed material at higher temperatures, according to the pressure applied. Minimum porosity was reached simultaneously in all cases except by the pieces pressed at 2000 lb. per sq. in., which showed a slight lag. Complete vitrification was not reached at 1325° C. by the plastic-moulded sample or the one dry-pressed at 2000 lb. per sq. in. The relative compactness of a porcelain body appears to govern the temperature at which complete vitrification takes place and the time during which a given temperature must be maintained.—A. B. S.

Testing furnace [for ceramic products]; Construction of a novel ——. S. F. Walton. J. Amer. Ceram. Soc., 1920, 3, 833—836.

A SIMPLE form of gas-fired furnace for use in testing the modulus of rupture of refractory materials at high temperatures consists of a square base with well-hole and main flue, surmounted by a cylindrical wall built of carborundum bricks backed by 1½ in. of rammed kieselguhr and 4½ in. of fireclay bricks. The gas-ports were of galvanised iron, surrounded by fireclay and set tangential to the wall. The main flue was made by placing a 5-in. galvanised iron pipe inside a 7-in. iron pipe and filling the annular space with refractory cement. As the metal burned away it left the refractory material firm. For making the cross-breaking tests a lever arrangement is used, one end of the lever pressing through a knife edge of refractory material on the test-piece, which rests on knife-edges embedded in the floor of the furnace. The other end of the lever is connected with a chain jack, having a handle fitted to the sprocket wheel and set on a platform scale. A bucket hung from the balance arm of the scale is loaded by water from a Marriotte bottle.

Bores in glass; Production of ——. J. Kent. E.P. 153,824, 28.2.20.

GLASS tubing having more than one bore is made by forming an approximately cylindrical ball of glass on a single blowing-iron. A sealed length of exhausted glass tubing extending the length of the ball is autogenously united with it and the piece thus constituted is brought to the desired cross-sectional shape and drawn out to the required dimensions. By bedding-down a length of glass rod of lenticular cross-section upon the surface of the piece immediately over the small diameter bore and drawing out, a lens-fronted cylindrical bore thermometer tube with a capillary bore in the thickness of its wall is obtained.—H. S. H.

Flake materials [*mica*]; *Manufacture of sheets by aggregation of* ——. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 153,612, 25.2.18.

FLAKES (*e.g.* of mica) are deposited by a current of air upon a perforated endless belt travelling upon a horizontal rotating openwork cylinder within which suction is created. The distribution of flakes is rendered more uniform by obstructing the air current by a subsidiary screen. The air-current first strikes the fresh portion of the travelling screen and there deposits the larger flakes. The swirl of left-over flakes remains sufficiently long in contact with the screen and the initially formed layer to cover the small openings in the layer with flakes. The layer is carried round until it becomes horizontal, then receives adhesive and is manifolded.—H. S. H.

Clay; Treatment of ——. P. Schidrowitz, W. Feldenheimer, and W. W. Plowman. E.P. 153,861, 2.6.19.

CLAY, preferably purified, is suspended in water by means of a deflocculator (*e.g.* sodium carbonate), and before any settlement of clay substance takes place the whole clay suspension is evaporated to dryness. The suspension is made either by mixing the clay with sufficient water to produce a pasty mass and adding the deflocculator in the required quantity to obtain fluidity, or by directly working up the clay with water and the deflocculator together. Clay dried in a deflocculated state possesses qualities which are not obtainable when the drying is effected immediately after flocculation, and is suitable, for example, for incorporating in rubber mixings (*cf.* E.P. 153,343; page 19 A).
—H. S. H.

Abrasive block. F. P. Jones and A. Fleming. E.P. 153,692, 18.8.19.

SILICA sand, firestone, glass, or china (76 pts. by weight), magnesia (7), magnesium chloride (7), wax, sawdust, sulphur, or ammonium chloride (10), and water (10) are mixed together and moulded into blocks. When set the material is heated until the wax or its substitute is removed, the porosity of the block depending on the amount of wax or the like used.—H. S. H.

Furnace for melting glass and other purposes. J. S. Shaw. U.S.P. 1,359,756, 23.11.20. Appl., 4.5.20.

IX.—BUILDING MATERIALS.

Portland cement; Analysis of ——. F. Ferrari. Giorn. Chim. Ind. Appl., 1920, 2, 434—437.

A RAPID and exact method is described by which the following three groups of determinations are carried out simultaneously: (1) moisture; (2) loss on calcination, silicic acid, alumina, lime, and magnesia; (3) insoluble silicious residue, ferric oxide, and sulphuric acid. The method used for the rapid estimation of the silicic acid is based on the practically complete insolubility of gelatinous silica with a low water-content, and the iron is estimated by means of nitrosophenylhydroxylamine-ammonium (cupferron). The procedure to be followed is described in detail. The method is applicable to the analysis of limestone, unburnt cement, clays, etc., if these are subjected to preliminary scorification at about 1400° C.—T. H. P.

Iron-Portland cement and puzzuolana; Mixtures of ——. F. Ferrari. Giorn. Chim. Ind. Appl., 1920, 2, 549—554. (*Cf.* J., 1920, 821 A).

CEMENTS composed of mixtures of normal Portland cement and puzzuolana, although when set offering a much greater resistance than pure Portland cement to the action of sulphates and chlorides, eventually undergo slow disintegration, like all mixtures containing strongly basic aluminates. Normal mixtures with a base of iron Portland cement undergo retrogradation after a long period owing to the diffusion of the lime, whereas mixtures of iron Portland cement and puzzuolana are quite stable and practically impermeable and are suitable for use in contact with sea-water or water containing sulphates.—C. A. M.

Plaster; Dispersoid and colloid chemistry of ——. Wo. Ostwald and P. Wolski. Kolloid Zeits., 1920, 27, 78—92.

THE rate of setting of plaster and the processes occurring therein have been investigated by a study of the change in the viscosity of 3—5% suspensions of burnt gypsum. Such suspensions show an increase in viscosity for the first half-hour after preparation. The time-viscosity curves are S-shaped. The concentration of plaster has a marked influence on the setting, since the difference between the initial and final viscosities (hydraulic effect) increases extraordinarily rapidly with the concentration. No setting takes place at 60° C. and very little at 37° C., but at 0° C. the increase in viscosity, that is the setting, is very great. Freshly ground preparations show a greater hydraulic effect than aged specimens. The more finely divided the plaster the greater the hydraulic effect. The addition of potassium chloride up to 0·2*N* accelerates the setting of plaster, but eventually gives a smaller hydraulic effect than pure water. Concentrated solutions of potassium chloride retard the setting. Acetic acid, 2*N*, retards the setting but gives a somewhat larger hydraulic effect. Gelatin, 0·2%, and alcohol, 20%, completely inhibit the setting.—J. F. S.

Wooden poles and sleepers; Zinc fluoride as a preservative for ——. R. Nowotny. Oesterr. Chem.-Zeit., 1920, 23, 136—138.

TESTS on 15,763 telegraph poles extending over eight years show that zinc fluoride is a particularly suitable preservative, as it is soluble with difficulty and highly toxic to mould growths. The wood is soaked in a mixture of zinc chloride and sodium fluoride solutions, each of 1·75% concentration, and then heated to 45°—60° C. to form zinc fluoride or the basic fluoride. The total wastage of poles in eight years was only 6% (the loss for any one year never exceeding 1·82%), as compared with a total of 34% in the case of similar poles treated with copper sulphate. The best results are obtained when the timber absorbs about 3 kg. of zinc fluoride per cb. m. The chief drawbacks to the use of zinc fluoride are the inconvenience of liquid zinc chloride in transport and the premature formation of the fluoride. The latter may be prevented by neutralising the sodium fluoride solution by adding sulphuric acid or sodium bisulphate to it (the mixture must not react acid to methyl orange) prior to adding it to the zinc chloride. The use of zinc sulphate instead of zinc chloride (Renfer & Co. A.-G., Swiss Pat. 75,478 of 1917) is preferable. A satisfactory preservative may also be made by mixing powdered zinc sulphate, sodium sulphate, and sodium bisulphate in suitable proportions and dissolving the mixture in water when required for use. The timber should be thoroughly dried prior to impregnation.—A. B. S.

PATENTS.

Rotary kiln. A. Larsen, Assr. to F. L. Smidth & Co. U.S.P. (A—C) 1,358,759–61, 16.11.20. Appl., 12.5.20.

(A) A ROTARY kiln is divided into upper and lower kiln portions by a chamber communicating with

both portions and containing a partition wall with damper between the ends of the two portions of the kiln, so that products of combustion from one side of the partition can be directed to a heating chamber and thence to the other side of the partition. Means are provided to convey material from the upper portion of the kiln to the lower. (B) A rotary kiln comprises a continuous rotary shell with an opening through it and a casing surrounding the shell in line with the opening. Means are provided for conducting the products of combustion delivered to the casing through the opening in the shell to a heating chamber. Raw material is conducted within the shell from a point above the opening through the shell to a point below the opening. (C) A primary rotary kiln adapted to receive an excess of slurry in its evaporating and drying zone is provided between the evaporating and heating zone and the zone in which carbon dioxide is driven off, with an opening through which the excess of dried raw meal may escape and be transferred to a secondary sintering kiln.—H. S. H.

Concrete structures; Building material for ——. F. L. Smidth & Co. E.P. 137,330, 2.1.20. Conv., 1.5.18.

GROUND "moler" (diatomaceous earth) is heated until sintering starts (about 1100° C.) and mixed with Portland cement. The resulting concrete possesses greater elasticity and is a better insulator against heat and sound than concrete prepared with sand or gravel.—H. S. H.

Impregnating wood to preserve it; Process for ——. Grubenholz - Imprägnierung G.m.b.H. E.P. 141,728, 14.4.20. Conv., 29.11.13.

THE addition of an alkali chromate, bichromate, bromate, io-date, or chlorate, borax, or a dialkali phosphate, or a mixture of the same, to a solution of dinitrophenol or its salts for impregnating wood prevents decomposition of the solution when in contact with iron, and thus permits the impregnation to be carried out in iron vessels.—L. A. C.

Wood; Preservation of ——. Deuts. Erdöl-A.-G., and F. Seidenschnur. G.P. 325,543, 9.8.17.

WASTE material obtained from the wood, such as bark, sawdust, etc., is distilled, the waste heat from the retorts is employed for drying the wood, and the products of the distillation are used as a preservative.—L. A. C.

Wood; Process of and means for effecting colour transformation or change in —— and apparatus therefor. F. E. Williams. E.P. 153,619, 12.6.19.

WOOD is immersed in a boiling aqueous solution of copper sulphate and ferrous sulphate in substantially equal proportions.—H. S. H.

Sound-absorbing material for walls and ceilings. W. C. Sabine (J. D. K. Sabine, extrix.) and R. Gutavino. Reissue 14,992, 23.11.20, of U.S.P. 1,197,956, 12.9.16. Appl., 24.7.18.

SEE E.P. 110,194 of 1916; J., 1917, 1237.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron in basic open hearth [steel] practice; Use of high-manganese ——. E. A. Wheaton. Amer. Iron and Steel Inst., Oct., 1920. Blast Furnace and Steel Plant, 1920, 8, 596—598.

PIG iron containing 1·39—2·13% Mn manufactured in the blast furnace with lean slags and having a sulphur content as high as 0·1% was delivered to the open-hearth furnace through a mixer with a 50% elimination of the sulphur. This iron improved the quality of the steel, the manganese diminishing the sulphur in the charge and eliminating the oxygen. The tonnage was maintained, and the average time of heats showed a considerable reduction, possibly due to the quicker working of the slags. There was no excessive scorification of furnace bottoms or banks, nor did the iron have a detrimental effect on ladle linings. The high-manganese iron is of great assistance in the manufacture of high-grade and alloy steels, and steels made from it show increased yields with ordinary rolling mill practice.—J. W. D.

Manganese in the basic open-hearth steel process; Utilisation of ——. E. Killing. Stahl u. Eisen, 1920, 40, 1545—1547.

MANGANESE is utilised most efficiently when the charge is tapped when the manganese reduced from the slag is at a maximum; when bases are added in quantities corresponding with the absorption capacity of the slag, avoiding excess or deficiency; when the charge has the smallest possible content of acid elements such as phosphorus and silicon, so that large slag volume is avoided; when the temperature is as high as possible, and when manganese is added in the metallic state.—J. W. D.

Iron-carbon alloys; Graphitisation in ——. K. Honda and T. Murakami. Iron and Steel Inst., Sept., 1920. 8 pages. [Advance proof.]

FROM experiments with a pure white iron free from graphite, melted in 20-g. lots in an electric furnace, it is considered that graphitisation is the result of decomposition of solid Fe_3C, and that graphite does not separate directly from the liquid phase. The reaction is a catalytic one due to carbon monoxide or dioxide. At the high temperatures carbon monoxide is in part converted into carbon dioxide and carbon. The dioxide then reacts with Fe_3C as follows: $CO_2+Fe_3C=2CO+3Fe$. Carbon dioxide is again formed from the monoxide, and the Fe_3C is thus converted gradually into iron and graphite. A high melting temperature of 1300° C. or over hinders the formation of graphite. A sample melted at 1200° C., cooled to 1130° C., and quenched shows no graphite. If, however, the quenching temperature is lowered to 1050° C., full graphitisation occurs. If carbon monoxide or dioxide is passed through the melt, and the metal immediately cooled, a high degree of graphitisation is found. Air or iron oxide also favours the formation of graphite. Hydrogen or nitrogen produces no graphitisation. In alloys melted *in vacuo* graphite does not readily form.—F. C. Th.

Spheroidal cementite [in steel]; Formation of ——. K. Honda and S. Saito. Iron and Steel Inst., Sept., 1920. 7 pages. [Advance proof.]

IF a quenched carbon steel is reheated to a temperature below the Ac1 point the carbide of the sorbite becomes spheroidal. In hypereutectoid steels reheating to a temperature between Ac1 and that at which all the carbide passes into solution results in the formation of spheroidal cementite. Lamellar pearlite does not give spheroidal cementite when heated below the Ac1 point, but at or just above that temperature it becomes globular. Granular pearlite, however, becomes globular when heated below the Ac1 temperature. In low carbon steels the temperature interval in which formation of spheroidal cementite occurs is 730°—750° C. With higher carbon content the range widens rapidly, and with 1·6% carbon or over the range is 730°—850° C.—F. C. Th.

Steels; Rates of reaction in certain —— at 930° C. E. D. Campbell and B. A. Soule. Iron and Steel Inst., Sept., 1920. 6 pages. [Advance proof.]

Bars of steel 6 mm. square by 15 cm. long were quenched vertically in water from 930° C. They were then examined by means of measurements of thermo-electric potential against electrolytic iron from end to end to determine what differences are induced by the different conditions of cooling. In all freshly quenched steels the end which entered the water last had as a result of the more rapid cooling the higher thermo-electromotive potential. In a pure carbon steel (C 1·18%) the difference would indicate a change in constitution between the two ends equal to 8% of that due to tempering at 110° C. and 3% of that due to the total carbide concentration. Where silicon, nickel, or manganese was present the thermo-electric potential was higher than that due to carbides alone, and tempering at 110° C. resulted in an increase.—F. C. Th.

Chrome-nickel steels; Non-rusting ——. B. Strauss. Naturwiss., 1920, 8, 812—814. Chem. Zentr., 1920, 91, IV., 621.

Chrome steels show great resistance to corrosion, but without nickel have not the requisite mechanical properties. There are two groups of chrome-nickel steels, showing high resistance to corrosion but differing essentially in physical and chemical properties and in structure. To the first group belong steels having a martensitic structure and containing 10—15% Cr with 1—3% Ni. These are self-hardening. By heating slightly above the transition temperature, 680°—750° C., and cooling slowly or quickly, they assume a troostosorbitic structure and become workable. The second group of chrome-nickel steels, with 20—23% Cr and 6—9% Ni, have a polyhedral structure (austenite) and require a different heat treatment, consisting in heating to 1100°—1200° C. and cooling quickly. Unlike those of the first group, these steels are non-magnetic. In both groups the carbon content is 0·1—0·3%. Between the two groups lie steels with intermediate structure and unfavourable mechanical properties. The oxidation potential of these non-rusting steels is between that of copper and that of silver.—E. H. R.

Pyrites cinder; Desulphurising of ——. F. Fichter and E. Schaffner. Helv. Chim. Acta, 1920, 3, 869—872.

Secondary roasting for the removal of sulphur from pyrites cinder is ineffective below 1200° C., but reduction in an atmosphere of hydrogen at 1030° C. gives better results. In fact, pyrites and ferrous sulphide themselves may be reduced to iron in this way. Iron almost free from sulphur is also obtained by electrolytic deposition from a solution of pyrites cinder in very concentrated sodium hydroxide (*cf.* J., 1918, 659 A) or by heating the cinder with lime, kaolin, and charcoal in the electric arc. —J. C. W.

Alloys of aluminium and magnesium. D. Hanson and M. L. V. Gayler. Inst. of Metals, Sept., 1920. [Advance copy.] 27 pages.

A re-determination of the thermal equilibrium diagram of this series has been made. The existence of two compounds is indicated, Al_3Mg_2 and Al_2Mg_3, melting at 450° C. and 455° C. respectively. The latter compound does not occur exactly at a maximum on the liquidus. Three eutectics are present, namely between the α-solution and a solution rich in Al_3Mg_2, melting at 447° C. and extending from 13 to 37% Mg; between solutions rich in the compounds, melting at the same temperature, the horizontal extending from 38·5 to 42% Mg; and between the solution rich in Al_2Mg_3 and the δ-solution rich in magnesium, melting at 436° C., and extending from 60 to 88% Mg. The solid solution of Al_3Mg_2 in aluminium contains 12% Mg at 447° C. and 10% at room temperatures. The β solution extends from 36·7 to 38·5% Mg at temperatures below 447° C. The γ solution contains 42—59% Mg at 444° C. and 49—60% at 400° C. and at room temperature. At 486° C. magnesium holds 10% Al as Al_2Mg_3 in solution and at room temperature 9%.—F. C. Th.

[Aluminium] alloys; Light —— of high resistance. Grard. Rev. Mét., 1920, 17, 286—300.

Test-pieces of duralumin annealed at 450° C. gave the following results when tested in the longitudinal and transverse directions respectively: maximum stress, 32, 26 kg. per sq. mm.; elastic limit, 13, 12 kg. per sq. mm.; elongation, 18, 10%; impact test, 3, 2·5 kg.-m. On cold rolling the maximum stress fell to a minimum with between 15 and 20% reduction, after which it again rose slightly. The minimum value was 22 kg. per sq. mm. both longitudinally and tranversely. The elastic limit is raised by working, and with 20% or greater reduction nearly coincides with the tensile strength. The elongation is lowered rapidly to about 4% with 20% reduction, and then remains stationary up to 40% reduction. The resilience (impact value) falls to about 1 kg.-m. with 50% reduction. 50% reduction is the practical limit, further rolling leading to cracking. The material reduced 50% by rolling was used for the tests on the influence of annealing after cold work. The tests were carried out after ageing for 8 days. There are two important temperature ranges, *viz.*, 350°—375° C. and 475°—500° C., and the properties of the alloy annealed at each, taken in the direction of rolling, are:

	Elastic limit, kg. per sq. mm.	Maximum stress, kg. per sq. mm.	Elongation, %	Impact, kg.-m.
350° C., slowly cooled ..	6	20	20	6
,, air cooled	7	20	20	4·5
475° C., slowly cooled ..	12	28	16	4
,, air cooled	18	32	18	4

There are maxima in the elongation and resilience curves at 350° C. and 475° C., minima in the tensile strength and elastic limit curves at 350° C., and maxima of strength and elastic limit at 475° C. 350° C. is the best temperature for softening for machining. When the cold-worked alloy is quenched from 350° and 475° C. respectively, the mechanical properties are: elastic limit, 9, 20 kg. per sq. mm.; maximum stress, 20, 40 kg. per sq. mm.; elongation, 15, 20%; impact test, 3, 3·5 kg.-m.; 475° C. is the best quenching temperature for the final treatment. Quenched at 550° C. the alloy is softer, less ductile, and more brittle than when quenched at 475° C. After quenching at this latter temperature the material hardens by ageing fairly rapidly during the first 4 days, after which it becomes fairly steady. In this period of 4 days the maximum stress rises from 30 to 38 kg. per sq. mm., and the elastic limit from 10 to 23 kg. per sq. mm. The elongation and the resilience show considerable variations during the first 4 days, but after 8 days have about the same values as before ageing. Ageing is best effected by re-heating to 200° C. after quenching from 475° C. in water. The Brinell hardnesses (load 500 kg.) at various temperatures of the quenched and aged alloy are: ordinary temperature, 83; 100° C., 108; 200° C., 83; 300° C., 50; 400° C., 12.—F. C. Th.

Aluminium; Nickel-plating of ——. A. Mazuir. Ann. Chim. Analyt., 1920, 2, 335—336.

The aluminium is immersed for 2 mins. in a cold bath containing 8 g. Na_2O and 30 g. KCN per l., and

then thoroughly washed with water and scoured with milk of lime (1 $CaO:4H_2O$). After thorough washing it is immersed in a bath of a metal chloride, preferably manganese or iron chloride. A suitable bath contains 350 c.c. of hydrochloric acid of 22° B. (sp. gr. 1·18), manganese 2 g., and water 650 c.c., whilst a ferric chloride bath should contain 3 g. Fe per l. Finally the object is immersed in a bath of nickel sulphate (*e.g.*, 120 g. nickel sulphate and 50 g. of a double nickel sulphate), and electrolytically coated by means of a current within the limits of 2·5 and 3 volts, and ampérage of 1 to 1·5 per sq. dcm. The anodes are of thin sheet nickel plate. Plating is complete in 1½ hrs., and the aluminium is then washed with boiling water, and dried by means of compressed air.—C. A. M.

Zinc; Experimental furnace for the preparation of —— and the determination of the various products. O. Mühlhaeuser. Metall u. Erz, 1920, 17, 487—494.

MINUTE details accompanied by the necessary drawings are given of a small experimental plant for the distillation of zinc and the collection and treatment of the various products. The plant consists of a gas producer, retort, and combustion chamber, a condenser for the zinc, and scrubbing towers to remove the fume from the issuing gases. Exact instructions are given for working the furnace, together with three examples showing the results obtained from charges of ore, crude zinc (90·6% Zn), and zinc dust.—A. R. P.

Babbitt metal; Analysis of ——. H. C. Boehmer, J. R. Gordon, and C. W. Simmons. Canad. Chem. J., 1920, 4, 171—173.

ONE g. of filings is dissolved in 35 c.c. of strong sulphuric acid. After cooling, 5 c.c. of strong hydrochloric acid and 150 c.c. of water are added and, after standing for 1 hr., the lead sulphate is collected in a Gooch crucible, washed with dilute sulphuric acid, then with water, dried, ignited at a dull red heat for ½ hr., and weighed. The antimony in the filtrate is determined by titration with potassium bromate, using methyl orange as indicator. The titrated solution is reduced by boiling for 20 min. with 0·5 g. of antimony and 40 c.c. of strong hydrochloric acid, cooled in a current of carbon dioxide, and the tin titrated with the same bromate solution, using potassium iodide and starch as indicator. The reduction may also be effected by adding 9 g. of zinc and 40 c.c. of hydrochloric acid, 5 c.c. at a time, while passing carbon dioxide. When all the metal is dissolved, the solution is titrated as before.—A. R. P.

Metallurgical products not attacked by acids; Rapid method of disintegrating —— for analysis. I. Compagno. Giorn. Chim. Ind. Appl., 1920, 2, 554—555.

ALLOYS of iron with silicon, tungsten, chromium, etc., which are not attacked by mineral acids may be rapidly disintegrated by fusing the finely-powdered metal in a nickel crucible with a dry mixture of sodium carbonate (52%), potassium nitrate (20%), and coarsely-powdered magnesium (28%). When cold, the fused mass is acidified with a mineral acid and the solution boiled until gas ceases to be evolved.—C. A. M.

Malleability of metals and alloys; New method for determining ——. P. Ludwik. Stahl u. Eisen, 1920, 40, 1547—1551.

To obtain an approximate indication of the toughness and ductility of metals without preparing a special test-piece, a hardened cone with an angle of 90° at the point, such as is used in the Ludwik hardness test, is driven normally into the material under test near its edge until a crack is produced, the edge of the material being bulged outwards a distance, a. On account of the geometrical similarity of the mechanism of flow for different distances, k, of the point of the cone (before the test) from the edge, the ratio a/k is an approximate index of the malleability of the material in question independent of the actual value of k. This index can be converted into other useful comparative numbers.—J. W. D.

Impact tests [on metals]. A. Ono. Mem. Coll. Eng., Kyushu Imp. Univ., 1920, 2, 89—116.

AN error of ±0·1 mm. in the diameter of the hole (4 mm. diameter) drilled in certain types of test-pieces for impact tests may give rise to an error of ±1·5% in the result, which is insignificant. In steels with a banded structure marked irregularity occurs in impact test results. In one case four times as much work was required to break the piece as in other pieces of the same steel. Transverse tests were in general distinctly worse than longitudinal ones. Cold straining of mild steel lowers the resistance to impact, which is restored by annealing. In two cases examined, annealing at 770° C. and at 600° C. respectively was sufficient to restore the toughness. In repeated impact tests the effect of cold straining was not very marked. The effect of grain growth, however, is marked, as illustrated in the following tests on a steel containing 0·065% carbon. After annealing at 920° C. the steel withstood 1010 blows; after annealing, followed by straining (% strain=8%), 940; after annealing, straining, and again annealing at 450°, 500°, or 600° C., 1013; 700° C., 496; 800° C., 553; 900° C., 1104; 980° C., 572 blows.—F. C. Th.

Arsenic. Jones. *See* VII.

PATENTS.

Wrought iron; Manufacture of ——. E. E. Elliott. E.P. 153,523, 15.3.20.

A CHARGE of pig iron or cast iron, together with iron ore, purple ore, or other suitable ore, and tap cinder, is heated in a furnace in a receptacle having an open joint between the sides and bottom, and one or more joints in the sides through which the gases and impurities escape.—J. W. D.

Steel; Magnetic apparatus for heat treatment of ——. C. O. Bastian. E.P. 153,336, 25.3.19.

THE claim is for a method of determining the critical temperature of steel by heating it in a furnace surrounded by a magnetising coil, the change being indicated on a magnetic compass. —J. W. D.

Steel; Heat treatment of ——. C. P. Sandberg and J. C. W. Humfrey. E.P. 153,756, 20.10.19.

STEEL cooling from a temperature above its critical range is brought under magnetic influence, so that as soon as it has cooled to a temperature at which it acquires magnetic properties it becomes part of a magnetic field and attracts a magnet swinging close by, thus giving visual indication for controlling the cooling operation.—J. W. D.

Manganese steel; Process of making ——. W. G. Nichols, Assr. to American Manganese Steel Co. U.S.P. 1,356,551, 26.10.20. Appl., 21.6.20.

MANGANESE steel scrap is melted, and manganese ore is added in sufficient quantity to restore to the ultimate bath the desired proportion of manganese. —J. W. D.

Manganese steel; Making ——. W. G. Nichols, Assr. to American Manganese Steel Co. U.S.P. 1,359,268, 16.11.20. Appl., 15.8.18.

MANGANESE steel is recovered from scrap by melting ordinary steel scrap in an electric furnace, adding to the molten bath all the manganese steel scrap in

one charge, heating the bath by slow stages to the melting point of manganese steel, and adding ferromanganese in sufficient quantity to produce the desired alloy.—J. W. D.

Iron or steel article; Alloy-coated ——, and method of coating same. J. L. Schueler, Assr. to Keystone Steel and Wire Co. U.S.P. 1,357,907, 2.11.20. Appl., 15.7.16.

Iron or steel wire is drawn through a molten bath consisting of 91% of lead, 8% of antimony, and 1% of zinc, being removed in a vertical direction without wiping, so that excess metal on the wire drains back into the bath.—T. H. Bu.

Iron-silicon alloy; Process of treating ——. W. J. Beck and J. A. Aupperle, Assrs. to The American Rolling Mill Co. U.S.P. 1,358,408, 9.11.20. Appl., 19.3.19.

Annealed sheets of iron-silicon alloy are pickled so as to leave a coating of silicious compounds, and then cold rolled to impregnate the surface with these compounds.—T. H. Bu.

Steel; Case-hardening ——. J. D. Cutter, Assr. to Climax Molybdenum Co. U.S.P. 1,358,831, 16.11.20. Appl., 28.6.20.

A low-carbon steel containing Ni, Cr, and Mo, each not exceeding 1%.—B. M. V.

Steel; Process of treating ——. N. C. Einwechter. U.S.P. 1,359,238, 16.11.20. Appl., 5.5.19.

Vanadium steel is heated slowly to 1430°—1440° F. (about 775°—780° C.), quenched in water at 60° F. (15° C.) until vibration ceases, and then placed in an oil bath.—J. W. D.

Iron plate; Process of removing scale from ——. Method of simultaneously annealing and descaling tin-plate. I. M. Scott. U.S.P. (A) 1,359,281 and (B) 1,359,282, 16.11.20. Appl., (A) 23.4.20 and (B) 30.6.20.

(A) The plates are heated in contact with powdered ferrosilicon at a sufficiently high temperature to reduce the scale to metal. (B) The plates are packed in annealing boxes with carbonaceous material between them and heated to a temperature sufficient to reduce the scale and anneal the plates without carbonising them to any considerable extent. —A. R. P.

Ferro-chromium; Process for increasing the yield of chromium in the aluminothermic production of carbon-free —— or multiple alloys thereof containing chromium. T. Goldschmidt, A.-G. E.P. 152,990, 29.9.20. Conv., 14.10.19.

A certain amount of iron oxide, *e.g.*, rolling-mill scale, is added to the charge of aluminium and chrome-iron ore before igniting. In the manufacture of multiple alloys of ferro-chromium, oxides of other metals, such as cobalt, nickel, tungsten, molybdenum, or vanadium, are added to the charge. —A. R. P.

Bearing metals. Metallbank u. Metallurgische Ges. A.-G. E.P. 140,790, 24.3.20. Conv., 18.1.17.

Alloys suitable for bearing metals consist essentially of lead and not more than 5% of barium, and may contain in addition light metals, especially sodium, calcium, and magnesium, and aluminium or small quantities of heavy metals such as copper, zinc, tin, manganese, etc.—J. W. D.

Magnetic separators. F. Krupp A.-G. Grusonwerk. E.P. 145,442, 18.6.20. Conv., 2.8.18.

Each magnet of a magnetic separator of the type in which two or more magnetic fields operate one behind the other, is provided with a separate supply device, capable of being inclined at any angle to the magnet and independently movable in a vertical direction towards or away from it. The discharge ends of the supply devices are curved so as to be always parallel to the edge of the rotating magnetic annulus, and the whole apparatus is mounted on a pivot in order that the speed of the material may be simultaneously accelerated or retarded for all the magnets.—A. R. P.

Ores and the like; Process and apparatus for washing ——. C. A. Edgley. E.P. 153,503, 3.2.20.

The ore, *e.g.*, chloridised roasted ore, is admitted to the centre of a flat-bottomed circular basin having a rotary stirrer, and from the side of which extends a discharge trough with bottom inclined slightly upwards, containing a conveyor. Water or other suitable liquid is allowed to flow into the discharge trough towards the basin, in the opposite direction to the conveyor, and after it has washed the ore, it flows out of the circular basin. The ore is discharged by the conveyor to a similar unit if required.—T. H. Bu.

Aluminium alloys. H. C. Hall, and Rolls-Royce, Ltd. E.P. 153,514, 25.2.20.

An aluminium alloy contains Cu 0·1—3·0%, Ti 0·1—2%, Zn 6·0—16·0%, Fe not exceeding 0·6%, Si not exceeding 0·4%, other elements not exceeding 0·4%. Part of the aluminium, not exceeding 3%, may be replaced by not more than 1·5% of either Sb or Mg, or not more than 1·5% Sb and 1·5% Mg.—J. W. D.

Aluminium alloys. H. C. Hall, and Rolls-Royce, Ltd. E.P. 153,823, 25.2.20.

Claim is made to aluminium alloys containing either Cu 4—12%, Ti 0·12—2·2%, Fe not exceeding 0·6%, Si not exceeding 0·4%, other elements not exceeding 0·5%, or an alloy of similar composition in which not exceeding 3% of the aluminium is replaced by not exceeding 1·5% of antimony and/or not exceeding 1·5% of magnesium.—J. W. D.

Alloy. F. E. Carter, Assr. to Baker and Co., Inc. U.S.P. 1,355,811, 19.10.20. Appl., 15.2.19.

An alloy containing 83·3% Au and 16·7% Ni has the colour of, and is capable of being worked in the same way as, platinum.—J. W. D.

Alloy. F. E. Carter, Assr. to Baker and Co., Inc. U.S.P. 1,357,272, 2.11.20. Appl., 20.1.20.

The alloy consists of platinum with 5—15% Au, 0·5—5·0% Ag, and 0·5—5·0% Pd.—A. R. P.

[Alloy for] apparatus for high temperature uses. Chemical ware or technical apparatus and alloys for making same. F. A. Fahrenwald. U.S.P. (A) 1,357,549 and (B) 1,357,550, 2.11.20. Appl., 25.8.19.

(A) An alloy of iron with 10—20% each of cobalt and chromium, and at least 0·2% each of carbon, silicon, and manganese. (B) The alloy contains 40—60% Cr, together with 10—20% of one or more metals of the chromium group, alloyed with one or more iron group metals.—A. R. P.

Zinc alloy. H. Goldschmidt and K. Müller, Assrs. to The Chemical Foundation, Inc. U.S.P. 1,358,147, 9.11.20. Appl., 19.4.17.

The alloy contains 0·5—6% of aluminium and 0·25—2% of manganese.—T. H. Bu.

Alloy; Antifriction —— and method of manufacture. L. M. Parkhurst, Assr. to H. Kramer and Co. U.S.P. 1,359,194, 16.11.20. Appl., 8.3.20.

An alloy containing approximately Pb 79%, Sb 12%, Sn 6%, Cu 2·5%, and P 0·5%.—J. W. D.

Corrosion; Prevention of ——. M. A. Adam. E.P. 153,616, 13.5.19.

Iron apparatus, *e.g.*, a tank, pump, or pipe, carry-

ing corrosive solutions of metals which are capable of being deposited electrolytically, is made the cathode in an electric circuit, the anode being, preferably, carbon, and a current is passed through the solution at such a potential that it deposits a metallic protective coating on the iron at a speed at least as rapid as that at which the solution re-dissolves it. A heater for such corrosive solutions consists of a water-jacketed iron vessel containing an anode, preferably carbon, arranged to maintain contact with the solution throughout its passage through the vessel. Hot water is circulated through the jacket. The invention may be applied to the protection of iron vessels for use in detinning tin-plate scrap.—A. R. P.

Briquetting ores. W. Tyrrell, Assr. to New Era Iron and Steel Corp. U.S.P. 1,356,100, 19.10.20. Appl., 29.5.19.

ORE briquettes are made with a binding material having a higher fusing point than the metals in the ores, the composition of the binding material by weight being sodium sulphate 2 pts., diatomaceous earth 2, concentrated lye 2, magnesium carbonate 1 pt.—J. W. D.

Smelting furnace for lead ores and the like. J. Labarthe. U.S.P. 1,356,159, 19.10.20. Appl., 30.9.19.

AN elongated reduction furnace has an opening at the top extending the length of the furnace, and closed by a sliding door. Below the opening are vents for fumes and gases. Ore conveying and dumping compartments, each one-half the length of the furnace, travel on a track adjacent to the opening in the top of the furnace.—J. W. D.

Furnace; Metallurgical ——. H. B. Bryson. U.S.P. 1,358,703, 16.11.20. Appl., 26.9.17.

IN a process of making steel direct from iron ore, scrap, or the like, the materials are heated in a carbon-lined furnace, the molten metal being covered with a vitreous slag so as to maintain conditions similar to crucible conditions.—J. W. D.

Annealing metal castings. D. MacIntosh. U.S.P. 1,356,644, 26.10.20. Appl., 11.7.19.

THE castings are imbedded in a large quantity of granular calcium carbonate, heated to a high temperature, and then gradually cooled.—J. W. D.

Solder. B. E. Newell. U.S.P. 1,357,297, 2.11.20. Appl., 8.11.19.

A MIXTURE of 1 pt. of ammonium chloride, 2 of borax, 5 of mercury, 20 of block tin, and 26 pts. of lead.—A. R. P.

[*Copper ores;*] *Metallurgical process* [*for* ——]. W. E. Greenawalt. U.S.P. 1,357,495, 2.11.20. Appl., 10.6.18.

COPPER ores are leached with acid, and the resulting rich solution of copper salts is electrolysed to produce metallic copper and to oxidise the salts of metals of a variable valency. The wash liquors from the leaching operation are treated to precipitate copper sulphide, which is mixed with the rich solutions, after first reducing them with sulphur dioxide, and serves to keep them reduced during the electrolysis.—A. R. P.

Copper ores; Process of treating ——. *Process of treating copper ores with an SO_2 solution for the recovery of the copper therefrom.* N. C. Christensen. U.S.P. (A) 1,357,952 and (B) 1,358,619, 9.11.20. Appl., (A) 30.9.19, (B) 4.4.19.

(A) COPPER is precipitated as a cupro-cupric sulphite by addition of copper to a sulphite solution. (B) Copper ores are lixiviated with a solution containing sulphur dioxide, and copper precipitated as a cupro-cupric sulphite from the resulting liquor by addition of cuprous oxide.—J. S. G. T.

Stove for blast-furnaces and gas-producers; Air heating ——. T. Aramaki. U.S.P. 1,357,675, 2.11.20. Appl., 30.4.19.

THE body of the stove is provided with a brick wall having a refractory brick lining on the inner side and a reinforced comparatively non-conducting concrete covering on the outer side.—J. W. D.

Titanium; Recovery of —— *from its ores.* O. T. Coffelt. U.S.P. 1,357,690, 2.11.20. Appl., 6.12.18.

TITANIUM ores containing iron are digested with sulphuric acid of 77—85% strength, and the titanium deposited from the solution of iron and titanium sulphates formed.—T. H. Bu.

Cupola treatment of metals. H. Koppers, Assr. to Koppers Development Corp. U.S.P. 1,357,780, 2.11.20. Appl., 3.9.20.

A POOL of slag is maintained continuously in the hearth of the cupola in the presence of incandescent carbon that has sunk below the level of the air blast. The re-melted iron passes through this pool of slag and gives up sulphur to the slag.—J. W. D.

Blast treatment of metals. H. Koppers, Assr. to Koppers Development Corp. U.S.P. 1,357,781, 2.11.20. Appl., 3.9.20.

THE slag and molten metal are continuously maintained at constant levels at the bottom of the charge, so as to prevent sudden sinking of the charge. At the same time a portion of the furnace gas is withdrawn between the top gas outlet and the tuyères so as to check fusion in the stack and to insure gradual sinking of the charge.—J. W. D.

Crucible treatment of metals. H. Koppers, Assr. to Koppers Development Corp. U.S.P. 1,357,782, 2.11.20. Appl., 3.9.20.

THE crucible has a foraminous partition dividing it into upper and lower compartments, so that the molten metal charged into the upper compartment flows through the lower compartment in the form of a spray. The slag and molten metal in the lower compartment are maintained at constant levels.
—J. W. D.

Detinning; Method of ——. C. F. Carrier, jun., Assr. to The Vulcan Detinning Co. U.S.P. 1,358,136, 9.11.20. Appl., 5.8.11. Renewed 7.8.20.

SEPARATE portions of tinned scrap are treated in separate successive stages, first with anhydrous chlorine so extremely diluted that reaction with the iron of the scrap is impossible until the greater portion of the tin is removed, and then with concentrated chlorine until detinning is complete.
—T. H. Bu.

Platinum and other metals; Method of extracting —— *from their ores.* S. S. Sadtler. U.S.P. 1,358,248, 9.11.20. Appl., 8.12.16.

THE ore is mixed with a practically saturated solution containing alkali metal ions to form a pulp through which an electric current is made to pass, while the pulp is agitated to bring its particles into contact with a mercury electrode by which the current is introduced.—T. H. Bu.

Ores; Process for calcining ——. W. H. Corbould. U.S.P. 1,358,293, 9.11.20. Appl., 7.10.19.

FINELY pulverised copper ores and gangue are heated in a roasting furnace while being subjected alternately to air at a pressure above atmospheric and a partial vacuum.—T. H. Bu.

Magnetisable material; Process of treating ——. T. D. Yensen, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,358,810, 16.11.20. Appl., 4.4.19.

A METALLIC material is raised to a high tempera-

ture, short of fusion, in an oxidising atmosphere and then slowly cooled, in order to improve its magnetic qualities.—B. M. V.

Smelting volatile ores; Process and apparatus for ——. W. D. Kilbourn, Assr. to United States Smelting, Refining and Mining Co. U.S.P. 1,358,856, 16.11.20. Appl., 14.7.17.

A BLAST furnace for smelting volatile ores comprises a comparatively low shaft having a reducing chamber at its lower end, a grate at the bottom of the reducing chamber for supporting a comparatively low column of ore, into which an air blast is directed through a series of tuyères in the shaft near the bottom of the reducing chamber. A heat-radiating crucible is mounted below the grate. Means are provided for regulating the downward flow of air through the grate, and for removing volatilised oxide from the upper end of the furnace. —J. S. G. T.

Metallic articles; Method of producing formed ——. C. L. Gebauer. U.S.P. 1,359,353, 16.11.20. Appl., 16.10.18.

A FINELY divided metallic substance is pressed to the desired shape and size under great pressure and then heated to such a temperature that the particles become sintered together without fusion.—A. R. P.

Vanadium; Process for recovering —— *from certain iron ores.* W. M. Goodwin and A. F. G. Cadenhead, Assrs. to W. L. Goodwin and W. P. Firth. U.S.P. 1,359,473, 16.11.20. Appl., 4.4.19.

IRON ore containing vanadium is treated in a furnace to produce a pig iron containing all the vanadium and certain other elements in the ore. The pig iron is decarbonised so as to produce a mild steel and a slag containing all the vanadium, and the latter is put through the original process again with a fresh charge of ore. By continuing the process several times it is possible to produce a high-grade ferro-vanadium.—A. R. P.

Vanadium; Process for recovering —— *from certain iron ores.* W. M. Goodwin and A. F. G. Cadenhead. E.P. 153,926, 16.5.19.

SEE U.S.P. 1,359,473; preceding.

Tin; Method of recovering —— *from stanniferous waste products.* T. A. Eklund. U.S.P. 1,359,494, 23.11.20. Appl., 5.2.20.

SEE G.P. 316,111 of 1919; J., 1920, 303 A.

Magnesium or alloys thereof and chlorine; Process and apparatus for electrolytic decomposition of anhydrous magnesium chloride and production of ——. *Production of magnesium or alloys of magnesium and by-products.* E. A. Ashcroft. U.S.P. 1,359,653—4, 23.11.20. Appl., 12.8.19.

SEE E.P. 152,402—3 of 1919; J., 1920, 788 A.

Alloy for cable-casings and the like; Metal ——. D. Stenquist. U.S.P. 1,360,045, 23.11.20. Appl., 16.10.19.

SEE E.P. 136,143 of 1919; J., 1920, 602 A.

Furnaces. E.P. 153,511. *See* I.

XI.—ELECTRO-CHEMISTRY.

Ferrous and ferric [hydr]oxides; Electrolytic formation of the alkali salts of ——. G. Grube and H. Gmelin. Z. Elektrochem., 1920, **26**, 459—471. (*Cf.* J., 1920, 363 A.)

IRON, which has been activated by cathodic treatment, passes into solution in 40% sodium hydroxide in the absence of air, as sodium ferrite, when anodically polarised by a low current density. At 80° C., with a current density of 0·166 amp. per sq. dcm., a 0·026 molecular solution of ferrite may be obtained. Iron may also pass into solution in the hexavalent condition, but not in the trivalent condition in strong alkaline solutions. The electrolytic formation of sodium ferrite is brought about on platinum electrodes either by the anodic oxidation of an alkaline solution of ferrous hyroxide or by the cathodic reduction of a solution of sodium ferrate. (*Cf.* J.C.S., Jan., 1921.)—J. F. S.

Townsend cell. Hooker. *See* VII.

Electro-analytical practice. Böttger. *See* XXIII.

PATENTS.

Electric furnaces; Heating elements for ——. E. L. Smalley. E.P. 153,701, 22.8.19.

A REMOVABLE heating element comprises a hollow muffle, the outer surface of which is provided with longitudinal grooves in which lie the parallel strands of a preformed grid resistor of comparatively rigid material. The muffle is shorter than the furnace housing, and the bends of the grid are supported in recesses formed on the end walls of the furnace. Alternatively, the hollow muffle may be provided with end collar portions extending beyond the bends of the grid.—J. S. G. T.

Furnace; [Protecting resistors of] electric [crucible] ——. R. R. Reed. U.S.P. 1,357,901, 2.11.20. Appl., 27.3.20.

DURING the operation of the furnace, the resistors are embedded in a bath of molten glass surrounding the crucible. The crucible and resistors are mounted so as to allow for expansion and contraction of the glass.—J. S. G. T.

Furnace; [Tilting] electric ——. S. N. Castle. U.S.P. 1,358,617, 9.11.20. Appl., 14.6.18.

ALTERNATING current from a transformer is supplied to the electrodes of a tilting electric furnace through leads, the reluctance of which is substantially that of air, and which are supported by the upper parts of projections extending upwards from the furnace structure and tilting therewith.—J. S. G. T.

Graphite articles [electrodes]; Method of manufacturing ——. F. R. Kemmer, Assr. to Republic Carbon Co. U.S.P. 1,357,290, 2.11.20. Appl., 18.12.19.

CARBON articles, such as electrodes, are graphitised in an electric furnace in which the current flows transversely to the largest dimensions of the articles. The articles are arranged in the furnace with their longest dimensions vertical.—J. S. G. T.

Electrolytic cell. O. H. Jewell, Assr. to Chlorine Products Co. U.S.P. 1,357,400, 2.11.20. Appl., 4.3.20.

THE cathode of an electrolytic cell comprises a conducting portion, a diaphragm composed of an organic substance resistant to the action of caustic alkali, and porous material protecting the exposed face of the diaphragm from the anolyte. —J. S. G. T.

Electrolytic cell and method of using the same [: Cathode for ——]. W. M. Jewell, Assr. to Chlorine Products Co. U.S.P. 1,357,401, 2.11.20. Appl., 21.4.19.

A CATHODE is constituted of a hollow body entirely surrounded by a porous diaphragm in contact with it over its entire area.—J. S. G. T.

Electrolytic cell. T. B. Walker. U.S.P. 1,357,485, 2.11.20. Appl., 6.1.17.

THE level of electrolyte in a closed electrode compartment of the cell is controlled by a float operating in a chamber communicating with the elec-

trode compartment by channels respectively above and below the normal level of electrolyte. The movements of the float are transmitted through a liquid seal pipe, one end of which is open to the atmosphere, the other end being sealed by the liquid normally in the float chamber.—J. S. G. T.

Diaphragm for electrolytic cells. M. W. Krejci and G. E. Johnson. U.S.P. 1,358,858, 16.11.20. Appl., 16.1.20.

THE base of the diaphragm is composed of loose filaments of vitrified material compressed so that the diaphragm operates by osmosis.—J. S. G. T.

Electrolytic cell [; Diaphragm for ——]. B. Thomas. U.S.P. 1,359,002, 16.11.20. Appl., 10.6.18.

A DIAPHRAGM of an electrolytic cell is composed of arenaceous quartz sintered together.—J. S. G. T.

Storage batteries; Separator for ——. O. C. Hirsch and A. R. Harnes. U.S.P. 1,358,207, 9.11.20. Appl., 2.1.20.

A WOODEN plate is treated with high-pressure superheated steam and then with an aqueous solution of sulphuric acid to obtain a relatively porous separator for storage batteries—J. S. G. T.

Depolarising agent for dry batteries, and process of making same. C. Ellis, Assr. to National Carbon Co. U.S.P. 1,358,626, 9.11.20. Appl., 31.10.17.

A DEPOLARISING agent possessing a greater conductivity lag than ordinary pure hydrated manganese dioxide is composed of precipitated slightly hydrated manganese material containing more than 95% of MnO_2.—J. S. G. T.

[Zinc] battery anodes; Process of making ——. H. F. French, Assr. to National Carbon Co., Inc. U.S.P. 1,359,244, 16.11.20. Appl., 27.12.15.

A ZINC electrode is shaped in a mould heated to substantially the melting point of zinc, and the mould is then cooled so that the electrode solidifies slowly. —J. S. G. T.

Electrolytic cells; Indicators ["lanterns"] for ——. I. H. Levin. E.P. 154,089, 31.12.19.

Electrical precipitation. U.S.P. 1,357,886. *See* I.

Gas purification. U.S.P. 1,358,030—2. *See* I.

Treating fibres. U.S.P. 1,357,580. *See* V.

XII.—FATS; OILS; WAXES.

Oils; Polymerisation of ——. H. Wolff. Kolloid Zeits., 1920, 27, 183—188.

A THEORETICAL discussion of the processes occurring during the "polymerisation" of linseed oil and tung oil, and the various changes both physical and chemical brought about by the treatment. (*Cf.* Morrell, J., 1915, 105.)—J. F. S.

Ricinoleic acid; Position of the double bond in ——. K. Stosius and K. Wiesler. Biochem. Zeits., 1920, 111, 1—8.

ON oxidising ricinoleic acid with an alkaline solution of potassium permanganate, a mixture of azelaic and suberic acids was obtained. By neutralising the mixture with a known amount of sodium hydroxide and then adding in succession, in four equal portions, the quantity of hydrochloric acid necessary to liberate the free acids and extracting each fraction with ether, azelaic acid, m.p. 106° C., was obtained in the first fraction, and suberic acid, m.p. 140° C., in the last fraction. The other fractions contained a mixture of both acids. It is suggested that azelaic and suberic acids are formed by the oxidation of two different isomers of ricinoleic acid, which arise by displacement of the double bond.—S. S. Z.

Soap; Possibility of substituting inorganic colloids for ——. G. Weissenberger. Kolloid Zeits., 1920, 27, 69—78.

AN inorganic substitute for soap may be prepared from a mineral found at Gaura, Siebenbergen, Austria. The mineral, dried at 105° C., has the composition: SiO_2 71·05%, Al_2O_3 15·40%, Fe_2O_3 1·33%, FeO 0·21%, CaO 1·87%, MgO 0·84%, K_2O 3·28%, Na_2O 2·67% and H_2O 4·18%. When ground finely with water it gives a stable suspension, and on keeping deposits a grey powder, which is colloidal and strongly hydrated and possesses the essential properties of soap.—J. F. S.

PATENTS.

Oils and the like; Method and apparatus for extracting ——. R. Wells, Assr. to Cobwell Corp. U.S.P. 1,357,365, 2.11.20. Appl., 29.2.16.

FOR the extraction of oils or the like from materials containing water, the material is supported in a chamber so as to be exposed above and below, a solvent for the oil, insoluble in water, is run in to an amount sufficient to immerse the material, and the temperature is then raised to a point where the combined vapour pressures of solvent and water are equal to or greater than the vapour pressure in the chamber, more solvent being added as required to maintain the amount in the chamber substantially constant.—A. de W.

[Oxidised] oils; Method of removing or decreasing objectionable odours from treated ——. J. E. Booge, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,357,836, 2.11.20. Appl., 13.6.18.

THE objectionable odours from partly oxidised vegetable or animal oils are removed or decreased by blowing the oils with a dry inert gas at 105°—130° C.—A. de W.

Cleaning agents; Manufacture of ——. F. M. Mayrhofer. E.P. 146,222, 26.6.20. Conv., 27.5.19.

CLEANING agents, which in presence of water yield colloidal materials, are obtained by mixing a dry hydrated or anhydrous, non-hygroscopic, water-soluble aluminium salt, *e.g.*, aluminium sulphate, with a soluble or an insoluble hydrated or anhydrous carbonate, bicarbonate, or percarbonate, *e.g.*, sodium carbonate, bicarbonate, or percarbonate, or magnesium carbonate. A bleaching compound may also be added to the mixture.—A. de W.

Cleaning process. F. Steimmig. G.P. 325,796, 24.5.16.

GELATINOUS silicates are used. A suitable gel is obtained by adding a solution of 24 g. of water-glass of 38°—40° B. (sp. gr. 1·36—1·38) in 1 l. of water to a solution of 20 g. of crystallised magnesium chloride in 1 l.—E. H. R.

Fatty and oily matters; Process for the extraction of —— from wet sludges and other substances. A. J. Stephens. From Sharples Specialty Co. E.P. 153,668, 11.8.19.

SEE U.S.P. 1,328,047 of 1920; J., 1920, 240 A.

Oil filters. J. Potter. E.P. 153,760, 29.10.19.

Cellulose acetate composition. U.S.P. 1,357,335. *See* V.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Constituents of ——. Amyrins from Manila elemi resin and their separation. A. Zinke, A. Friedrich, and A. Rollett. Monatsh. Chem., 1920, **41**, 253—270.

CRUDE amyrin benzoate may be separated, by fractional crystallisation from acetone, into α- and β-amyrin benzoates, the α-compound being subsequently purified by alternate treatments with ethyl acetate and acetone. (*Cf.* J.C.S., Jan., 1921.)
—T. H. P.

Polymerisation of oils. Wolff. *See* XII.

PATENTS.

Phenolic aldehyde condensation products; Process for the preparation of ——. A. T. and F. E. Birkby. E.P. 153,494, 13.1.20.

A MIXTURE of 500 pts. by vol. of phenol or its homologues, 450—550 pts. by vol. of 40% formaldehyde, and 2—6% by vol. on the phenol of a mixture of 20 pts. by vol. of sulphuric acid (sp. gr. 1·84) and 80 pts. of water, is heated in a digester at 60°—80° C., with agitation for 1—2 hrs. Agitation is then discontinued, the watery layer run off, and a neutralising agent, *e.g.*, milk of lime, added in excess, with agitation. The residual water is then removed from the resinous mass by distillation under reduced pressure.—A. de W.

Phenol resin condensates; Production of ——. F. Scudder and R. Pettigrew. E.P. 153,796, 16.12.19.

A THIN liquid phenolic condensation product, specially adaptable for the impregnation of friction blocks, stair treads, etc., is obtained by allowing sodium sulphite, 40% formaldehyde, and carbolic acid, in about the proportions of 50, 1000, and 1000 pts. by weight respectively, to react together for 3 or 4 days at ordinary atmospheric temperature with occasional stirring. The supernatant aqueous layer is removed, and the lower layer, containing 55—56% of dry resin, may be used for impregnating porous articles, which are then dried at 80°—90° C. and heated under pressure to harden the resin.
—A. de W.

Phenolic condensation products; Manufacture of ——. L. V. Redman, A. J. Weith, and F. P. Brock, Assrs. to Redmanol Chemical Products Co. U.S.P. 1,358,394, 9.11.20. Appl., 10.3.19.

A FUSIBLE, substantially anhydrous phenolic condensation product corresponding with a reaction between a phenolic substance and a methylene compound in proportions affording at least two phenolic groups to each methylene group, is mixed with a filler and with a methylene compound capable of reacting with the condensation product under anhydrous conditions, the methylene compound being in sufficient amount to give to the product approximately one methylene group to each phenolic group. The mixture is then subjected to a quick-moulding operation, removed from the mould, and subjected to heat treatment until a substantially infusible product is obtained.—A. de W.

Diatomaceous earth [for use in paints]; Method of grinding ——. J. E. Schneider, Assr. to Seattle Asbesto-Mine Co. U.S.P. 1,357,480, 2.11.20. Appl., 5.5.19.

A MINERAL agent which prevents the particles of diatomaceous earth from clogging together when finely ground is added to the latter, and the mixture subjected to a very fine pulverising action. (*Cf.* U.S.P. 1,317,225 of 1919; J., 1919, 916 A.)
—A. de W.

Rouge; Apparatus for manufacturing ——. C. L. Waisner, Assr. to Mirror Rouge Co. U.S.P. 1,357,664, 2.11.20. Appl., 3.5.18.

THE apparatus comprises a rotary roasting chamber and a vertical support provided with a chamber having its side walls furnished with enlarged openings and its top wall with a stack leading from the chamber. The roasting chamber extends through one chamber into and across the body of the other chamber and partly into the other opening, the latter being provided with a closure.—A. de W.

Coumarone resin; Purifying and raising the melting point of ——. Rütgerswerke A.-G. G.P. 325,575, 18.10.18.

THE resin is treated with concentrated sulphuric acid in the presence of a solvent, the solution is neutralised with compounds of alkaline earths or heavy metals, insoluble matter is separated, and the solvent is removed.—L. A. C.

Iron compounds [pigments]; Process of manufacturing ——. E. C. R. Marks. From West Coast Kalsomine Co. E.P. 153,792, 9.12.19.

SEE U.S.P. 1,327,061 of 1920; J., 1920, 231 A.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Action of light on ——. B. D. Porritt. Indiarubber J., 1920, **60**, 1159—1162.

RUBBER in balloon fabrics can be protected against the action of sunlight by the incorporation of a small proportion of litharge or of an organic dye of suitable colour. In the latter case the effect is probably one of light filtration, because a rubber solution exposed to ultraviolet light was effectively protected—as judged by its viscosity—not only when a little Sudan III. was mixed with the solution but also when the bottle containing the solution was surrounded by a benzene solution of Sudan III. The physical changes produced by the mastication of rubber are not necessarily the same as the initial effects of exposure to light and air. Masticated rubber after being stored in the dark tends to "recover" somewhat from the mechanical treatment, but oxygen appears to retard the recovery process because the surface layers of the rubber yield less viscous solutions than the interior. With solutions of lightly masticated rubber also there is a tendency to slight increase in viscosity on storage in the dark.—D. F. T.

PATENTS.

Rubber; Manufacture of ——. P. Schidrowitz, W. Feldenheimer, and W. W. Plowman. E.P. 153,343, 2.6.19.

CLAY mixed with sufficient water to form a pasty mass is treated with a "deflocculating agent," such as an aqueous solution of sodium carbonate, lime, or ammonia, and is then dried. The product forms a valuable compounding ingredient for rubber and imparts toughness and increased rate of vulcanisation.—D. F. T.

Rubber; Processes of reclaiming ——. J. Young and W. W. Benner. E.P. 153,646, 6.8.19.

SEE U.S.P. 1,324,093 of 1919; J., 1920, 165 A.

XV.—LEATHER; BONE; HORN; GLUE.

Chrome tanning. II. Determination of the basicity figure of one-bath chrome liquors. D. Burton and A. M. Hey. J. Soc. Leather Trades' Chem., 1920, **4**, 272—276.

CARBON dioxide functions as an acid in a chrome liquor, hence the present method (see Leather Chem.

Pocket Book, p. 124) of determining acid in such liquors by adding alkali to the boiling solution is inadequate, since it fails to take account of carbonic and other volatile acids. It is proposed that $N/2$ alkali should be run into the cold diluted chrome liquor in presence of phenolphthalein and that the addition should be continued during the period of heating up to the boiling point, and then until the pink colour persists after boiling for 1 min. —D. W.

Gelatin gels; Theory of the tanning (hardening) process in dilute —— with formaldehyde. L. Reiner. Kolloid Zeits., 1920, 27, 195—197.

Two to three per cent. solutions of formaldehyde harden 5% gelatin solutions in a few minutes, whilst a 1% solution of formaldehyde requires several days. Hardened gelatin softens at elevated temperatures, the temperature of softening being dependent on the amount of hardening and the concentration of the gelatin, but higher than the melting point of the untreated material. The softening of the hardened gelatin commences at the centre of the mass and spreads throughout the whole, and on raising the temperature sufficiently the mass becomes liquid. If the softening temperature is above 90° C., complete liquefaction is no longer possible. The hardening takes place more readily on the surface and at the walls of the containing vessel. On cooling a melted hardened gelatin it solidifies at a temperature below the solidification point of the untreated material. The hardening process is reversible, for on heating hardened gelatin with a little water at 100° C., formaldehyde is evolved and the gelatin regains its original physical properties. The hardening process may be stopped and reversed by the addition of small quantities of ammonia. (*Cf.* J.C.S., Jan., 1921.)—J. F. S.

Gelatin; Swelling of —— in acids. W. R. Atkin. J. Soc. Leather Trades' Chem., 1920, 4, 268—271. (*Cf.* J., 1920, 792 A.)

THE author shows that the results of Loeb (*cf.* J., 1919, 331 A, 548 A; 1920, 797 A) on the effect of acid on the properties of gelatin are in close agreement with those obtained by Procter and his collaborators, and thus afford additional evidence as to the soundness of the Procter-Wilson theory of the swelling of gelatin in acids (J., 1916, 645; 1917, 92). The actual hydrion concentration is the factor which determines swelling, irrespective of the nature of the acid except in the case of sulphuric acid. Other dibasic and tribasic acids behave like monobasic acids. Previous work on this subject in which hydrion concentrations have not been determined is of little value. (*Cf.* J., 1918, 313 A, 314 A.) —D. W.

Gelatin mixtures; Electrical conductivity of —— and their behaviour during the transition of gelatin. F. Rettig. Kolloid Zeits., 1920, 27, 165—172.

THE specific conductivity of gelatin-water mixtures at 18° C. increases rapidly with increase in concentration, and approaches a maximum value. The addition of small amounts of potassium chloride, bromide, and sulphate to gelatin-water mixtures increases the conductivity to values which are greater than those of aqueous solutions of the added salts of the same concentration. When gelatin is heated to 80° C., it is converted into β-gelatin, and the conductivity is irreversibly increased. The velocity of the change increases with the duration and temperature of the heating and is greater in dilute mixtures than in concentrated mixtures. (*Cf.*, J. C. S., Jan., 1921.)—J. F. S.

Gelatin; Amino-acids of ——. H. D. Dakin. J. Biol. Chem., 1920, 44, 499—529.

BY employing the new butyl alcohol method of extracting amino-acids (J., 1919, 196 A) considerable advances in our knowledge of the constituents of the gelatin molecule have been made. At least 91% of the molecule has now been satisfactorily accounted for, the proportions of the various amino-acids found being: glycine 25·5, alanine 8·7, leucine 7·1, serine 0·4, phenylalanine 1·4, tyrosine 0·01, proline 9·5, hydroxyproline 14·1, aspartic acid 3·4, glutamic acid 5·8, histidine 0·9, arginine 8·2, lysine 5·9, ammonia 0·4; aminobutyric acid, valine, isoleucine, and hydroxyglutamic acid were not detected. (*Cf.* J.C.S., Jan., 1921.) —J. C. D.

PATENTS.

Glue; Process of manufacturing fish ——. E. Knudsen. E.P. 153,526, 22.3.20.

FISH offal is bleached by means of a solution prepared by dissolving zinc in aqueous sulphurous acid, and is neutralised by steeping in lime water and finally cooked with water. Before bleaching, the offal may be treated with dilute hydrochloric acid, *e.g.*, for 24 hrs. in acid of 6° B. (sp. gr. 1·043), to dissolve mineral matter, and then neutralised with lime water.—J. H. L.

Glue; Process of manufacturing vegetable ——. V. G. Bloede. U.S.P. 1,357,310, 2.11.20. Appl., 27.11.17.

STARCH is mixed with cold water containing in solution a salt of a base which has the property of coagulating starch. The mixture is heated at or near 100° C. until the starch is gelatinised, and the jelly formed is treated with a base capable of liberating the starch-coagulating base in order to effect a smooth and uniform coagulation of the starchy material.—J. H. L.

XVI.—SOILS; FERTILISERS.

Bacterial activities of the soil; Influence of moisture on the ——. J. E. Greaves and E. G. Carter. Soil Sci., 1920, 10, 361—387.

THE soils used, 22 in number, ranged from a loose sand to a very stiff clay, and their content of organic matter varied considerably. In every case maximum ammonification occurred when the soil contained 60% of its water-holding capacity of water. Nitrification was at its maximum at 50—60% of water, but the results for nitrogen fixation were not so uniform, two maxima being shown by many soils, one at 50—60% and the other at 70—80% of water as compared with the water-holding capacity. Equations are given showing the relationships between the water requirements for maximum bacterial activity and the moisture equivalent, and wilting and hygroscopic coefficients as defined by Briggs (U.S. Dept. Agric., Bureau Soils Bull. 45, 1907, and Bureau Plant Ind. Bull. 230, 1912).—W. G.

Nodule production [in legumes]; Relation of nitrates to ——. W. H. Strowd. Soil Sci., 1920, 10, 343—356.

WHEN soya beans are grown in sand or soil plentifully supplied with nitrates, there is a marked accumulation of nitrates in the plant, the concentration of nitrate in the plant sap being much greater than in the soil solution. Nitrates retard, and in sufficient quantities entirely prevent, nodule formation. There is evidence that the failure of nodule production in the presence of nitrates in the soil is due, at least in part, to the effect of the high concentration of nitrate in the plant sap on

the growth and reproduction of the nodule bacteria, *Rhizobium leguminosarum*. The amount of reducing sugars in plants decreases with the increase in nitrate, but these sugars were never found to be entirely absent.—W. G.

Nitrites and nitrates in plant tissue; Determination of ——. W. H. Strowd. Soil Sci., 1920, **10**, 333—342.

THE plant tissue is extracted with cold water, and the extract divided into two portions. One portion is made alkaline with sodium hydroxide and distilled with Devarda's alloy (Cu 50, Al 45, Zn 5%). The total nitrogen present as nitrite and nitrate passes over as ammonia and is estimated. The second portion of the extract is heated in a water-bath with excess of aspartic acid for 1 hr. The nitrite is thereby destroyed and the residual nitrate is then estimated as before by distillation with Devarda's alloy.—W. G.

Magnesia as a fertiliser; Use of ——. A. Jacob. Z. angew. Chem., 1920, **33**, 292.

POTATOES were grown on soil which had been manured with nitrogenous and phosphatic fertilisers free from potassium salts, and also on the same soil similarly treated, but with the addition of potassium or magnesium salts, or both. The highest yields of potatoes and also of starch were obtained by the use of a mixture of magnesium and potassium sulphates, whilst a mixture of potassium chloride and kieserite was only slightly less effective. Sandy or peat soils were improved by the addition of magnesium sulphate.—C. A. M.

Nitrolim; Heat changes in the formation of ——. P. Dolch. Z. Elektrochem., 1920, **26**, 455—459.

THE reaction $CaC_2+N_2=CaCN_2+C$ is accompanied by a heat evolution of 58,700 Cals. per mol. of carbide. (*Cf.* J.C.S., Jan., 1921.)—J. F. S.

Potassium; Volumetric estimation of ——, *and its application to the analysis of fertilisers.* G. Ajon. Giorn. Chim. Ind. Appl., 1920, **2**, 422—426.

25 c.c. of a 2% potassium chloride or sulphate solution, equivalent to 1·26 or 1·08% K_2O, is made up to 150—200 c.c. in an Erlenmeyer flask, the liquid being then treated, slowly and with stirring, with 50 c.c. of 2*N* tartaric acid solution and 25 c.c. of *N*/2 sodium hydroxide solution. The flask is shaken for 5 mins., 25 c.c. of 96% alcohol being added gradually during the shaking. After standing for 6—8 hrs., the clear liquid is filtered through a 9 cm. barium sulphate filter paper and the precipitate washed 9 times by decantation with neutral 96% alcohol. The filter paper is removed from the funnel, used to detach any particles of precipitate from the rod, and then introduced into the precipitation vessel. A *N*/10 solution of sodium hydroxide in 96% alcohol is added until the contents of the vessel become alkaline to phenolphthalein. The pink colour of the liquid should not disappear within 5 mins., at the end of which time the precipitate is dissolved in aqueous *N*/10 sodium hydroxide solution, the excess of which is determined by titration with *N*/10 hydrochloric acid. Multiplication by 0·00471 of the number of c.c. of sodium hydroxide required to dissolve the bitartrate gives directly the amount of K_2O present. With commercial potassium chloride and sulphate this method gives good results.—T. H. P.

PATENT.

Peat; Treatment of —— *and the production of a preparation for use in horticulture and agriculture.* The Molassine Co., Ltd., and H. C. S. de Whalley. E.P. 152,779, 22.7.19.

CALCIUM cyanamide, 50, is mixed with finely divided peat. 1000, and to the mixture is added calcium carbonate, 50—200 kilos. Potassium chloride, potassium sulphate, sodium sulphate, etc., may also be added. The preparation is ready for immediate incorporation with the soil.—W. P. S.

XVII.—SUGARS; STARCHES; GUMS.

Clarification of cane juice without chemical treatment. F. W. Zerban. La. Bull., No. 173, 1920. Int. Sugar J., 1920, **22**, 643—646, 699—702.

ADSORPTION appears to be the principal factor in all the processes of clarification at present in use in sugar manufacture. Laboratory and factory experiments have proved that efficient clarification may be effected by the use of suitable adsorbing substances, such as kieselguhr, followed by a powerful decolorising carbon (as "Norit"). Using only 0·5 and·1% respectively of these substances, it was found that a sugar greatly superior in quality, and at least as high in yield, compared with that obtained in sulphitation, can be made, a molasses of higher market value than that produced by the usual plantation methods being obtained at the same time.—J. P. O.

Settling of precipitates (aluminium hydroxide and precipitates in limed and heated cane juice). N. Deerr. Int. Sugar J., 1920, **22**, 618—624.

A SUSPENSION containing 0·1—0·5 g. of aluminium hydroxide per 100 c.c. of water when poured into a tall tube becomes resolved after about 3 min. into five zones. The first (uppermost) is quite clear, and the second is characterised by the presence of "stragglers" (particles not less than average size, which have become detached from the main body of the precipitate). The fifth (and lowest) zone is gradually being built up by the particles completing sedimentation. The fourth zone contains the main body of the precipitate, and in this zone the particles, in addition to their vertical movement, have an oscillatory or gyratory motion. The third zone contains particles that have no gyratory motion, and seem to remain unchanged until the time that the fourth zone has disappeared and the third and fifth zones meet, when after an interval the level between the clear liquid and the precipitate becomes sharp and flat, which point is termed the "critical position." That phase of settling which obtains before the critical position is reached is called the "phase of free fall," and that coming after it the "phase of restricted fall." Measurements were made of the rate of settling of suspensions of aluminium hydroxide of varying concentration in columns of liquid of different height. Cane juice which has been limed and heated gives a precipitate which subsides in a similar manner; though the variation in the quality of the juice and the quantity of lime added are factors which also affect the rate of settling. In the case of a juice having an acidity equal to 1·75 c.c. of *N*/1 acid per 100 c.c. (using phenolphthalein), 0·50 and 0·75 c.c. of *N*/1 lime suspension resulted in underliming, while 1·25 and 1·50 c.c. gave effects typical of satisfactory defecation. Inspection of the tabulated results shows a distinct connexion between the amount of lime used and both the rate of settling and the ultimate volume occupied by the mud, the former decreasing and the latter increasing as the quantity of lime is increased. Taking the quantity of lime corresponding to 1·5 c.c. of *N*/1 lime suspension per 100 c.c. of juice (*i.e.*, 0·042 g. per 100 c.c.) as representative of good practice, the conclusion is that the defecation precipitate settles at a uniform rate of 7 cm. per min.; that the critical position occurs at 0·75 of the height of the settling tank; and that the ultimate volume of the mud is about 15% of the volume of the juice. —J. P. O.

[Sugar] boiling scheme used in Java. G. E. G. von Stietz. La. Planter, 1920, **65**, 92—93.

GOOD results are stated to be obtained by boiling three strikes, as follows: (1) Evaporator syrup mixed with second and third strike sugars, the purity being 85°—90°; (2) some of the molasses from the first strike, the purity being 70°—75°; (3) molasses from the second strike, together with the rest of the molasses from the first strike, the purity being 60°. Advantages of this method are that all the merchantable sugar originates from the first strike, giving a good and regular quality; and that in this first strike boiling is particularly easy, since it is not necessary to granulate, but only to evaporate the mixture of syrup and molasses sugar to a sufficient degree, and take in more syrup until the pan is full and until the massecuite can be transferred to the crystallisers. A waste molasses of 30°—32° is finally obtained.—J. P. O.

PATENTS.

Sugar; Apparatus for the manufacture of ——. *[Clarification of juices.]* E. G. Aizcorve. U.S.P. 1,358,132, 9.11.20. Appl., 5.1.18.

THE apparatus comprises a heating tank, a horizontal channel, one end of which is connected with the top of the tank and the bottom of which slopes upwards towards the tank, an inlet pipe for cool juice at the other end of the channel and above the level of the tank, an outlet pipe from the tank, and a discharge opening at the end of the channel remote from the tank.—J. H. L.

Sugar juices; Process for treating crude ——. C. Ebero. G.P. 325,220, 18.11.17.

THE juice is atomised in a current of dry air, the dried product again dissolved, the solution dialysed, and the dialysed portion and residue both again reduced to powder by drying as before. Owing to the moderate heating and rapidity of drying, both the sugar and non-sugar constituents are recovered practically unchanged.—E. H. R.

Vegetable glue. U.S.P. 1,357,310. *See* XV.

XVIII.—FERMENTATION INDUSTRIES.

Barley; Harvesting, storage and drying of ——. A. Cluss, W. Kluger, and V. Koudelka. Z. ges. Brauw., 1920, **43**, 353—358, 361—367.

DIFFERENT portions of the same crop of Original Hannchen barley were, after harvest, treated differently in respect of time of threshing, storage, and drying, and the effects of the various treatments on the grain were investigated. It is concluded that artificial drying of the grain is a valuable means of improving its quality for agricultural and brewing purposes; in particular the germinating power of the grain is markedly increased. The barley should be stored, preferably in the ear, for about 6 weeks before being dried, to permit after-ripening. Better results were obtained by reducing the moisture content from 17·9% to 11·8% than by reducing it only to 13·8%. After storage for about 2 months (in the air) the variously treated lots of grain attained practically the same moisture content, and underwent no further perceptible change in composition.—J. H. L.

Yeast cell; Physiology of the ——. E. Köhler. Biochem. Zeits., 1920, **111**, 17—30.

YEAST previously washed with water contains an activated enzyme which produces fermentation in sugar solution. If this enzyme is not re-activated in the process of fermentation, the fermentation comes to an end; or if the rate of re-activation is slower than the rate of utilisation of the enzyme, the rate of fermentation diminishes. The latter was found to be the case in the author's experiments. The relation of fermentation to the growth of the yeast as well as the localisation of the fermenting enzyme in the cell are discussed.
—S. S. Z.

Enzymes; Action of —— *under abnormal conditions and the alleged aldehyde character of enzymes.* E. Rona. Biochem. Zeits., 1920, **109**, 279—289.

THE activity of pepsin, trypsin, amylase, emulsin, invertase, and maltase was investigated in the presence of well-known carbonyl reagents in order to ascertain whether enzymes possess an aldehyde character. The results obtained show that providing that the suitable hydrogen ion concentration is insured, those enzymes generally exert their action in the presence of the reagents.—S. S. Z.

Acetone production by Bacillus acetoethylicum; Factors that influence ——. C. F. Arzberger, W. H. Peterson, and E. B. Fred. J. Biol. Chem., 1920, **44**, 465—479.

THE chief factor of importance appears to be the reaction of the medium, which for maximum acetone production should be about $p_H = 5·8—6·0$. The production of volatile acids increases when the yield of alcohol and acetone falls, and *vice versâ*. (*Cf.* J.C.S., Jan., 1921.)—J. C. D.

Cellulose; Fermentation of ——. G. J. Fowler and G. V. Joshi. J. Indian Inst. Sci., 1920, **3**, 39—60.

THE conditions favourable for the most rapid formation of the largest possible quantities of methane and hydrogen by the anaërobic fermentation of cellulose were studied with the object of making economic use of this form of potential fuel occurring in the form of waste paper and vegetable débris. The ferment employed was used in the form of a "bacterial emulsion" prepared from the sludge taken from the bottom of the septic tank of a sewage works. Normal celluloses were found to be most resistant, cellulose from lignified fibres were more readily, and hemicelluloses such as banana skins or plantain skins most readily attacked. Schweitzer's reagent can be employed as a rapid test of the suitability of a cellulose material for fermentation. The efficiency and speed of the fermentation is a maximum only at a temperature near the optimum (35° C.), with a certain ratio of cellulose material and inoculant, and if the acid products of the fermentation are kept below 1% by fractional displacement of the liquor from time to time. By gradually "building up" the bacterial emulsion a daily volume of combustible gas equal to 80% of the volume of the fermenting material can be obtained with hemicelluloses. Small quantities of lead, copper, and zinc salts inhibit the fermentation. The gaseous products of the fermentation contain 80—85% of methane and have a calorific value about 1·45 times that of coal gas. The only soluble by-product that could be detected in the hemicellulose fermentation was acetic acid. It is suggested that the fermentation of cellulose waste products might probably be used as an economic source of power in such places as the western coast of India where coal is scarce.—G. F. M.

Mahua flower; Bio-chemistry of the ——. G. J. Fowler, J. D. E. Behram, S. N. Bhate, K. H. Hassan, S. Mahdihassan, and N. N. Inuganti. J. Indian Inst. Sci., 1920, **3**, 81—118.

CHEMICAL and fermentation studies were made of the sugars in the mahua flower (*Bassia longifolia* and *B. latifolia*) with a view to its utilisation as a

source of industrial alcohol. Dextrose, lævulose, maltose, sucrose, pentoses, and cellulose were identified, the total sugar being greatest when the flowers are ready to fall, at which stage it amounts in general to 60—70%. In the growing stages lævulose is present in greater amount than dextrose, but in the final stages the quantities approximate but do not become equal. Sucrose increases in amount up to the shedding of the corolla, but after this and during storage it decreases relatively to invert sugar. Numerous enzymes were detected at various stages of growth of the flower; maltase, catalase, and oxidase were present throughout. Yields of alcohol up to 90% of the theoretical were obtained by fermentation of a mash of the flowers with cultures of the natural yeast occurring in the flower, with the addition of such reagents as sulphuric acid and ammonium phosphate. By increased care in the cultivation, collection, and storage of the flowers a greater yield per tree, and a greater percentage of total sugar, and particularly of sucrose, should be possible of attainment.
—G. F. M.

Methyl alcohol; Detection of —— in liqueurs and spirits. L. Hoton. Ann. Falsif., 1920, **13**, 490—491.

Two hundred and fifty c.c. of the liqueur, containing at least 20% (by vol.) of alcohol, is fractionally distilled, using an efficient fractionating column, at such a rate that 10 drops of distillate per minute are collected. During the first half-minute or so the b. pt. is always low, even with pure ethyl alcohol, but rapidly reaches a value which remains constant during the first 10 mins. In the case of 25% ethyl alcohol the b. pt. during the first 10 mins. is 78° C., and is lowered by several degrees when a small quantity of methyl alcohol is present.—W. P. S.

XIXA.—FOODS.

Milk preserved with bichromate; Composition and analysis of ——. G. Hinard. Ann. Falsif., 1920, **13**, 463—474.

The addition of bichromate (0·1%) to milk retards the development of the bacteria present, but does not destroy them. For a short time the results obtained on the analysis of a bichromated milk are comparable with those yielded by the fresh milk, but decomposition soon commences and affects the constituents to varying and different extents, so that it is not possible to correct the results obtained in order to ascertain the composition of the original milk. Further, the presence of the bichromate itself affects the determination of the total solids to an extent which varies with different milks.
—W. P. S.

Milks; A deficiency in heat-treated ——. A. L. Daniels and R. Loughlin. J. Biol. Chem., 1920, **44**, 381—397.

A thorough investigation of this subject shows that the well-known fact that the calcium salts are rendered insoluble on the prolonged heating of milk is responsible for the lowered nutritive value of such products. The vitamins and the food value of the proteins are apparently unimpaired.
—J. C. D.

Bread and pastry; Leavening of ——. J. Grossfeld. Chem.-Zeit., 1920, **44**, 889—890.

The characteristic and pleasant taste imparted to bread etc. by yeast may be imitated by using sour milk and a mixture of sodium bicarbonate and calcium carbonate as the leavening agent. The acidity of the milk should be about "30 degrees," equivalent to 0·67% of lactic acid; each litre of such milk used in the dough requires 14 g. of a mixture of equal weights of sodium bicarbonate and calcium carbonate.—W. P. S.

Bread; Colloid chemistry of ——. H. Lüers and Wo. Ostwald. Kolloid Zeits., 1920, **27**, 34—37.

A comparison of the results of the authors (J., 1920, 499 A) with those of Upson and Calvin (J., 1915, 629) and Wood and Hardy (J., 1909, 378).
—J. F. S.

Fats; Chemical properties of nutritive —— of various biological values. S. Rosenbaum. Biochem. Zeits., 1920, **109**, 271—278.

No qualitative chemical differences could be established in yolk fat, cod liver oil, butter fat, fat from human milk, lard, and hazel nut oil as regards their sterol and phosphatide contents. It is therefore assumed that the biological differences of these fats are not due to differences existing in their unsaponifiable residues.—S. S. Z.

Vitamin; Effects of water-soluble B —— on nutrition. W. G. Karr. J. Biol. Chem., 1920, **44**, 255—276.

A deficiency of this vitamin in the diet of the dog induces a similar type of pathological condition to that which has been observed in other species. Drying vitamin preparations at 100° C. does not appear to lower their value, but destruction occurs when they are autoclaved at 120° C. for 3 to 4 hrs.
—J. C. D.

Vitamin; Test for anti-beri-beri —— and its practical application. C. Funk and H. E. Dubin. J. Biol. Chem., 1920, **44**, 487—498.

The increased growth of yeast in the presence of extracts containing the B vitamin is utilised as the basis of a method for testing substances for the presence of the vitamin.—J. C. D.

Vitamins; Quantitative method for determination of —— in glandular and other tissues. F. K. Swoboda. J. Biol. Chem., 1920, **44**, 531—551.

A modification of the method of Williams (J. Biol. Chem., 1919, 38, 465; *cf.* J., 1920, 259) is described and also its application to the investigation of the vitamin content of tissues. (*Cf.* J.C.S., Jan., 1921.)—J. C. D.

Feeding cakes contaminated with castor oil seeds. Detection of the latter. C. Brioux and M. Guerbet. Ann. Falsif., 1920, **13**, 150—160.

The presence of castor oil seeds in feeding cakes (a dangerous contamination, since as little as 1—2% has a poisonous effect on animals) may be detected

by extracting the powdered cake several times with boiling 2% potassium hydroxide solution and examining the insoluble residue, especially the black or dark-coloured particles, under the microscope. The castor oil seed husk has a characteristic appearance. The blood-coagulating principle, ricin, present in the seeds may be separated by mixing 30 g. of the powdered cake with 150 c.c. of 0·9% sodium chloride solution and 5 c.c. of xylene, filtering the mixture after some hours, heating the filtrate at 70° C. for 1 hr., and again filtering. The filtrate is then saturated with ammonium sulphate, the precipitate formed collected, washed with 20 drops of water, dissolved in 0·9% sodium chloride solution at 37° C., and the solution filtered. The coagulating effect of the solution on defibrinated blood is then determined. Distinct coagulation occurs within 10 mins. if the cake contains as little as 2% of castor oil seeds.—W. P. S.

Inositol-phosphoric acid of plants; Composition of ——. R. J. Anderson. J. Biol. Chem., 1920, **44**, 429—438.

THE composition of the salts of the organic phosphorus compound from wheat bran corresponds to the calculated composition of salts of inositol-hexaphosphoric acid, $C_6H_6O_6[PO(OH)_2]_6$. (*Cf.* J.C.S., Jan., 1921.)—J. C. D.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Laudanine; Constitution of ——. E. Späth. Monatsh. Chem., 1920, **41**, 297—304.

IT has been shown that laudanine yields metahemipinic acid on oxidation, so that the two hydroxyl groups of the isoquinoline part of the molecule are methylated and the free hydroxyl group must be attached to the benzyl residue. The author finds that ethyllaudanine, in which the phenolic hydroxyl group is protected and masked by an ethyl group, yields 4-methoxy-3-ethoxybenzoic (ethylisovanillic) acid on oxidation; similarly carbethoxylaudanine, in which the hydroxyl of laudanine is replaced by a carbethoxy group, gives carbethoxyisovanillic acid. It follows that the phenolic hydroxyl of laudanine occupies position 3 of the benzyl residue. (*Cf.* J.C.S., Jan., 1921.)—T. H. P.

Sinapin; Synthesis of ——. E. Späth. Monatsh. Chem., 1920, **41**, 271—285.

THE author has succeeded in preparing synthetically a compound of the constitution proposed by Gadamer for sinapin (Arch. Pharm., 1897, **235**, 93) and finds it to be identical with the latter. Various new derivatives of sinapin are described. (*Cf.* J.C.S., Jan., 1921.)—T. H. P.

Atractylin; Tests for the decomposition products of ——. A. Pitini. Arch. Farm. Sperim., 1920, **29**, 88—96. Chem. Zentr., 1920, **91**, IV., 614.

ATRACTYLIN, $C_{30}H_{52}K_2S_2O_{18}$, the poisonous glucoside of *Atractylus gummifera*, is decomposed by 10% KOH into sulphuric acid, valeric acid, carbohydrate, and an unknown substance A, which is non-poisonous to dogs and does not give Lefranc's characteristic reaction (violet colour with concentrated sulphuric acid). Consequently, in cases of poisoning with this plant, the glucoside can only be detected in the intestines in the unaltered state. The substance A, however, gives a positive reaction in presence of dextrose. Traces of A or of atractylin give with concentrated sulphuric acid containing formaldehyde a red colour which on addition of water changes to an intense blue. A sulphuric acid solution of A gives with vanilin an intense carmine-red colour. The decomposition of atractylin in the animal organism proceeds in the same way as in alkaline solution *in vitro*.—E. H. R.

Ephedrine, pseudo-ephedrine, their optical antipodes and racemic compounds; Syntheses of ——. E. Späth and R. Göhring. Monatsh. Chem., 1920, **41**, 319—338.

THE authors have succeeded, by means of a series of reactions, in synthesising *d*- and *l*-ephedrine and *d*- and *l*-ψ-ephedrine, which have the constitution, $HO.CH(C_6H_5).CH(CH_3).NH.CH_3$, and are stereoisomeric. The *l*-ephedrine thus obtained is identical with natural ephedrine, and the *d*-ψ-ephedrine with natural ψ-ephedrine. It is probable, but has not yet been definitely established, that in ψ-ephedrine the hydroxyl and methylamino groups stand near to, and in ephedrine distant from, one another. (*Cf.* J.C.S., Jan., 1921.)—T. H. P.

Ursone and its distribution in the plant world. A. M. Nooyen. Pharm. Weekblad, 1920, **57**, 1128—1142.

URSONE is a general constituent of the *Ericaceæ* and is also found in some varieties of *Ilex*. It is best extracted by dilute alcoholic potash and isolated by acidification and recrystallising from hot alcohol. The molecular weight of ursone is 456, corresponding to the formula $(C_{10}H_{16}O)_3$. The potassium and sodium salts form white needles, readily soluble in alcohol. Ursone contains no aldehyde, ketone, or hydroxyl groups, forms no addition products, and is not affected by acid or alkaline permanganate. A nitro-product melting at 210° C. was obtained. The formula $C_{29}H_{47}O.COOH,2H_2O$ is given. The substance and its derivatives are optically active, the potassium salt having $[\alpha]^{15}_D$ = +58°. (*Cf.* J.C.S., Jan., 1921.)—S. I. L.

Botanical chemical notes. E. O. von Lippmann. Ber., 1920, **53**, 2069—2077.

THE formation of calcium malonate has been observed during the fermentation of a sugar solution

which was allowed to cool in a sugar refinery in consequence of cessation of work and to which a considerable quantity of clear lime water had been added. Chelidonic acid has been identified in the leaves of a species of lily termed *Gloriosa superba*, indigenous to Java. Under certain climatic conditions coumarin is found in *Mélilotus arvensis* grown in Central Germany; it probably exists as a glucoside which is hydrolysed by an enzyme present in the plant and also by emulsin. A clear viscous gum found in a hole in the trunk of a mountain ash which had been struck by lightning, was found to pass rapidly into a resin (sorban) which is hydrolysed to sorbinose by the conjoint action of the fresh sap of the leaves and twigs of the mountain ash but not by the juices acting singly. Melibiose has been isolated from a clear, almost colourless syrup which, on an unusually warm day, had exuded from an incision in the stem of the mallow.—H. W.

Aminohydroxyphenylarsenoxide; Detection of —— in diaminodihydroxyarsenobenzene hydrochloride (salvarsan). H. Cousin. J. Pharm. Chim., 1920, **22**, 390—392.

One g. of the sample is dissolved in 10 c.c. of methyl alcohol, the solution is diluted with 80 c.c. of water, 1·5 g. of calcium carbonate is added, and the mixture is shaken. The hydrochloride is decomposed and the diaminodihydroxyarsenobenzene is precipitated completely; the mixture is diluted to 100 c.c., filtered, 50 c.c. of the filtrate is diluted with 75 c.c. of water, 5 c.c. of $N/1$ hydrochloric acid is added, and the aminohydroxyphenylarsenoxide is titrated with $N/20$ iodine solution.—W. P. S.

Tartaric acid from tamarinds. J. J. Sudborough and P. N. Vridhachalam. J. Indian Inst. Sci., 1920, **3**, 61—80.

Tamarind pulp contains about 12—14% of tartaric acid, part of which is in the free state and part as potassium bitartrate, and the possibility of the commercial utilisation of tamarinds in India as a source of this acid is suggested. The acid can easily be recovered by the methods used in the production of tartaric acid from wine lees, provided the pulp is first heated for 1 hr. at 160° C. in an autoclave in order to render the expressed liquor capable of being readily filtered. The yields of pure recrystallised acid obtained on a technical experimental scale amounted to about 6% on the weight of the pulp, and, in addition, about 1·7% as pure potassium bitartrate. A certain amount can also be recovered from the final mother liquors as calcium tartrate.—G. F. M.

Lactic acid; Technique of the determination of ——. G. Riesenfeld. Biochem. Zeits., 1920, **109**, 247—270.

The extraction of lactic acid with amyl alcohol according to Ohlson's method (J., 1916, 1182) yields satisfactory results when aqueous solutions are employed but not when the solutions contain protein. In such cases the author therefore recommends the precipitation of the protein with phosphotungstic acid. When the solutions are boiled a small and negligible quantity of the lactic acid is retained by the coagulum.—S. S. Z.

Acetic anhydride; Method for estimating the strength of ——. K. Wolgast. Svensk Kem. Tidskr., 1920, **32**, 110. Chem. Zentr., 1920, **91**, IV., 597.

Exactly 25 c.c. of water is added to a solution of 25 c.c. of acetic anhydride in 20 c.c. of benzene, the mixture is shaken for 15 secs., allowed to settle, and the volume of the aqueous layer is measured in a burette. The acetic anhydride remains in solution in the benzene, whereas the acetic acid is extracted by the water, and thus the increase in volume ×4 gives the percentage of acetic acid in the sample. A small correction is necessary on account of the solubility of the anhydride in water.—L. A. C.

Urea; Transformation of ammonia into ——. C. Matignon and M. Fréjacques. Comptes rend., 1920, **171**, 1003—1005.

The equilibrium pressure, p, in atmospheres, for ammonium carbonate heated at different temperatures in an enclosed space such that the volume occupied by the gaseous phase is as small as possible, is given by $\log p = -1511/T + 5{\cdot}6 \log T - 9{\cdot}4$.—W. G.

Acetone and aldehyde; Determination of —— in the same solution. W. Stepp and W. Engelhardt. Biochem. Zeits., 1920, **111**, 8—17.

Ripper's method (J., 1901, 288) was found to be suitable for the estimation of acetone and aldehyde in mixtures providing that at least 40 hrs. is allowed for the reaction to take place. Results obtained in the estimation of acetone and aldehyde in mixtures by the iodoform method were unsatisfactory.—S. S. Z.

Acetone, acetaldehyde, and formaldehyde; Differential analysis of —— in organic liquids. E. Pittarelli. Arch. Farm. Sperim., 1920, **29**, 70—80, 81—87. Chem. Zentr., 1920, **91**, IV., 616—617.

A large number of reactions of acetone, acetaldehyde, and formaldehyde are given. If to the solution under examination crystals of hydrazine sulphate or hydrochloride are added, then methyl orange followed by hydrochloric acid and mercuric iodide, after a few minutes a carmine-red precipitate appears if formaldehyde is present. This reaction is not given by acetone or acetaldehyde. With carbazole in alcoholic solution formaldehyde gives a green coloration in presence of concentrated sulphuric acid, not given by acetone or acetaldehyde. The aldehydes react with neutral hydrazine salts with liberation of free mineral acids, whilst acetone only gives this reaction with hydroxylamine salts. This difference can be utilised as a qualitative and quantitative test for acetone in presence of formaldehyde and acetaldehyde. Neutral colourless solutions of rosolic or brazilinic acid in sodium sulphite are coloured violet by aldehydes and acetone, through liberation of free alkali. This reaction is most sensitive with formaldehyde, least with acetone. Acetone and acetaldehyde give with hypobromite and phenols colour reactions not given by formaldehyde. They can also be identified by the isonitrile reaction or by reduction to acetylene after conversion by bromine into bromoform. Acetone is better estimated by the hydroxylamine method (titration of mineral acid liberated from a hydroxylamine salt) than by the iodoform process. A method is given for estimating free and combined acetone in urine. —E. H. R.

Carbon; Water-soluble colloids from artificial varieties of ——. K. A. Hofmann and W. Freyer. Ber., 1920, **53**, 2078—2095.

Colloidal preparations of an acid character have been obtained by oxidising certain kinds of carbon with potassium chlorate and hydrochloric acid. Lampblack or sawdust charcoal prepared at a low temperature was most suitable. The products were partly water-soluble, precipitated by acids; partly soluble only in dilute alkalis. The water-soluble substances were the higher oxidation products. The water-soluble product from lampblack was a monobasic acid, $C_{11}H_3O_4$, forming a soluble ammonium salt and an insoluble barium salt, whilst the alkali-soluble product had the composition $C_{11}HO_3$. The water-soluble product from charcoal had the composition $C_{14}H_7O_8$; and the alkali-soluble product was a dibasic acid, $C_{14}H_7O_7$, forming a soluble ammonium and insoluble barium and calcium salts. The products are black to brownish-black in colour,

forming intensely coloured solutions. The colloidal particles in solution are of dimensions of the order $2-4\times10^{-6}$ cm. and show well-marked Brownian movements. The products are suitable for pharmaceutical use. They powerfully adsorb iodine, some dyestuffs, and bacteria. When shaken with an alkaline solution of silver nitrate, under the influence of light, colloidal silver is adsorbed by the colloid. (*Cf.* J.C.S., Jan., 1921).—E. H. R.

Colloidal metal solutions; Influence of —— on lower organisms and the reason of their influence. O. von Plotho. Biochem. Zeits., 1920, **110**, 1—32.

THE behaviour of bacteria, algæ, moulds, higher plants, and lower animals in metal hydrosols was investigated. A decided storage of gold was observed in the case of moulds kept in colloidal gold solutions. This entrance of the gold into the organisms was observed to be more regular and intensive in the living organisms than in the dead moulds. The storage takes place in the membrane and the gold is deposited there without entering into combination with the tissue.—S. S. Z.

Colloidal metal solutions; Influence of —— on mycelia transferred from different nutrient media. O. von Plotho. Biochem. Zeits., 1920, **110**, 33—59.

THE fixation of metallic colloids by moulds depends on the amount of protective organic colloids present. Fully protected metallic sols are not fixed at all. The storage takes place only in acid, not in alkaline media. This is explained by the fact that the fixation of the metallic colloids is a condensation process brought about by the neutralisation of the electric charge of the metallic particles by that of the particles of the hydrogel of the membrane of the moulds where the metal is fixed. The charge of the gold particles in negative; that of the particles of the hydrogels depends on the reaction of the medium. The growth of the moulds was not inhibited by gold sols, but was so by colloidal silver and copper solutions.—S. S. Z.

Separator for use in essential oil distillation; Automatic ——. H. E. Watson. J. Indian Inst. Sci., 1920, **3**, 15—18.

AN automatic separator for immiscible liquids, adapted particularly to the separation of essential oils from aqueous distillates, consists of a cylindrical vessel provided with a float kept in a vertical position by means of a stem which passes through a hole in the centre of the cover of the vessel and terminates at the bottom in a conical needle valve forming the outlet for the heavier liquid. The float is weighted to take up a position of equilibrium at the surface separating the two liquids, and the distillate is introduced horizontally into the vessel at about this point. A rise in the level of the heavier liquid lifts the float and opens the needle valve, thus allowing a discharge of the liquid until the level has again fallen to the normal position. The lighter liquid collects in the upper part of the vessel until it reaches the level of a discharge pipe, through which it continuously flows off at a rate proportional to the inflow of the distillate. A separator of this type about 8 in. in diam. and 10 in. deep is capable of dealing with about 100 lb. of distillate per hr.—G. F. M.

PATENTS.

Chlorhydrins and bromhydrins; Process and apparatus for the manufacture of ——. Commercial Research Co., Assees. of B. E. Eldred and B. T. Brooks. E.P. 126,311, 2.5.19. Conv., 3.5.18. (*Cf.* E.P. 128,578; J., 1920, 764 A.)

A GASEOUS olefine or mixture of olefines is brought into intimate contact in the lower part of a vessel or tower with a solution of hypochlorous or hypobromous acid prepared in the upper part of the tower by the action of chlorine or bromine vapour on a solution of a reagent, such as a borate, which is capable of removing the halogen acid produced according to the reversible reaction, $Cl_2+H_2O \rightleftarrows HCl+HOCl$, but which will not appreciably react with the halogen oxyacid. The solution containing the halogenhydrin, together with excess of borate, boric acid, and sodium halide, is drawn off from the base of the tower, cooled to separate the boric acid, and, after re-saturation with borax, is again circulated through the tower. The above process is repeated until a sufficient concentration of halogenhydrin has been produced in the solution, from which it is then isolated either by distillation or extraction with a solvent.—G. F. M.

Acrolein; Process for the stabilisation of ——. C. Moureu, C. Dufraisse, P. Robin, and J. Pougnet. E.P. 141,361, 8.4.20. Conv., 8.4.19.

THE transformation of acrolein into diacryl is checked by the addition of a small proportion of phenolic or polyphenolic substances, such as pyrogallol (0·1%), catechol or quinol (0·2%), gallic acid (0·4%), or tannin (1%). Sunlight and temperatures above 30° C. should be avoided. (*Cf.* J., 1919, 923 A; 1920, 82 A, 173 A.)—D. F. T.

Methane; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 146,110, 21.6.20. Conv., 28.6.19.

A MIXTURE of carbon monoxide and hydrogen is passed through a series of furnaces containing a heated catalyst, the resulting water being removed and more carbon monoxide being introduced as the mixture leaves each furnace. In this way the proportion of hydrogen to carbon monoxide can be maintained in excess of 5:1, which is the limit for the avoidance of the partial decomposition of carbon monoxide into dioxide and free carbon, and yet an almost complete consumption of the hydrogen can be effected.—D. F. T.

Ethylene chloride; Process for the production of ——. T. Goldschmidt A.-G., and O. Matter. E.P. 147,908, 9.7.20. Conv., 22.5.15.

DRY ethylene prepared by passing ethyl alcohol vapour over a contact substance, such as alumina at 400° C., is allowed to react with one-third to one-fourth of its volume of chlorine between 30° and 120° C. in the presence of a catalyst, such as chloride of iron, copper, or antimony; the temperature of the reaction chamber can be adjusted by means of a cooling device. The excess of ethylene is separated by removing the ethylene chloride in a suitable condensing plant.—D. F. T.

Saccharin; Process for the manufacture of ——. Soc. Chim. des Usines du Rhône. E.P. 153,520, 8.3.20. Conv., 24.1.20.

BY treatment with chromic acid or a bichromate, in the presence of sulphuric acid of at least 35% concentration, at a temperature dependent on this concentration, it is possible to oxidise toluene-o-sulphonamide to o-benzoic sulphimide (saccharin). It is advisable to use an excess of the amide so as to utilise the chromic acid completely. —D. F. T.

β-Dialkylamino-ethylaminobenzoic alkyl esters; Manufacture of ——. Soc. Chim. des Usines du Rhône. E.P. 153,827, 2.3.20. Conv., 15.11.19. Addn. to 128,554 (J., 1920, 43 A).

β-DIALKYLAMINO-ETHYL-*p*-AMINOBENZOIC alkyl esters of the general formula, $R_2N.(CH_2)_2.NH.C_6H_4.CO_2R'$, are obtained from β-chloroethyldialkylamines and *p*-aminobenzoic acid esters, by heating the two compounds together in equimolecular proportions, either with or without the use of a neutral diluent. For example, when 1 mol. of β-chloroethyldiethylamine is added to a boiling solution of 1 mol. of ethyl *p*-aminobenzoate in three times its weight of toluene, and the boiling is continued for 1—2 hrs., a solution is obtained which on cooling deposits crystals of ethyl β-diethylamino-ethyl-*p*-aminobenzoate monohydrochloride, m.p. 156° C. The compounds obtained by the interaction of β-chloroethyldiethylamine with the methyl, propyl, normal and iso-butyl, and iso-amyl esters of *p*-aminobenzoic acid are also described.—G. F. M.

Furfural and volatile organic acids; Manufacture of —— from extracted corn [maize] cob pentosan. K. P. Monroe. U.S.P. 1,357,467, 2.11.20. Appl., 8.4.20.

EXTRACTED corn (maize) cob pentosan is boiled with concentrated acid, the mixture distilled, and furfural and volatile organic acids separated from the distillate by fractional distillation. The volatile organic acids are finally neutralised by alkali. —J. S. G. T.

Chlorination process. A. E. Houlehan, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,358,851, 16.11.20. Appl., 26.9.17.

CHLORINE is absorbed in a hydrocarbon liquid in the absence of light, and the liquid is then heated to effect chlorination of the hydrocarbon. —J. S. G. T.

Fatty acid halides and phosphorus oxyhalides; Process of making ——. F. J. Kaufmann, Assr. to C. Ritchie. U.S.P. 1,359,071, 16.11.20. Appl., 27.1.20.

A MIXTURE of the fatty acid and phosphorus trihalide is halogenated at a temperature below 50° C. —D. F. T.

Amylodextrin and calcium fluoride; Manufacture of a colloidal preparation of ——. Lecinwerk E. Laves. G.P. 325,561, 12.3.19. Addn. to 323,783 (J., 1920, 802 A).

A SOLUBLE calcium salt is added to a solution of amylodextrin and a fluoride.—L. A. C.

Esters; Process for obtaining —— from crude pyroligneous acid. Haschkowerke Eberhard & Jakob. G.P. 325,639, 10.4.18.

THE acid is neutralised and evaporated until, on cooling, sodium acetate crystallises out, the methyl alcohol present being recovered. To the further concentrated mother liquor, concentrated crude methyl or other alcohol is added with alkali bisulphate and a flux containing silicic acid, the mixture is allowed to stand and later the ester formed distilled off. The silicious flux serves to prevent superheating during distillation.—E. H. R.

p-Aminophenylarsinic acid; Preparation of a derivative of ——. H. Rupe. G.P. 325,640, 25.11.17.

A PRODUCT which crystallises from alcohol in white needles, m.p. 220° C., and has a powerful action on trypanosomes and spirillæ, is prepared by heating hydroxy- or chloro-methylenecamphor with sodium *p*-aminophenylarsinate.—L. A. C.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plate; Photochemical investigations of the ——. R. E. Slade and G. I. Higson. Roy. Soc. Proc., 1920, A, 98, 154—170.

SINCE it is not generally true that when light acts on a sensitive photographic film, the number of grains rendered developable is a simple function of the exposure, It, it is deduced that the mechanism of the process cannot be the absorption of light in discrete quanta. If P is the probability that any grain is rendered developable by an exposure, It, then $dx/dt=P(a-x)$, where a is the total number of grains and x those rendered developable. In the experimental investigation of the relationship between P and It, plates were specially coated with a film, not more than one grain thick, of an emulsion of grains of uniform size and assumed of uniform speed. The exposed plates were developed and washed but not fixed, and the values of a and x computed by counting; from these was calculated $\log_e a/(a-x)=A$, obtained by integrating the above equation. By varying I, keeping t constant, and plotting A against I, it was found that if I is great and t small, $A=k_1I$, while if I is small and t great, $A=k_2I^2$. Similar relationships between A and t were obtained for exposures with constant intensity. Combining these four relationships it is deduced that $A=k_0I(1-e^{-k_4I})(t-k_5\{1-e^{-k_6t}\})$ which is the equation for the photochemical law of the silver halide grain.—B. V. S.

[Colour-]sensitising properties of a new series of [cyanine] colouring matters. A. and L. Lumière and H. Barbier. Bull. Soc. Franç. Phot., 1920, 7, 182—184.

PARTICULARS are given of the absorption bands and sensitising properties, with spectographs illustrating the latter, of three typical members of the series of dyes previously described by Barbier (J., 1920, 528 A). The spectrograph for Cyanine A, obtained from the ethiodides of dimethylaminoquinoline and toluquinaldine, shows maxima in the blue, yellow, and orange, and a minimum in the blue-green. Cyanine B, from the ethiodides of dimethylaminoquinoline and dimethylaminoquinaldine, shows similar maxima to Cyanine A, the action extending further into the red, and a more strongly marked minimum. Pantochrome, obtained by the condensation of dimethylaminoquinaldine with dimethylaminobenzaldehyde, shows a very uniform sensitiveness nearly up to 700μμ, the minimum in the blue-green being very small.—B. V. S.

Collodion; Light-sensitiveness of ——. B. Homolka. Phot. Korr., 1920, 57, 239—241.

IN the decomposition of nitrocellulose under the action of sunlight, first demonstrated by Gladstone and Hofmann in 1852, nitric acid is formed, and this is a source of danger in some applications of celluloid or collodion. Its formation is easily shown to take place within the time of a normal photographic exposure by the aid of 9-aminophenanthrene, which is converted by very small quantities of nitric acid into the deep red 9.9′ azoxyphenanthrene. Thus a collodion film containing aminophenanthrene, if exposed under a negative, yields a red positive which may be fixed in benzene in which the amino-compound but not the azoxy-compound is soluble. If a plain collodion film be exposed under a negative there is no visible result, but a latent image is formed, as is seen by treating the film with a benzene solution of 9-aminophenanthrene, drying, and then exposing the film under plain glass. A red negative, a copy of the original negative, results.—B. V. S.

[Photographic] plates; Simultaneous development and fixing of ——. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1920, **67**, 747—748.

IN preparing the combined developing and fixing solution, recommended by Otsuki and Sudzuki (J., 1914, 668), containing metoquinone, sodium sulphite, sodium thiosulphate, and caustic soda, it is preferable to use a titrated caustic soda solution owing to the uncertainty of composition of the solid substance. The only other alkali which gave a satisfactory developer and is not open to this objection was tribasic sodium phosphate. Chloranol, prepared by the condensation of 2 mols. of monomethyl-*p*-aminophenol and 1 mol. of chloroquinol, gives similar results to metoquinone.—B. V. S.

Negative [photographic] development in bright light. Lüppo-Cramer. Phot. Ind., 1920, 378—379.

BATHING in an amidol (diaminophenol hydrochloride) solution, 0·02 to 0·05%, for about 1 min. reduces the sensitiveness of a photographic plate from 50 to 100 times and allows subsequent development in a bright yellow light. With most developers there is hardly any effect by this previous treatment; glycin, however, gives dichroic fog, and quinol, by reason of the presence of small quantities of the amidol, becomes an energetic instead of a slow-working developer. Triaminobenzene acts similarly to diaminophenol, but the diaminoresorcinols, triaminophenol, and triaminotoluene do not produce the same effect. The addition of sulphite or bisulphite to the amidol solution reduces its desensitising effect considerably.
—B. V. S.

Cellulose-ester films. U.S.P. 1,357,733. *See* V.

XXII.—EXPLOSIVES; MATCHES.

Nitroso compounds; Detection of —— and determination of aromatic nitro derivatives in smokeless powders. C. Lutri. Giorn. Chim. Ind. Appl., 1920, **2**, 557—559.

α-NAPHTHYLAMINE in 1% acetic acid solution gives an intense violet coloration with nitrous acid, nitroso-amines, and other nitroso derivatives. Certain oxidising agents, such as potassium chlorate, hydrogen peroxide, and lead peroxide also produce a violet coloration with the reagent, but these are not constituents of smokeless powders. No coloration is given by ammonium persulphate, potassium nitrate, or dinitrotoluene. For the estimation of aromatic nitro compounds 3 g. of the finely divided smokeless powder is extracted for about 6 hrs. with ether, the extract evaporated at a low temperature, and the residue heated with 50 c.c. of 20% sulphuric acid on the water bath beneath a reflux condenser, the flask being frequently shaken during 6 hrs. The liquid is filtered, the filtrate extracted with benezene, the extract evaporated at about 50° C. and the nitro derivatives weighed.—C. A. M.

Solenite; Estimation of mineral oil in ——. R. Moretti and M. Taliani. Giorn. Chim. Ind. Appl., 1920, **2**, 433—434.

FIFTY grams of the powdered explosive is boiled for 6 hrs. in a Jena flask under a reflux condenser with 400—500 c.c. of 10% sodium hydroxide. The cooled liquid is extracted several times with ether in a separating funnel, the ethereal solution being separated carefully and completely and filtered into a weighed flask; the ether is removed by distillation and the residual mineral oil dried at 105° C. until of constant weight. Good results are obtained with solenite and ballistite.—T. H. P.

Vapour pressures; Method of measuring low —— with its application to the case of trinitrotoluene. A. W. C. Menzies. J. Amer. Chem. Soc., 1920, **42**, 2218—2221.

A MCLEOD gauge is immersed in a constant temperature bath and connected with a bulb immersed in a second bath. The apparatus is evacuated, nitrogen is admitted up to a low pressure, and the pressure increase on heating the bulb is determined. The material is placed in the bulb, and the operation repeated, vapour being prevented from diffusing to the gauge by cooling a portion of the connecting tube. From the increase of pressure the vapour pressure of the substance may be calculated. The vapour pressures of trinitrotoluene, m.pt. 80·5° C., dried but not specially purified, were calculated to be as follows in mm. mercury at 0° C.:—(80° C., 0·042 mm.); (81°, 0·044); 82°, 0·046; 83°, 0·048; 84°, 0·051; 85°, 0·053; 86°, 0·056; 87°, 0·059; 88°, 0·062; 89°, 0·064; 90°, 0·067; 91°, 0·070; 92°, 0·074; 93°, 0·078; 94°, 0·081; 95°, 0·085; 96°, 0·089; 97°, 0·093; 98°, 0·098; 99°, 0·102; 100°, 0·106; 101°, 0·110; 102° C., 0·116 mm. These values were obtained graphically from observed pressures, 0·046 mm. at 81·6° C., 0·067 mm. at 90·1° C., and 0·120 mm. at 102·6 C.—J. R. P.

Nitro products; Decomposition of ——. S. Brown. Chem. Trade J., 1920, **67**, 673.

IN a laboratory investigation into the cause of an explosion on a nitration plant, it was found that the presence of lubricating oil in a nitration mixture accelerates the rate of decomposition by acid of the nitro product, *e.g.*, dinitrotoluene.—L. A. C.

PATENTS.

Gelatinous nitroglycerin explosives proof against firedamp; Manufacture of ——. Dynamit A.-G. vorm. A. Nobel und Co., and P. Naoum. E.P. 140,746, 12.12.19. Conv., 22.3.19.

GELATINOUS nitroglycerin explosives of a plastic nature, and safe for use in presence of firedamp, are prepared, without the use of amylaceous or similar materials, by adding concentrated solutions of hygroscopic salts, advantageously mixed with a little glycerin, to the explosive constituents. A suitable composition consists of:—Nitroglycerin, 30%; 50% calcium nitrate solution, 3%; glycerin, 1%; ammonium nitrate, 30%; sodium chloride, 35%; woodmeal, 1%. This mixture gives a lead block expansion of 220 cm., and has a *charge limite* of 650 g. It remains unchanged during storage.
—W. J. W.

Amatol; Method and apparatus for removing —— from shells or like explosive bodies for the purpose of recovering ammonium nitrate. C. F. Beakbane and J. W. Arnot. E.P. 153,123, 14.8.19.

A WATER tank provided with a steam coil has an outlet pipe in communication with a centrifugal pump and a supply pipe terminating in nozzles over which are placed the shells to be emptied. Below these nozzles is placed a trough which drains into a settling tank with an overflow outlet into the water tank. A branch pipe from the centrifugal pump passes into another settling tank from which liquid can be conducted into an evaporating tank and crystallising vessels. Water at 86° C. and under a pressure of 25—55 lb. per sq. in. is pumped from the water tank through the nozzles into the shells, from which the mixture of ammonium nitrate solution and trinitrotoluene flows round the nozzles through the trough into the settling tank where sludge is deposited. The solution is returned to the water tank and circulated through the shells until it reaches a density of 50° Tw. (sp. gr. 1·250), after which it is pumped through the branch pipe into the second settling tank where the trinitrotoluene is eventually precipitated. The ammonium

nitrate solution is then run off into the evaporating tank, concentrated to 72° Tw. (sp. gr. 1·360), and then passed into the crystallising pans.—W. J. W.

Ammonium perchlorate explosives. R. M. Cook and E. W. Harris, Assrs. to Atlas Powder Co. U.S.P. 1,357,764, 2.11.20. Appl., 2.9.20.

The composition of the explosives is as follows:—Ammonium perchlorate, of which at least 50% passes a 60-mesh sieve, and coated with 0·1 to 1·5% of vegetable or mineral waxes or oils, 15—65%; manganese dioxide, 3—15%; sodium nitrate, coated with 0·1—1·5% of vegetable or mineral waxes or oils, 5—50%; liquid aromatic nitro-compounds, 0·5—5%; trinitrotoluene, 15—30%; sulphur, 0—7%; chalk, 0—3%. The proportions of the ingredients are selected so as to give an oxygen balance of the explosive between −4% and +6%. —W. J. W.

Nitrocellulose; Process of stabilising —— and product thereof. C. L. Reese, Assr. to The Arlington Co. U.S.P. 1,358,653, 9.11.20. Appl., 8.12.16.

Nitrocellulose or soluble nitrocellulose may be stabilised by the addition of 0·1—2% of dicyanodiamide, with or without a solvent, or camphor, or both.—W. J. W.

Nitration acid from the manufacture of nitrocellulose or the like; Recovery of ——. S. Hamburger. G.P. 299,680, 12.5.16.

After nitration the bulk of the acid is allowed to flow away and the material is washed, without centrifuging, with sulphuric acid of the same strength as the waste acid, so that on mixing the two lots of acid there is no evolution of heat. —L. A. C.

XXIII.—ANALYSIS.

Ultrafiltration apparatus. L. S. Villegas. Contr. Estud, Ciencias [La Plata], Ser. mat. fis., 1919, 2, 415—418. Chem. Zentr., 1920, 91, IV., 614—615.

A glass cylinder, 9 cm. high and 7 cm. diam., is closed at the top and bottom with bronze discs and rubber rings to make a tight joint. In the upper disc are two openings for a manometer and pressure pump respectively. On the bottom, between the rubber ring and bronze disc, is a thin metal disc of platinum, aluminium, or nickel, perforated with a number of holes 1 mm. in diam., to support the ultra-filter. The latter is prepared by completely immersing 12·5 g. of guncotton in absolute alcohol, and adding ether to bring the volume up to 500 c.c. Part of this solution is poured on to a glass plate, and when it has coagulated it is soaked in water, and the thin layer removed from the plate. Such filters are permeable to colloids, the permeability depending on the acidity; 0·5% of acetic acid greatly improves the permeability. Collodion filters were also successfully used, their permeability depending not only on their acidity, but on the time elapsing after the addition of acid. The apparatus is specially useful for colloidal solutions of metals, and has also been used for solutions of hæmoglobin, albumin, and milk.—E. H. R.

Thoulet's solution; Substitute for ——. A. Thiel and L. Stoll. Ber., 1920, 53, 2003.

For the determination of the specific gravity of organic substances by the suspension method, an aqueous solution of lead perchlorate can be used in place of the more expensive Thoulet's solution (mercury-potassium iodide) or Rohrbach's solution (mercury-barium iodide). The perchlorate solution is prepared by saturating commercial perchloric acid with commercial lead carbonate and evaporating to the saturation point. The solution saturated at 15° C. is a mobile liquid, sp. gr. 2·6, and contains 78% of lead perchlorate.—E. H. R.

Cresol red; Salt error of ——. R. C. Wells. J. Amer. Chem. Soc., 1920, 42, 2160—2167.

In the determination of the hydrogen ion concentration of salt water by a colorimetric method with cresol red as indicator, it is necessary to make a correction for the effect of the salt on the colour of the indicator. This correction has been determined with buffer solutions of borax and boric acid without and with sodium chloride, and a table of corrections for use with the indicator is given. —J. R. P.

Alkali metals; Determination of —— as sulphate. N. Schoorl and I. M. Kolthoff. Chem. Weekblad, 1920, 17, 425—427.

Van Duin (*ibid.*, 283) has stated that errors arise in the ignition of alkali pyrosulphate to sulphate, and proposes the evaporation of a solution of ammonium carbonate with the pyrosulphate, and ignition of the residue. It is shown that this introduces even greater errors, and that if a fragment of ammonium carbonate is added to the crucible in which the residue, after careful evaporation of the acid, is maintained at the maximum temperature without melting, volatilisation occurs quietly and evenly, and very accurate results may be obtained. (*Cf.* J.C.S., Jan., 1921.)—S. I. L.

Barium, strontium, and calcium; Detection of —— by the chromate method. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 1080—1084.

The three elements can be satisfactorily detected by the procedure given; 1 mg. of either in presence of 100 mg. of each of the others per l. can be identified. Barium is precipitated by addition of bichromate to a solution containing acetic acid and sodium acetate, strontium from the filtrate by addition of ammonia and alcohol, and calcium by the oxalate method. (*Cf.* J.C.S., Jan., 1921.) —S. I. L.

Lead; Determination of —— as chromate. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 934—941.

The lead is precipitated as chromate, a small quantity of aluminium chloride being added to improve the separation. For small quantities, the precipitate is filtered off, dissolved, after washing, in hydrochloric acid, excess of potassium iodide added, and the liberated iodine estimated by thiosulphate. For larger quantities, the excess of chromate may be estimated in the same manner, since large precipitates of lead chromate are not easily handled. The method is quick and accurate, and may be applied to lead sulphate, which is dissolved in sodium acetate and acetic acid. Where the lead is combined with a strong acid, conductivity determinations may be made, since the chromic acid liberated by the action of potassium bichromate functions as a strong monobasic acid. In this method, the liberated chromic acid is titrated with soda, the conductivity diminishing until all the acid has been converted into bichromate, and then slowly increasing. (*Cf.* J.C.S., Jan., 1921.) —S. I. L.

Electro-analytical practice. Determination of mercury. W. Böttger. Z. Elektrochem., 1920, 26, 445—452.

Mercury is quantitatively deposited from solutions of mercurous nitrate, in the presence of nitric acid, when a constant EMF of 1·4—1·5 volts is employed. From mercuric nitrate solutions to which 1 c.c. of nitric acid (sp. gr. 1·4) has been added, it is deposited quantitatively when the EMF is so regulated that the current remains at 1 ampère. To ensure this the electrolysis is started with an EMF of 1·8 volts, which rises to

3·0 volts in about 4 mins. and finally reaches 3·2—3·3 volts, at which value the electrolysis is completed. Pure alcohol and pure ether may be used for drying the deposit if the electrode is exposed to the air for only a short time (10—15 mins.). When a silvered net electrode is used the loss in the above processes is very constant and amounts to 0·4 mg. Separation from a cyanide solution is accompanied by a loss of 0·6 mg. The accuracy of the cyanide method is somewhat doubtful when a large amount of potassium cyanide is present and when a large current is used.—J. F. S.

VIII.—GLASS; CERAMICS.

Applications.

Banks. Non-steaming glass. 35,603. Dec. 18.

Highfield, Laurie, and Osmosis Co. Mining or concentration of clay. 35,796. Dec. 21.

Complete Specifications Accepted.

19,288 (1919). Tucker and Reeves. Method of getting viscous glass-charges. (131,586.) Dec. 30.

25,284 (1919). Carborundum Co. (Linbarger). Manufacture of grinding wheels from ceramic or refractory materials. (155,076.) Dec. 22.

IX.—BUILDING MATERIALS.

Applications.

Dalhoff and Lunn. Manufacture of material for use in making light concrete. 35,993. Dec. 22.

Graeffe and Haase. Preparing building-material from peat. 35,155. Dec. 14.

Jackson (Bitoslag Paving Co.). Paving mixtures. 36,100. Dec. 23.

Polla. Manufacture of building materials with ligneous fragments. 35,075. Dec. 13. (Switz., 13.12.17.)

Complete Specifications Accepted.

24,757 (1919). McDowall. Fireproof flooring or the like. (155,072.) Dec. 22.

27,648 (1919). Baylor. Slow-setting fat and waterproof cement, and method of producing same. (155,431.) Dec. 30.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Collier. Extraction of metallic compounds from blast-furnace etc. slags. 36,255. Dec. 24.

Collins. Separation and recovery of metals. 35,632. Dec. 18.

Counas. Electric treatment of ores. 35,992. Dec. 22. (Fr., 29.8.19.)

Goskar and Hitch. Manufacture of compositions for case-hardening iron and steel. 36,193. Dec. 24.

Hall, and Rolls-Royce, Ltd. Aluminium-bronze alloys. 35,509 and 36,177. Dec. 17 and 24.

Houmöller. Briquetting cast-iron chips. 35,814. Dec. 21. (Denmark, 19.8.20.)

Hurley. Process of galvanising or zinc-dipping. 36,028. Dec. 23.

Loosli and North. Production of zirconium. 35,326. Dec. 15. (Ger., 14.11.19.)

Complete Specifications Accepted.

19,316 (1919). Madsen. Electro-deposited metals. (142,432.) Dec. 22.

22,370 (1919). Wood, and Minerals Separation, Ltd. Apparatus for the froth flotation process. (155,349.) Dec. 30.

22,959 (1919). Fletcher. Manufacture of puddled iron. (155,042.) Dec. 22.

27,785 (1919). Akt. Ferrolegeringar. Production of chromium or its alloys. (135,187.) Dec. 22.

3279 (1920). Rader, and Akt. Zink. Electric furnaces for producing zinc. (139,160.) Dec. 30.

15,884 (1920). Krupp A.-G. Grusonwerk. Extracting metals from compounds, ores, furnace dust, etc. (144,728.) Dec. 30.

16,559 (1920). McKenna. Purification of ferro-tungsten. (146,108.) Dec. 30.

17,690 (1920). Ayestaran é Irazusta. Conglomeration of pulverulent mineral residues. (155,522.) Dec. 30.

XI.—ELECTRO-CHEMISTRY.

Applications.

British Thomson-Houston Co. (General Electric Co.). Manufacture of resistance material. 35,620. Dec. 18.

Counas. 35,992. *See* X.

Ges. f. Teerverwertung. Manufacture of electrodes of large cross-section. 35,319. Dec. 15. (Ger., 27.11.19.)

Goedicke. Ozone-generating apparatus. 35,633. Dec. 18.

Leitner. Electric accumulators. 35,436. Dec. 16.

Plauson and Vielle. Electrodes and electrolysis. 36,170. Dec. 24. (Ger., 6.7.18.)

Complete Specifications Accepted.

16,907 (1919). Whalley and others. *See* XIII.

24,718 (1919) and 6654 (1920). Oldham and Oldham. Galvanic batteries. (155,071.) Dec. 22.

32,791 (1919). Levin. Electrolytic cells. (155,118.) Dec. 22.

32,794 (1919). Levin. Electrolytic apparatus. (155,457.) Dec. 30.

1840 (1920). Comp. Franç. des Métaux. Electric induction furnaces. (138,604.) Dec. 30.

3217 (1920). Tagliaferri. Electric furnaces. (155,476.) Dec. 30.

3279 (1920). Rader, and Akt. Zink. *See* X.

XII.—FATS; OILS; WAXES.

Applications.

Bigum. Rotary cooling apparatus for fatty substances, emulsions, etc. 35,818. Dec. 21. (Denmark, 22.12.19.)

Böhme A.-G. Production of fat-dissolving substances. 35,723. Dec. 20. (Ger., 19.12.19.)

Chambers and Hammond. Treatment of wool fat etc. 35,591. Dec. 18.

Hey. Removing suspended matter from oils and solutions of oils. 35,382. Dec. 16.

Schou. 35,553. *See* XIX.

Starrels. Production of fatty acids of high melting point. 36,081. Dec. 23. (U.S., 1.3.16.)

Complete Specifications Accepted.

22,080 (1919). Gans. Manufacture of saponaceous cleansing composition. (132,511.) Dec. 22.

22,159 (1919). Vakil. Refining oils and fats. (155,020.) Dec. 22.

3814 (1920). Clayton and Nodder. Cooling apparatus for use in the manufacture of edible fats. (155,477.) Dec. 30.

14,358 (1920). Schoonderwaldt. Preparation of substitutes for linseed oil. (155,508.) Dec. 30.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Complete Specifications Accepted.

16,907 (1919). Whalley, and Micanite and Insulators Co. Recovery of varnish and other ingredients from waste micanite etc. (155,318.) Dec. 30.

22,825 (1919). Arrowsmith. Manufacture of acid pots for use in making white lead. (155,373.) Dec. 30.

23,964 (1919). Schou, and Emulsion Aktieselskabet. Manufacture of painting, priming, and like compositions. (155,398.) Dec. 30.

27,254 (1919). British Thomson-Houston Co. (General Electric Co.). Japans. (155,427.) Dec. 30.

14,358 (1920). Schoonderwaldt. *See* XII.

20,584 (1920). Sudfeldt u. Co. *See* XX.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Applications.

Baines. Rubber mixings. 35,474. Dec. 17.

Roa, Ltd., and Wickham. Apparatus for treating latex. 36,128. Dec. 23.

Complete Specifications Accepted.

1738 (1920). Minton. Rubber-proofed fabrics. (155,469.) Dec. 30.

4240 (1920). Hunter Dry Kiln Co. Treatment of rubber. (138,915.) Dec. 23.

XV.—LEATHER; BONE; HORN; GLUE.

Applications.

Earp. Tanning. 35,099. *See* IX.

Harley. Composition for dressing leather etc. 35,159. Dec. 14.

Complete Specification Accepted.

19,058 (1919). Marris, and Walker and Sons. Treatment of refuse from tanneries etc. (154,961.) Dec. 22.

XVIII.—FERMENTATION INDUSTRIES.

Applications.

Gille, Nathan, and Nathan-Institut A.-G. Cooling and aerating beer wort and separating sludge. 36,263. Dec. 24.

Verein der Spiritus-Fabrikanten. Production of yeast. 35,282—3, 35,285—7, 35,289, 35,290, 35,292—4. Dec. 15. (Ger., 16.3, 24.2, 31.3, 19.3, 15.3, 7.5, 23.12, 12, 15, and 23.4.15.)

Verein der Spiritus-Fabrikanten. Treatment of yeast. 35,284. Dec. 15. (Ger., 26.6.15.)

Verein der Spiritus-Fabrikanten. Production of compressed yeast. 35,288. Dec. 15. (Ger., 19.8.15.)

Verein der Spiritus-Fabrikanten. Treatment of froth of fermenting or boiling liquids. 35,291. Dec. 15. (Ger., 19.8.16.)

XIX.—FOODS; WATER PURIFICATION; SANITATION.

Applications.

Andrews and Paul. Treatment of flour etc. 36,237. Dec. 24.

Quaker Oats Co. Alimentary paste. 35,963. Dec. 22. (U.S., 9.7.20.)

Schou. Manufacture of margarine and edible fats. 35,553. Dec. 17.

Complete Specifications Accepted.

27,285 (1919). Borrowman. Water-softening. (155,092.) Dec. 22.

3814 (1920). Clayton and Nodder. *See* XII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Applications.

Adler. Production of adsorptive charcoal for medicinal purposes. 35,172. Dec. 14. (Czecho-Slov., 5.12.19.)

Fabr. de Prod. Chim. de Thann et de Mulhouse. Manufacture of borneol. 36,260. Dec. 24. (Fr., 28.5.20.)

Spitz. Manufacture of therapeutic preparations of calcium iodide. 36,035. Dec. 23. (Ger., 10.3.16.)

Stockholms Superfosfat-Fabr. Akt. Manufacture of acetaldehyde from acetylene. 35,970. Dec. 22. (Sweden, 16.12.19.)

Complete Specification Accepted.

20,584 (1920). Sufeldt u. Co. Obtaining the salts of sulpho-acids and alkylsulphuric acids from acid resins. (148,579.) Dec. 30.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Applications.

Janzer. Photographic printing. 35,619. Dec. 18.

Kent. Photography. 35,988. Dec. 22.

XXIII.—ANALYSIS.

Application.

Irving and Thorpe. Calorimeters. 35,716. Dec. 20.

I.—GENERAL; PLANT; MACHINERY.

Patents.

Rectifiers for rectifying mixtures of liquefied gases; Process and apparatus for regulating the operations in ——. E. Barbet et Fils et Cie. E.P. 129,648, 9.7.19. Conv., 9.7.18.

The apparatus is provided with devices (pressure, temperature, and speed regulators, meters, etc.) for maintaining regularity of operation, these devices being controlled automatically by the pressure differences existing in the various parts.
—W. E. F. P.

Refrigerating apparatus. C. Delaygue. E.P. 138,938, 13.2.20.

The apparatus is of the type in which cold is produced by the vaporisation of a liquid which has previously been removed (as a gas) from a solvent liquid by boiling or heating and afterwards condensed. A straight pipe of comparatively small diameter leads from the boiler-absorber to the downward sloping portion of the return pipe from the condenser-refrigerator to the boiler-absorber, which latter pipe is continued downwards into the boiler-absorber, ending in a perforated nozzle near the side of the vessel below the liquid level. The condenser-evaporator may be combined in one vessel which takes the form of a jacket surrounding a chamber for the material to be chilled. The jacket should be narrow for the greater part of its height, but very wide for a short distance at the top, to give both a large surface for absorbing heat from the material and a large surface for evaporation of liquid; or the condenser and evaporator may be two separate coils. In this case by means of suitable cocks and valves the main part of the apparatus may be removed, leaving only the evaporating coil attached to the refrigeration chamber.—B. M. V.

Furnaces; Rocking ——. J. Lambot. E.P. 141,054, 31.3.20. Conv., 3.4.19.

A rocking furnace is combined with a recuperator in one structure so that the whole can be tilted, thus avoiding joints between the recuperator and the furnace.—B. M. V.

Kiln. J. Elcock. U.S.P. 1,329,830, 3.2.20. Appl., 8.9.19.

A kiln, circular in plan, is provided with chimneys in the walls spaced regularly around the periphery, and connected by approximately radial passages or slots in the floor with various points in a pair of parallel openings extending across the floor of the kiln near to, but on each side of its centre. Coal is coked in chambers arranged outside the kiln walls, and the coke pushed back into "flash walls" or boxes inside the kiln where it is burnt. The hot gas from these walls circulates downwards in the kiln and passes out through the radial slots in the floor.—W. F. F.

Furnace. C. L. W. Trinks, Assr. to Tate-Jones and Co. U.S.P. 1,360,058, 23.11.20. Appl., 2.2.20.

A furnace comprises a heating chamber provided with a metallic hearth having heat-resisting material immediately underneath. A combustion chamber is situated below the heating chamber.
—J. S. G. T.

Ovens; Device for reversing gaseous currents in [regenerative] ——. E. Lecocq, Assr. to Soc. Gén. de Fours à Coke Systèmes Lecocq. U.S.P. 1,361,595, 7.12.20. Appl., 18.7.17.

The gaseous currents in a regenerative oven may be reversed by arranging the gas and air flues in pairs one above the other, so that when a double sliding damper is in one position the gas and air flow through one regenerator, and when the damper is reversed they flow through a second regenerator.
—A. B. S.

Regenerator. W. Gast. U.S.P. 1,361,709, 7.12.20. Appl., 12.12.19.

The regenerator consists of a number of chambers in each of which a construction of chequer work is arranged, one of the chambers communicating with the inlet and another with the outlet of the apparatus. One of the chequer constructions is provided with gas-distributing channels situated close to the gas inlet and relatively larger in cross-sectional area than the respective chequer passages in the same chamber.—W. E. F. P.

Volatile solvents; Methods of recovering ——. H. Schmidt. E.P. 141,739, 15.4.20. Conv., 7.8.15.

Solvents evaporated during the drying of substances or articles are absorbed by an agent flowing through the drying chamber, and are subsequently recovered. The liquid absorbent may, for example, be allowed to flow along rods, threads, wires, textile fabrics, or the like arranged within the drying chamber.—W. E. F. P.

Volatile solvents; Removal of —— from materials treated therewith. H. Bollmann. E.P. 154,044, 21.10.19.

In a process of removing volatile solvents by conveying the material under treatment along a rising path against a counter current of steam, the material is subjected to alternate heating and cooling to enable the steam to penetrate better. Apparatus for this purpose may consist of an enclosed and inclined worm conveyor, the casing of which is formed of alternate hot and cold jackets.
—B. M. V.

Evaporators for liquids; Heat interchange devices such as ——. E. Wirth-Frey, Assee. of A.-G. Kummler und Matter. E.P. 142,077, 21.1.20. Conv., 23.4.19.

An evaporator has vertical heating channels formed by annular, hollow, heating bodies arranged concentrically one within the other; the channels are provided with scrapers which extend from above and operate in a resilient manner on the vertical walls. The scrapers are of clamp shape, removable, and mounted on a horizontal beam which is rotated about a vertical axis.—W. E. F. P.

Concentration, evaporation, and similar operations [e.g., for sulphite-cellulose waste lyes]. E. C. R. Marks. From Aktiebolaget Indunstare. E.P. 154,355, 3.9.19.

Concentration is effected in two or more stages by repeated circulation of the liquid as a thin film over a surface heated by the evolved vapour after compression of the latter to raise it to the necessary temperature, the solution being subjected to similar temperatures and pressures in the different stages, for the purpose of decreasing the total surface required for a given duty. The process is designed for use especially with liquids (such as sulphite-cellulose waste lye), the concentration of which increases the viscosity without affecting the boiling point appreciably.—W. E. F. P.

Evaporating process. J. C. Stead. E.P. 154,762, 14.10.19.

A pair of drying rolls, mounted to rotate side by side, has a trough-like duct arranged directly beneath the line of contact. Each roll has a casing on its under side, and the inside edges of the two casings are joined to the adjacent edges of the central trough. Between each roll and its casing

is an air space which gradually diminishes from the outside (or intake) edge towards the central duct; the latter is provided with a suction pipe for the purpose of drawing air from the atmosphere through these spaces, and with a drain pipe at its lowest part. The liquid to be evaporated is fed to the V-shaped space between the upper sides of the rolls.—W. E. F. P.

[Centrifugal] separators for granular and pulverulent materials, matter in suspension and the like. H. Hooke. E.P. 154,038, 9.10.19.

The basket of a centrifugal apparatus consists of two truncated cones with a common base and with sides forming acute angles with the base so that material shall not stick to the walls. Openings in the basket may be left at or just below the largest circumference for the discharge of concentrate, or the latter may be left in for removal later, the tailing in each case being discharged over the top edge of the basket. An annular feed member rotating in the same direction as the basket but at a different speed, delivers the material near the bottom of the basket and is continued upwards again as a flange parallel to the lower conical wall of the basket, and may be provided with stirring vanes. Alternatively, a diaphragm may be placed at the common base of the two cones, the feed being just above this, and holes left in the diaphragm near the circumference, so that only the concentrates will pass downwards.—B. M. V.

Centrifugal separator. C. P. Tolman, Assr. to National Lead Co. U.S.P. 1,358,897, 16.11.20. Appl., 2.4.17.

The separating chamber comprises two relatively separable sections between which the heavier material escapes through a peripheral annular outlet. Openings are provided in one of the sections for the escape of lighter material, and means are provided for rotating one of the sections relatively to the other.—J. H. L.

Separating liquids and solids; Method of and apparatus for ——. J. Avrutik. U.S.P. 1,360,708, 30.11.20. Appl., 2.7.19.

A continuous stream of the mixture is fed into and through a series of receptacles mounted in cascade fashion on the same vertical shaft, and is progressively subjected in successive compartments to a greater centrifugal liquid separating force, which is employed to feed the mixture from one receptacle to the next.—J. S. G. T.

Air saturating towers [for saturating air-blast with steam]. H. Nielsen and F. D. Marshall. E.P. 154,310, 21.8.19.

A closed, cylindrical tower provided with an inlet and an outlet for air at the lower and upper end, respectively, has an internal tube arranged concentrically, the annular space being packed with filling material. The inner tube is closed at the bottom, but has a lateral inlet pipe for water a short distance above, and is divided into sections by partitions. Each of the latter has an opening from which a tube depends into the next section below, and a valve discharge-pipe extends laterally from the top of each section through the annular space and the wall of the outer tower. The inner tube is open at the top, upon which a water-distributing device is disposed. The apparatus is designed to prevent clogging of the packing material by suspended matter in the water employed, part of the suspended matter being separated at the bottom of the inner tube and drawn off through a sludge cock, and the remainder trapped beneath the successive partitions and discharged through the lateral tubes.—W. E. F. P.

Cylinders for drying food; paper and such like. J. McIntyre, and J. Milne and Son, Ltd. E.P. 154,508, 12.4.20.

The ends (or plates covering the ends) of the cylinders are coated with glass or with vitreous or stove enamel, in order to facilitate cleaning. —W. E. F. P.

Drying apparatus. H. Wettig, Assr. to J. A. Topf und Soehne. U.S.P. 1,359,301, 16.11.20. Appl., 26.8.20.

Material is dried in a vertical shaft having reticulated walls for the passage of air. The shaft is divided into a number of sections, and the air is directed horizontally backwards and forwards through successive sections from the bottom to the top. Means are provided for passing either hot or cold air through the material.—W. F. F.

Drying machine. T. Allsop and W. W. Sibson, Assrs. to The Philadelphia Drying Machinery Co. U.S.P. 1,360,705, 30.11.20. Appl., 4.9.19.

A drying machine comprises a large chamber divided lengthwise into a series of zones through which the articles to be dried are successively passed. Means are provided for maintaining different temperatures and degrees of humidity in the various zones, and for circulating air within the chamber, the circulation in the first zone being more sluggish than in the others.—J. S. G. T.

Crystal production. R. W. Moore, Assr. to General Electric Co. U.S.P. 1,347,350, 20.7.20. Appl., 26.2.18.

To produce large and perfect crystals from solutions the saturated solution, at about 32°—35° C., is heated about 7°—8° C. above its saturation temperature, filtered, and placed in a vessel contained in a water bath surrounded by an electric heating coil. Small fragments of crystals are then suspended in the solution, which is maintained at about 0·5° C. above the saturation point. The setting of the thermostat by which the temperature is regulated is changed each day to produce a drop in temperature of about 0·1° C. per day, while evaporation is prevented. The decrease in temperature may be increased to a maximum of 0·6 C. per day after the crystals have grown to large size. —W. F. F.

Grinder and pulveriser; Compound ——. S. H. Herbst, jun. U.S.P. 1,358,739, 16.11.20. Appl., 9.3.20.

A grinding machine is provided with fixed inner and outer grinding rings, with a revolving series of grinding wheels between the rings. Alternate wheels are pressed by yielding means against the outer and inner rings, respectively, and each ring is provided with a sifting screen.—W. F. F.

Ball tube-mill; Combination ——. J. E. Kennedy. U.S.P. 1,360,648, 30.11.20. Appl., 12.10.17.

A combined ball and tube mill comprises a rotary tube with a sectional lining and a partition screen formed of a series of sectors, each sector having a relatively broad peripheral rim extending laterally on both sides of a perforated medial web. The lateral edges of the rims are in direct contact with the lining of the tube. The sectors of the partition are held rigidly at the centre and by the lining, and are thus prevented from moving longitudinally within the tube.—H. S. H.

Separator. J. T. Costello. U.S.P. 1,359,578, 23.11.20. Appl., 22.5.18.

A rotary drum having a porous periphery is partly immersed in a tank containing the mixture to be separated, and a vacuum is created within the drum whereby the liquid is drawn into it and the solid

deposited on its periphery. Means are provided for removing the solid deposit and for successively introducing compressed air into certain parts of the drum to clean the filtering medium.—W. F. F.

Slime-pulp thickener. C. Allen. U.S.P. 1,360,703, 30.11.20. Appl., 10.10.18.

A bag made of flexible material is contained within a settling tank provided with an orifice for the discharge of setled material, and communicates with a float chamber above. The float is actuated by the change in density of the medium surrounding the bag, and controls the size of the discharge orifice. Means are provided for registering the variation in the density of the pulp surrounding the bag. The buoyancy of the float may be adjusted, and the float may be connected with a discharge orifice so that liquid of a predetermined density may be discharged.—J. S. G. T.

Suspensions and colloids; Process for purifying —— by dialysis. W. Müller. G.P. 323,960, 21.3.19.

The liquid is evaporated considerably during dialysis by means of a vacuum or by heating it, *e.g.*, by blowing a current of hot air over the surface. Crystalloids are thus rapidly separated from the colloid.—A. R. P.

Alkali-resisting articles and apparatus. R. Rossberg. G.P. 326,032, 19.2.19.

Melting pots, tubes, evaporators, and the like to withstand the action of alkalis are made from practically chemically pure, carbon-free iron, *e.g.*, electrolytic iron, which has been melted in a vacuum or purified by any special process. Alloys of pure iron with nickel, tungsten, or the like are also suitable for making alkali-resisting apparatus. Sheets of pure nickel lost 0·5%, of electrolytic iron, 2·75%, and of Siemens-Martin iron, 26·5%, when fused with potassium hydroxide for 100 hrs.—A. R. P.

Roller-mill. F. E. Marcy. U.S.P. 1,361,601, 7.12.20. Appl., 25.1.19. Renewed 13.10.20.

See E.P. 136,950 of 1919; J., 1920, 391 a.

Gas and liquid contact device. C. J. Goodwin. U.S.P. 1,360,928, 30.11.20. Appl., 19.1.18.

See E.P. 110,260 of 1917; J., 1917, 1228.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Calculation of the efficiency of complete gasification from the analysis of ——. H. Strache and A. Gross. Mitt. Inst. Kohlenvergasung, 1920, **2**, 4—5, 45—46, 50—53, 59—61, 68—71. (*Cf.* J., 1920, 621 a.)

The efficiency of the various methods of gasification were calculated for different varieties of coal, taking as typical cases the production of semi-water gas, Mond gas, and compound gas ("double gas" or "tri-gas" processes). The efficiency calculated on tar-free coal varies (for the coals cited), for semi-water gas between 66·0 and 78·7%, for Mond gas between 47·2 and 52·1%, for compound gas ("double gas") without pre-drying and with excess steam between 74·0 and 83·7%, and for compound gas with pre-drying and without excess steam between 54·8 and 69·8%. In the semi-water gas process, by the use of warm water for moistening the air, an efficiency of 65—80% can be attained, according to the ash and water content of the coal; whilst in the Mond gas process the efficiency varies from 45 to 55%. The compound gas ("double gas") process, without pre-drying, is only practicable if the ratio of the water content of the coal to the ash-free coke is less than 2·60. If this ratio is smaller than 0·5, 10—20% excess steam can be used. The total efficiency lies between 80 and 85%. The compound gas process with pre-drying is only practicable if the ratio of water to ash-free coke is more than 2·60, or if the yield of ammonia makes it worth while. The efficiency of this process is 70—75%. The efficiency is not, however, the only criterion of the value of a process. Other factors may be of more importance, *e.g.*, the calorific value of the gas (especially where it is necessary to attain high temperatures), or the ammonia yield, which is high in the Mond process, although the efficiency is low. The quality of the tar again varies greatly according to the process adopted. The compound-gas process would be used where high-flame temperatures are necessary, where the gases are to be conducted to long distances, or where the yield and quality of the tar are of great economic importance.—A. G.

Cholesterol; Contact decomposition of ——. Theory of petroleum formation. W. Steinkopf, H. Winternitz, W. Roederer, and A. Wolynski. J. prakt. Chem., 1919, **100**, 65—85.

The view that the optical activity of petroleum originates from cholesterol and its derivatives accounts for most of the facts, with the exception that whilst the decomposition products hitherto prepared from cholesterol are all dextro-rotatory, certain fractions of petroleum exhibit lævo-rotation. It is now found, however, that if cholesterol be heated alone at 150°—200° C., or in presence of kieselguhr at 150° C., the lævo-rotation gradually diminishes to a minimum and then increases; in presence of quartz at 200° C. the diminution is continuous, and eventually dextro-rotatory products are formed. It is suggested that under the conditions prevalent in nature cholesterol furnishes first a lævo- and ultimately a dextro-rotatory cholesterylene, which subsequently give products, some richer, some poorer in hydrogen.—J. K.

Petroleum; Specific heat of —— at different temperatures. F. W. Bushong and L. L. Knight. J. Ind. Eng. Chem., 1920, **12**, 1197—1200.

The specific heats of petroleum products at different temperatures are recorded graphically and also in tabular form. For solid paraffin the value varies from 0·12 at −210° C. to 0·47 at 0° C.; for liquid paraffin the value increases from 0·5700 at 52° C. to 0·6307 at 100° C. For petroleum distillates the values 0·4703 at 21·1°C. and 0·5420 at 68° C. are given.—W. P. S.

Petroleum, tar, etc.; New method of fractional distillation of ——. H. Offermann. Chem.-Zeit., 1920, **44**, 773—774.

The author modifies the usual method of obtaining the heavy fractions of petroleum and similar materials, namely, distillation with superheated steam, by using wet steam at 100° C., and claims to achieve higher yields of more viscous oils and smaller amounts of pitch. The explanations he suggests are that cool steam (plus entrained water) represents a greater quantity of water than superheated steam per unit volume; and that the evaporation of entrained water droplets within the oil increases the efficiency of contact of steam with oil.—A. E. D.

Gasoline left in residual gas from compression plants; Absorption as applied to the recovery of ——. W. P. Dykema and R. O. Neal. U.S. Bureau of Mines, Tech. Paper 232, 1920. 40 pp.

The absorption method of recovering gasoline is more efficient than compression, and is applicable either to rich gas (3 to 6 galls. of gasoline for 1000 cb. ft.) or to the residual lean gases from compression plants. Using naphtha as absorbent a plant to handle 500,000 cb. ft. per day can be in-

stalled for less than $1000. Details are given of satisfactory units, baffling devices, packing, rates of flow, and the recovery of gasoline from the absorbent by distillation. Portable testing apparatus for determining the gasoline content of natural gas is also described.—A. E. D.

Paraffin wax; Analysis of ——. K. Bube. Petroleum, 1920, **16**, 5—8. Chem.-Zentr., 1920, **91**, IV., 350.

The specific gravity at 50° C. of lignite paraffin wax increases nearly linearly with the addition of dark paraffin oil, and it has been found that the difference between the sp. gr. at 50° C. and 0·784 in units of the third decimal place gives the percentage content of dark paraffin oil if hard paraffin wax (m.p. about 50°) is used. With soft paraffin wax and intermediate qualities the figures 0·781 and 0·782, respectively, should be substituted. The results are accurate to 1—2% provided that the content of oil is under 44%. The method is useful for controlling the sweating process.—A. E. D.

Viscosities of liquids at high pressures; Apparatus for determination of absolute —— and results obtained with it for certain lubricating oils. J. H. Hyde. Report of Lubricants and Lubrication Inquiry Committee. (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 80—84.

In the method described a closed system of two horizontal tubes (the upper one capillary in dimensions) and two vertical tubes is used. The lower half of the system contains mercury and the upper half the liquid under investigation. Any desired pressure and temperature may be maintained in the apparatus. One end of the system rests on a horizontal knife edge and the other is carried by a spiral spring. On the mercury being displaced by a given amount, flow will take place round the circuit owing to difference of head, and if the spring be so designed that its rate of extension is equal to the change of head of the mercury, flow of the liquid under test will take place through the capillary under constant pressure difference and at a velocity calculable from the rate of extension of the spring. All the data needed for the determination of absolute viscosity are thereby obtained. Illustrations are given showing the construction of the viscosimeter, the general arrangement of the viscosimeter and heating bath, and a pressure intensifier for use with the apparatus. All the oils tested showed rapid rise of viscosity with pressure (see following table in which η=viscosity and ρ= density):—

	Pressure, tons per sq. in.	Value of η/ρ C.G.S. units.	Temp., ° C.
Castor oil	1·44	227·5	40·2
"	5·49	864·5	40·0
"	7·39	1164·0	40·5
"	(atmospheric)	1·94	—
Mobiloil B.B. (mineral)	1·44	227·5	40·0
"	4·51	710·0	39·8
"	6·47	1019·0	40·0
"	(atmospheric)	1·58	40·0
Bayonne (mineral)	1	157·5	39·9
"	4	630·0	40·0
"	8	1260·0	40·0
"	(atmospheric)	0·49	40·0

—A. E. D.

Lubricating oils; Compressibility of —— under high pressures, and the application of the results to the tests in the high-pressure viscosimeter to obtain the values of the viscosities of the oil. J. H. Hyde. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 86—90.

The expression η/ρ in the previous report (*cf. supra*) was used in the absence of data relative to the densities of the material under high pressures. To obtain such data a steel cylinder filled with the liquid under test and fitted with a sleeved plunger was used, this being immersed in the liquid contained in a strong tube and the pressure in the tube raised to the desired amount. When the pressure was released the motion of the plunger was determined by its position relative to the sleeve, which was held by springs in the new position created by the applied pressure. The compressibilities of the oils and of water were determined and were found not to differ materially from one another:—

Pressure, tons per sq. in.	Densities at 40° C. Castor oil.	Sperm oil.	F.F.F. cylinder.	Mobiloil B.B.
0	0·9415	0·866	0·877	0·899
4	0·9685	0·896	0·904	0·920
8	0·9905	0·9195	0·926	0·949
10	1·001	—	—	—

—A. E. D.

Viscosity of liquids at high pressure; Absolute ——. Results of tests on rape, sperm and FFF cylinder oils. J. H. Hyde. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 85.

Rape and sperm oil do not materially differ from castor oil in their behaviour; similarly the mineral oil resembled the mobiloil and Bayonne lubricating oil previously tested (*cf. supra*).—A. E. D.

Viscosity of oil at high pressure; Testing the ——. C. A. Parsons. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 98—99.

The shape and position of oil grooves in the bush seem to have a great effect on the friction. In turbine bearings large oil grooves are provided, and the heat is carried away by pumping a large volume of oil through the bearings, the oil being cooled and then returned to the bearings.—A. E. D.

Viscosity of oils under any pressure; Apparatus for examination of ——. C. V. Boys. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 100—101.

A driven tubular shaft carries at its end within a chamber in a strong steel block a cylindrical shell, the exterior surface of which is the inner surface of the oil film. The outer oil film surface is formed by the inner surface of a sleeve surrounding the shell. The sleeve is carried by a gimbal ring held by a slender tubular shaft in line with the driven shaft and free to turn in the cover of the steel block, and a tubular extension of the same. The tubular extension is partly cut away to carry a block, which is provided with a pointer and counterweight.

—A. E. D.

Viscosimeter; Cup and ball ——. T. C. Thomsen. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 104—110.

The most accurate results are obtained when the ball and cup are both immersed in oil heated to a desired temperature. The cup is pressed on the ball, the instrument suspended in the oil, and the time taken for the ball to drop is ascertained. The rougher method, in which a few drops of oil are inserted between the cup and ball, the two parts pressed together and then suspended and the time interval of contact noted, is less accurate. Particular care must be taken with regard to temperature regulation, and if proper care is taken results comparable with those given by Redwood's viscosimeter are obtainable.—A. E. D.

Oil emulsions; Memorandum on Patterson's suggested method of preventing the separation of —— when mixed with salt water. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 115.

"Acme" cutting compound (emulsion of mineral

oil, soap, and water) was diluted with water and with salt solution of various concentrations. Salt up to 0·2% did not cause appreciable separation of the emulsion. When salt was present in amounts sufficient to cause separation, the addition of gelatin, as suggested by Patterson, did not prevent the separation.—A. E. D.

Graphite; Effect of —— on lubricants. Tests on the Lanchester worm gear testing machine. J. H. Hyde. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 75—79.

FLAKE graphite gave marked improvement in efficiency when added to some oils and little change with others. Where improvement was shown it was in excess of that obtained with "oildag." Broadly speaking, "oildag" and flake graphite had a beneficial effect under the conditions of the tests. Even when they did not materially raise the efficiency, however, they appeared to have the effect of raising the temperature at which a serious fall in efficiency occurred.—A. E. D.

"Oildag" in aero-engines; Trials of —— by the Air Ministry. Report of Lubricants and Lubrication Inquiry Committee (Dept. of Sci. and Ind. Res. Advisory Council), 1920, 117—124.

THE results of the tests indicate that "oildag" helps towards maintaining good running conditions, full power output over an extended run, and reduction in mechanical losses, but the saving is only a small fraction of the total power output, and is probably more than counterbalanced by the accompanying disadvantages.

PATENTS.

Coal and the like; Apparatus for washing ——. R. A. Henry. E.P. 153,790, 4.12.19.

WATER charged with coal or ore is supplied by a centrifugal pump to one end of a trough having an aperture in its bottom through which another stream of water flows upwards. The heavier particles fall through this opening into a receptacle from which they are removed by a bucket conveyor. The lighter particles pass onward through the trough to an outlet at the other end, while the unclassified material passes through other apertures in the bottom, and thence back to the pump in a closed circuit for further classification.—W. F. F.

Coal or other mineral washing apparatus. A. France. E.P. 153,983, 27.8.19.

COAL is washed in a number of superposed troughs, each provided with separators, and the schist etc. is discharged from the lowest trough to a reservoir. The solid material in the reservoir, consisting of heavy material from the upper troughs and light material from the separators of the lowest trough, is lifted by an elevator to the uppermost trough for further washing.—W. F. F.

Coal and like material; Jig for separating —— from foreign matter. C. V. King. U.S.P. 1,360,116, 23.11.20. Appl., 17.4.19.

A SEPARATING chamber with an inclined perforated floor is formed as a compartment in a tank, and water is forced upwards through the floor by a piston reciprocating in another compartment in the tank. A settling chamber is provided at the forward end of the inclined floor, and has two inclined faces, which direct the material to an outlet between them. The settling and separating chambers are separated by a vertical partition, the lower end of which is spaced from the floor so as to leave a passage between the two chambers. Water and lighter materials overflow above the settling chamber, and another portion of the separated material collects behind a vertically adjustable plate at the rear of the separating chamber. —W. F. F.

Fuel; Composition ——. D. B. Macdonald, and The Densified Peat Fuel and Products, Ltd. E.P. 154,289, 18.8.19.

A MIXTURE of moist peat (1 pt.), reduced to a pulp with or without the addition of hot or cold water, and coal dust (1 pt.) is worked in a pug-mill, formed into blocks, and dried. (Reference is directed in pursuance of Sect. 7, Sub.-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2237 of 1873, 654 of 1875, 1806 of 1889, 17,154 of 1890, 16,027 of 1902, and 122,214.)—L. A. C.

Artificial fuel; Manufacture of ——. J. W. Leadbeater. E.P. 154,319, 23.8.19.

PEAT (168 lb.) containing 50—60% of moisture, from the black, lower peat strata, is disintegrated and mixed with about 8 lb. of pitch, 4lb. of ground slaked or unslaked lime, and 270 lb. of fine coal. The product is ready for use without compression into briquettes.—L. A. C.

Coke-oven heating wall and the like. A. Roberts, Assr. to American Coke and Chemical Co. U.S.P. 1,358,787, 16.11.20. Appl., 27.1.19.

A COKE-OVEN heating wall is built up of courses of blocks, each having a recess extending over two of its adjoining faces, the recesses in adjacent blocks being contiguous. Each block is provided in the corner opposite to the recess with a flat portion for jointing to a corresponding flat portion of a brick in the next course. The jointing portions have their edges bevelled, and their jointing faces are alternately at the top and bottom of the course, while all face in the same direction along the length of the wall.—W. F. F.

Coke and the like; Method relating to the quenching of hot ——. R. and J. Dempster, Ltd., and G. F. H. Beard. E.P. 153,838, 31.3.20.

HOT coke is carried by a conveyor which moves just below the surface of the water in a tank, so that the coke is quenched by a comparatively small amount of water or by the steam generated from it. The forward edges of the conveyor plates may be bent downwards to disturb the surface of the water and wash it against the coke. Means may be provided for varying the level of the quenching liquid or the height of parts of the conveyor.—W. F. F.

Carbonisation or destructive distillation [of finely subdivided fuel]; Method of and apparatus for ——. Underfeed Stoker Co., Ltd., and S. McEwen. E.P. 154,253, 18.6.19.

POWDERED coal is carbonised to a finely subdivided coke as follows. The powdered fuel is conveyed into the bottom of an upwardly expanding chamber by a current of the gas produced in carbonisation mixed with the hot products of the combustion of part of this gas in a separate furnace with a minimum excess of oxygen. The upward blast produces a relative movement between the gas and the particles and allows the larger particles the longest time for carbonisation. The carbonised dust is separated in a "cyclone" and the gases scrubbed for oil.—C. I.

Carbonisation of finely subdivided fuel. Underfeed Stoker Co., Ltd., and S. McEwen. E.P. 154,458, 18.6.19.

POWDERED coal is carbonised in such a manner that it retains its powdered form, *e.g.*, by allowing it to fall freely in a vertical retort, and is then showered into a current of the gas produced in the carbonising retort and conveyed by it into a combustion chamber.—C. I.

Suction gas producer. H. Bloomfield and F. J. Morgan. E.P. 154,436, 14.11.19.

A GAS producer is surrounded by a double jacket. The exhaust gases from the gas engine circulate through the outer jacket and serve along with the heat of the producer to raise steam in the inner jacket. A supplementary gas-fired boiler may be provided in the form of an annular chamber around the lower part of the producer.—C. I.

Gas; Apparatus for the manufacture of ——. M. C. Whitaker and W. F. Rittman, Assrs. to Synthetic Hydro-Carbon Co. U.S.P. 1,348,766, 3.8.20. Appl., 28.2.16.

LIQUID substances which are to be brought into reaction, *e.g.*, mineral oils, are admitted to the upper end of a vertical cylinder containing a quantity of small pieces of refractory material supported on a perforated plate. The main part of the cylinder is unobstructed and is surrounded by an electric heating coil, the whole cylinder being heat-insulated. The upper part of the cylinder is heated sufficiently to gasify the liquid instantaneously, and the products pass out at the bottom to a condenser and thence to a collecting vessel. Means are provided for controlling the pressure and temperature within the reaction chamber.—W. F. F.

Producer gas; Process for making or treating ——. W. B. Chapman and D. Mason, Assrs. to Chapman Engineering Co. U.S.P. 1,361,137, 7.12.20. Appl., 16.3.15.

THE fuel from which the gas is produced is led into a heated gasifying chamber, and the resulting gases, while hot, are subjected to the action of an ionising medium in a separate chamber.—A. J. H.

Gas-washing apparatus. H. Neilsen and F. D. Marshall. E.P. 154,309, 21.8.19.

A SCRUBBING tower is provided on both sides with shelves inclined inwards and extending nearly to the opposite side of the tower. There are two vertical revolving shafts each carrying a spraying basket for every compartment in the tower. Curtains of perforated plate, metal strips, chains, or strings of beads are hung between the spraying baskets. The shelves are provided with ridges to guide the liquid collecting on them through the openings in the shelves for the shafts and into the baskets underneath.—C. I.

Gas; Purification of —— *[from naphthalene].* C. E. Holt and J. S. Burgoyne. E.P. 154,742, 20.9.19.

GAS is passed through a helical screen of wire gauze of gradually increasing fineness. The meshes are sufficiently coarse not to become clogged with tar, and films of oil form in them and absorb naphthalene. The deposited matter drops off and is removed, and the degree of purification is regulated by the temperature.—C. I.

Gas; Purification of —— *[from sulphur compounds].* H. L. Doherty. U.S.P. 1,360,734, 30.11.20. Appl., 22.5.17.

NATURAL or other gas is purified from acid gases without loss of pressure as follows. It is scrubbed under pressure with a stream of ammonia solution, the resulting liquor heated, the ammonia removed from the gas given off, and the ammonia and water returned to the scrubber.—C. I.

Mineral oil; Process of purifying used ——. The De Laval Separator Co., Assees. of C. H. Hapgood. E.P. 142,089, 6.4.20. Conv., 23.4.19.

OLEIC acid (3 lb.) is added to dirty lubricating oil (100 gals.), from which gasoline, if present, has been previously removed by treatment with steam or hot air, and the mixture is agitated at 180° F. (about 80° C.). A solution of 1½ lb. of soda ash and 1¼ lb. of sodium chloride or sulphate in 9 galls. of water is added, and the oil is separated from the aqueous solution, which contains the suspended carbon and dirt from the oil, by centrifugal means. —L. A. C.

[Motor] fuel; Non-freezing ——. E. C. R. Marks. From U.S. Industrial Alcohol Co. E.P. 153,925, 7.5.19.

A FUEL for internal combustion engines, which is non-freezing at −60° F. (−51° C.), consists, according to one example, of ethyl alcohol 40 pts., gasoline 28 pts., benzol 17 pts., ether 7·5—10 pts., and toluol 8 pts. In other examples kerosene and methylethyl ketone are used as ingredients.—W. F. F.

Fuel; Non-freezing ——. E. C. R. Marks. From U.S. Industrial Alcohol Co. E.P. 154,867, 7.5.19. (*Cf.* 153,925, *supra.*)

AN internal combustion engine fuel which does not freeze above about −60° F. (−51° C.) consists of 12 pts. by vol. of benzene, 30 pts. of gasoline, and 40 pts. of absolute alcohol.—L. A. C.

Hydrocarbon oil; Treatment of ——. N. V. S. Knibbs. E.P. 154,464, 20.12.19.

HYDROCARBON oil is decomposed, with formation of products of lower boiling point, by heating with an alkali metal, *e.g.*, sodium, or an alloy of the same, *e.g.*, sodium-lead alloy, either in a still fitted with a fractionating column, or in an autoclave, or by passing the oil vapour through the molten metal. —L. A. C.

Hydrocarbon oils; Apparatus for treating ——. M. J. Trumble, Assr. to Shell Co., of California. U.S.P. 1,349,794, 17.8.20. Appl., 19.7.16.

OIL is sprayed into a separator through an opening through which hot furnace gases are also introduced in the same direction.—A. E. D.

(A, C) *Hydrocarbons; Apparatus for cracking* ——. (B) *Cracking hydrocarbons.* J. W. Coast, jun., Assr. to Process Co. U.S.P. (A) 1,349,815, (B) 1,349,816 and (C) 1,349,817, 17.8.20. Appl., 27.9.17.

(A) A FIRE-HEATED cracking still is provided with a circulating pump and filter both inside the still. The pump is operated by means outside the still and withdraws oil from the bottom of the still, forces it through the filter to remove coke-forming matter, and returns the filtered oil to the main body of oil. (B) A pressure still operating at more than 3 atm. pressure has an arcuate bottom provided with scrapers whereby the coke is continuously moved from the middle to opposite sides of the still and accumulated at high levels away from the hottest portion of the bottom of the still. (C) A scraping device for a still of the type described in (B), consists of a series of chains, the links of which are in scraping contact with the arcuate bottom. The chains are suspended from arms attached to a horizontal oscillatory shaft.—A. E. D.

Petroleum oils; Process of desulphurising ——. E. B. Cobb, Assr. to Standard Oil Co. U.S.P. (A) 1,357,224 and (B) 1,357,225, 2.11.20. Appl., 13.3.19.

THE oil is freed from elementary sulphur by treatment with (A) an alkaline hydroxide and hydrogen sulphide or (B) an alkaline-earth sulphide. —A. E. D.

(A, C) *Hydrocarbon oils; Apparatus for treatment of* ——. (B) *Process for treatment of hydrocarbon oils.* R. B. Day, Assr. to A. B. Adams. U.S.P. (A) 1,357,276, (B) 1,357,277, and (C) 1,357,278, 2.11.20. Appl., (A, B) 27.7.18, (C) 30.7.18.

(A) OIL is heated in a coil situated in a distilling chamber which is a continuation of a cracking

chamber heated by gaseous products of combustion. The vapour distilled from the oil passes into the cracking chamber. (B) Oil is fractionated, and the several fractions are cracked by contact with hot inert combustion gases. The heat of the cracked products is utilised to fractionate further quantities of oil. (C) Shale is treated with hot combustion gases whereby oil is first distilled and secondly cracked.—A. E. D.

Hydrocarbons; Method of and apparatus for cracking ——. F. Puening. U.S.P. 1,358,174, 9.11.20. Appl., 21.12.16.

A BODY of oil is maintained in a chamber immediately above a cracking chamber in which there is a number of vertical tubular stills. The oil passes into the stills through pipes extending to the lower end of the latter, and a gas or vapour may be introduced at the lower ends of the pipes to promote circulation or decomposition.

Hydrocarbons; Furnace for treating ——. C. C. Stutz, Assr. to Synthetic Hydrocarbon Co. U.S.P. 1,359,931, 23.11.20. Appl., 30.10.15. Renewed 15.3.19.

A NUMBER of vertical tubes are arranged with their upper ends enclosed within chambers. The chambers are connected at their upper ends with a combustion chamber and at their lower ends with flues leading to a stack. The lower ends of the tubes are similarly enclosed within independent chambers which are connected with an independent combustion chamber and the stack.—J. S. G. T.

Fuel; Liquid ——. J. Black. U.S.P. 1,360,872, 30.11.20. Appl., 18.8.19.

THE fuel consists of 5 galls. of gasoline, 16 oz. of ether, 100 oz. of acetone, 14 oz. of alcohol, and 100 galls. of the distillate obtained by distilling a mixture of an aliphatic hydrocarbon of less than 50° B. (sp. gr. 0·778) with 10% of benzene, the distillate having a higher sp. gr. than the aliphatic hydrocarbon.—L. A. C.

Coal, tar, heavy oils resulting from the distillation of bituminous coal, etc.; Process of treating ——. C. S. Palmer, Assr. to Standard Oil Co. U.S.P. 1,360,973, 30.11.20. Appl., 29.8.17.

THE material is digested, without addition of steam, using a pressure above 4 atm., and a temperature above 200° C., but below that at which sufficient carbonisation occurs to interfere with the process, until the greater portion is transformed into readily volatile products.—L. A. C.

Coal; Concentration of bituminous —— by flotation. W. J. Mellersh-Jackson. From Metals Recovery Co. E.P. 154,702, 2.9.19.

SEE U.S.P. 1,329,493 of 1920; J., 1920, 220 A.

Gas from coal and analogous substances; Means to generate ——. J. H. Corthesy, Assr. to S. T. S. Castelli. U.S.P. 1,360,503, 30.11.20. Appl., 10.5.19.

SEE E.P. 127,933 of 1918; J., 1919, 565 A.

Shale and the like; Process of and apparatus for recovering bitumens from ——. H. D. Ryan. E.P. 129,992, 16.7.19. Conv., 28.3.18.

SEE U.S.P. 1,327,572 of 1920; J., 1920, 182 A.

Fuels; Liquid ——. U.S. Industrial Alcohol Co., Assees. of A. A. Backhaus. E.P. 140,796, 25.3.20. Conv., 12.10.17.

SEE U.S.P. 1,271,114 of 1918; J., 1918, 539 A.

Motor-fuel. A. Hayes, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,361,153, 7.12.20. Appl., 27.8.19.

SEE E.P. 153,925 of 1919; preceding.

Coke-chamber and discharging-guide therefor. L. Wilputte, Assr. to A. A. Wilputte. U.S.P. 1,360,608, 30.11.20. Appl., 4.5.18.

Gas retorts and the like; Mouthpieces for vertical ——. Goodall, Clayton, and Co., Ltd., C. R. Payne, and J. A. Archdale. E.P. 154,758, 6.10.19.

Gas producers; Fuel feeding and distributing devices for ——. H. Nielsen and F. D. Marshall. E.P. 154,307, 21.8.19.

Regenerative ovens. U.S.P. 1,361,595. *See* I.

Asphalts. G.P. 325,780. *See* V.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Acetic acid in pyroligneous acid; Determination of ——. V. E. Grotlisch. J. Ind. Eng. Chem., 1920, 12, 1183–1186.

TEN c.c. of the crude acid is distilled with 120 c.c. of xylene and the distillate, after dilution with water, is titrated with $N/2$ sodium hydroxide solution using phenolphthalein as indicator. The aqueous portion is then separated from the xylene and evaporated to a volume of about 70 c.c., 100 c.c. of water is added, the mixture again evaporated and these operations repeated several times to expel esters, acetone, etc. Other volatile matters are then oxidised by treating the hot solution with permanganate (this does not act on the acetate), the mixture filtered, diluted to 300 c.c., and 200 c.c. of the filtrate is evaporated to 70 c.c., treated with a few drops of concentrated sulphuric acid and hydrogen peroxide to destroy excess of permanganate, a slight excess of barium hydroxide solution is added, the mixture evaporated to a small volume, filtered out of contact with air, and the filtrate containing the acetate then distilled with phosphoric acid in the usual way.—W. P. S.

PATENTS.

Coal, shale, or other bituminous substances; Apparatus for the low-temperature distillation of ——. K. Prinz zu Löwenstein, A. Irinyi, and T. Kayser. E.P. 144,712, 10.6.20. Conv., 28.10.18.

COAL, shale, or the like is distilled in a double-walled retort heated by steam or hot air passed through the jacket. The retort contains a hollow screw-conveyor through which steam or hot air is also passed from end to end through the blades. The conveyor is automatically scraped by means of an endless band moving over shafts and carrying ribs which project downward between the blades of the conveyor and are moved forward by the rotation of the screw.—W. F. F.

Volatile hydrocarbons; Apparatus for treating carbonaceous material for the recovery of ——. C. C. Bussey. E.P. 154,658, 29.7.19.

IN a continuously acting retort for the low-temperature distillation of coal, lignite, or shale, the heat is supplied entirely by the partial combustion of the material at the bottom of the retort. Clogging of the retort is avoided by the use of a water-cooled ejector bar at the bottom, which removes the coked residue alternately in opposite directions. The temperature is kept low enough to avoid cracking of the distillation products with formation of tar, and the weight of the fuel bed causes the formation of a hard coke even from cannel coal.—C. I.

Distillation ovens. G. B. Ellis. From Foundation Oven Corp. E.P. 154,819, 29.1.20.

In a retort for the low-temperature distillation of coal, lignite, or peat, with continuous top feed, the walls of the annular heating flues are made of fireclay brick in the upper part of the retort and of silica brick in the lower part. Separate exits are provided from appropriate parts of the retort for ammonia-, tar-, and moisture-containing gases, and the temperatures of the different zones are regulated by introducing additional gas or cooling air through a number of holes in the annular heating flues.—C. I.

Decolorising carbons; Process of making ——. R. W. Mumford, Assr. to Refining Products Corp. U.S.P. 1,359,094, 16.11.20. Appl., 23.3.18.

A stiff pasty mixture containing powdered coal-like matter, tarry matter, and ammoniacal liquor, is charred in a vented retort through which steam is passed to facilitate the removal of vapours, and the temperature is slowly raised to above 600° C. —J. H. L.

Mantles for gas lighting by incandescence. R. H. Stevens. E.P. 154,138, 2.6.20.

To increase the mechanical strength of incandescence mantles they are treated with a thin paste formed of kaolin or like clay mixed with phosphoric acid or with phosphoric acid and aluminium silicate. In the case of inverted mantles, the supporting ring is preferably roughened or provided with holes to facilitate adhesion of the paste, and the paste is applied to the regions around and adjacent to the ring. In the case of upright mantles, the loop and shoulder are coated, preferably on the inner and outer sides. The paste may be applied to mantles in course of manufacture or subsequently.—J. S. G. T.

Metal filament; Process for heating a —— to any desired temperature. Siemens und Halske A.-G. G.P. 325,644, 18.9.18.

A positively charged electrode is arranged in proximity to the filament so that a current passes between it and the filament, and the heating current of the latter is so regulated that a definite relation between the saturation current and the heat energy is obtained. For example, for the production of a standard lamp which will always give approximately the same amount of light, a metal electrode is arranged near to the filament so that a stream of electrons passes between them.—A. R. P.

Arc lamp carbons; Metal-coated ——. Siemens-Schuckertwerke G.m.b.H. G.P. 325,803, 29.6.19. Conv., 2.10.17.

Cathode carbons for arc-lamps taking heavy currents are provided with a number of channels or depressions which are completely filled by the metal coating. The latter consists of first, a thin coating of a noble metal, *e.g.*, silver, then a thicker coating of a base metal, *e.g.*, copper.—A. R. P.

III.—TAR AND TAR PRODUCTS.

Lignite tar oils; Composition of ——. A. Grün and E. Ulbrich. Z. angew. Chem., 1920, 33, 295—296.

A lignite tar oil (b.p. 180°—260° C.), obtained from a Mond gas producer, after removal of phenols and amines, was distilled with superheated steam; it had b.p. 240°—260° C., sp. gr. at 17·5° C. 0·940, and iodine value (Wijs) 54·84. The bromine addition value was 11·06 and the bromine substitution value 48·78. The oil was then freed from olefines and "naphthylenes" in the usual way, *i.e.*, with a mixture of concentrated and fuming sulphuric acid and then by means of the formolite reaction; the bromine addition value was thereby reduced to 0, whilst the bromine substitution value was still about 29, showing that saturated hydrocarbons were present which combined with bromine. The iodine value of the oil does not, therefore, represent the amount of unsaturated substances in the oil. —W. P. S.

Benzene; Freezing point of wet —— and the influence of drying agents. N. V. Sidgwick. Chem. Soc. Trans., 1920, 117, 1340—1343.

The freezing point of repeatedly purified, dry benzene is lowered 0·100° C. by saturation with water. On the addition of various dehydrating agents water is withdrawn from the benzene to varying extents depending on the efficiency of the drying agent employed, and the freezing point is correspondingly raised, and a convenient method is thereby afforded for determining the relative efficiency of the drying agents. This efficiency will be the same (at temperatures near 5° C.) for a solution in any solvent in which the drying agent is insoluble. The freezing point of the wet benzene was raised by various drying agents as follows:—sodium sulphate, 0·024° C.; potassium carbonate, 0·061°; copper sulphate, 0·089°; calcium chloride, 0·091°; sodium hydroxide, 0·098°; phosphoric oxide, 0·100° C. The removal of water by phosphoric oxide is therefor apparently complete.—G. F. M.

Sulphonation; Catalytic action of iodine in ——. I. J. N. Rây and M. L. Dey. Chem. Soc. Trans., 1920, 117, 1405—1407.

Iodine acts as a positive catalyst in sulphonation. Ordinary concentrated sulphuric acid (sp. gr. 1·84) with a trace of iodine can advantageously be used in place of fuming sulphuric acid. The nature of the product is sometimes changed, thus rendering easy the preparation of acids otherwise difficult to obtain. The catalytic sulphonation is facilitated by the presence of an amino-, hydroxy-, or halogen-group, proceeds with less ease with carboxylic acids, and is inhibited by the nitro-group, and probably also by the sulphonic-group, since disulphonic acids are never obtained. There is an optimum temperature for each reaction at which maximum transformation takes place. Among the more noteworthy results toluene gives a 90—95% yield of the *p*-sulphonic acid, benzoic acid a 95% yield of the *ortho*-acid, and chlorobenzene an 85% yield of the *para*-acid.—G. F. M.

Naphthalene-2.7- and 1.6-disulphonic acids; Method for the detection of ——. J. A. Ambler. J. Ind. Chem., 1920, 12, 1194—1195. (*Cf.* J., 1920, 815 A.)

The dry acetone-insoluble β-naphthylamine salts of the acids are boiled with a small quantity of a mixture of 95% alcohol, 4, and water, 1 vol., the mixture filtered, and the filtrate cooled; the β-naphthylamine salt of the 2.7-disulphonic acid crystallises out. Another portion of the dry salts is boiled with water and titrated with $N/1$ sodium hydroxide solution, using phenolphthalein as indicator; the precipitated amine is filtered off, and the filtrate evaporated to dryness. The dry residue is dissolved in twice as much water as the volume of sodium hydroxide solution used, and the solution is treated with its own volume of concentrated sulphuric acid; on cooling, the sodium salt of the 1.6-disulphonic acid crystallises out gradually (after some hrs.) whilst the 2.7-acid remains in solution. —W. P. S.

Methyl derivatives of the xylidines and naphthylamines; Preparation of —— by catalysis. A. Mailhe and F. de Godon. Comptes rend., 1920, 171, 1154—1155.

When a xylidine or naphthylamine is mixed with

methyl alcohol and passed in the form of vapour over alumina at 360°—380° C., in all cases a mixture of methyl and dimethyl derivatives is obtained, the whole of the primary base being methylated.—W. G.

Distillation of tar. Offermann. *See* IIA.

Toluene from turpentine. Mahood. *See* XX.

Phenols. Fuchs and Elsner. *See* XXI.

PATENTS.

Hydrogenation apparatus. The Dayton Metal Products Co., Assees. of T. Midgley, jun. E.P. 150,991, 7.5.19. Conv., 5.10.18.

CLAIM is made to apparatus suitable for hydrogenating benzene as described in E.P. 133,666 (J., 1920, 717 A).—L. A. C.

Treating tar oils. U.S.P. 1,360,973. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

ar-Dihydro-α-naphthylamines and their derivatives. Studies in the dihydronaphthalene series. I. F. M. Rowe and E. Levin. Chem. Soc. Trans., 1920, **117**, 1574—1579.

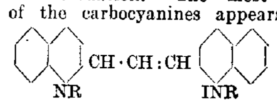
THE most suitable compounds to prepare for the purification and characterisation of α-naphthylamine, its two dihydro-derivatives, and its tetrahydro-derivative are the benzylidene derivatives, which are readily obtained in a pure condition from each of the crude bases, and which, on hydrolysis, yield the pure bases. The dihydro-α-naphthylamines condense with diazonium salts, with the direct formation of aminoazo-compounds, and they may also be diazotised and combined with amines or phenols, forming azo-dyes, which differ in shade from similar azo-dyes derived from α-naphthylamine or *ar*-tetrahydro-α-naphthylamine. The shade produced by an azo-derivative of 5.8-dihydro-α-naphthylamine is more nearly related to that produced by a similar azo-derivative of α-naphthylamine, whilst the shade produced by a 7.8-dihydro-α-naphthylamine derivative is more nearly related to that produced by a similar tetrahydro-α-naphthylamine derivative.—F. M. R.

Carbazole Blue and Carbazole Violet. M. Copisarow. Chem. Soc. Trans., 1920, **117**, 1542—1550.

CARBAZOLE Blue, obtained by fusing carbazole with oxalic acid, is a tricarbazylmethane colouring matter of formula, $(C_{12}H_7NH)_2C:C_{12}H_7NH.CO_2H$, and it may reasonably be assumed that the methane carbon atom is linked to each carbazole nucleus at the *p*-position with respect to the nitrogen atom. Carbazole Blue, like the triphenylmethane dyes, furnishes a carbinol which gives with acids variously coloured salts, of which the formate is identical with the colouring matter. The corresponding tricarbazylmethane, prepared by reducing Carbazole Blue, forms white, rhombic needles, m.p. 217°—218° C. When 9-ethylcarbazole is fused with oxalic acid, a violet colouring matter (Carbazole Violet) is obtained, and the carbinol and parent hydrocarbon of this compound have also been prepared. Both Carbazole Blue and Carbazole Violet are readily sulphonated, and consequently the presence of a phenylene group, like that of the benzyl and phenyl groups, makes possible the production of soluble dyes of the triphenylmethane series.—F. M. R.

Cyanine dyes. III. Constitution of Pinacyanol. W. H. Mills and F. M. Hamer. Chem. Soc. Trans., 1920, **117**, 1550—1562.

PINACYANOL (E.P. 16,227 of 1905; J., 1906, 368) is an example of the class of blue sensitising dyes for which the name carbocyanines has been proposed. The structural formula advanced by O. Fischer (J., 1919, 199A) does not appear to represent the composition of these dyes correctly, as it contains one atom of carbon less than is indicated by the analytical results, whilst the representation of the carbocyanines by Wise, Adam, Stewart, and Lund (J., 1919, 456A) as dimethyl derivatives of the true cyanines is not in accord with their photosensitising action, nor does it agree with their behaviour on oxidation. The most probable structure of the carbocyanines appears to be:



In the case of Pinacyanol, R represents the ethyl radicle. There thus appear to be three types of cyanines, the true cyanines, the isocyanines, and a third type, at present unknown in the quinoline series, of which the carbocyanines are an example in which the :CH. group connecting the two quinoline nuclei has been replaced by the chain :CH.CH:CH.—F. M. R.

Quinocyanines. II. O. Fischer and G. Scheibe. J. prakt. Chem., 1919, **100**, 86—90.

BY the action of 4-phenylquinolylmethiodide on the Ψ-base of 2-methyl-4-quinolylmethiodide a red dyestuff is produced, which is identical with that previously obtained by treatment of the Ψ-base in ethereal solution with air and carbon dioxide (J., 1919, 199A), and is therefore 4.4′-diphenyl-Ψ-isocyanine. 4.4′-Diphenyl-6.6′-dimethyl-Ψ-isocyanine is obtained by the second method from 2.6-dimethyl-4-phenylquinolylmethiodide. The parent Ψ-isocyanine is prepared by the addition of potassium hydroxide in excess to a solution of 2-iodoquinolylmethiodide and quinaldylmethiodide in hydrochloric acid. (*Cf.* J.C.S., Jan.)—J. K.

"Furol Green." O. Fischer and L. Grahl. J. prakt. Chem., 1920, **100**, 159—167.

THE leuco-base of Furol Green may be obtained in 30% yield by the condensation of furfural with dimethylaniline in presence of zinc chloride, and is converted into the dyestuff by means of lead peroxide. "Furol Green Ae" is similarly obtained by the use of diethylaniline. These dyestuffs dye silk, cellulose, and wool a brilliant yellowish-green, but in the last case the fastness to light is only slight (*Cf.* J.C.S., Jan.).—J. K.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Methyl alcohol from lignin. E. Heuser and H. Schmelz. Cellulose Chemie, 1920, **1**, No. 6. Paper, Nov. 17, 1920, 25, 32, 50.

ALL the methoxyl groups of lignin are not removed by the bisulphite treatment of wood for the isolation of cellulose, nor by the hydrolysis of wood by dilute acids for the saccharification of the cellulose, whilst the lignin obtained as a by-product of Willstätter and Zechmeister's method of hydrolysis in the cold with concentrated hydrochloric acid (J., 1913, 822) still retains almost the entire methoxyl content of the original wood. This lignin by-product, containing on the average 12—13% of methoxyl, is therefore a valuable potential source of methyl alcohol. By dry distillation the greater part of the methoxyl groups is destroyed, but much more satisfactory results are obtained by hydrolytic methods. Distillation with dilute hydrochloric acid (5·7%) gave acetic acid 2·53%, acetone 0·13%, and methyl alcohol 2·50%. Steam distillation in presence of hydrochloric acid was less satisfactory,

giving acetic acid 0·47%, acetone 0·53%, and methyl alcohol 1·04%. By far the best results, approximately quantitative in respect to methyl alcohol, were obtained by heating for 2 hrs. with dilute hydrochloric acid under 5—6 atm. pressure, this process being repeated with the residue from the first treatment. The total yield of products was acetic acid 2·19%, acetone 0·73%, and methyl alcohol 14·83%. The demethylated residue gave only a faint turbidity with silver nitrate by Zeisel's test.—G. F. M.

PATENTS.

Flax; Retting ——. B. S. Summers. U.S.P. 1,360,329, 30.11.20. Appl., 2.12.18.

FLAX is steeped in a bath of retting liquor and the insoluble products only are removed from the bath. —A. J. H.

Bast fibres of mallows; Process for separating the ——. H. Küchenmeister. G.P. 325,886, 20.12.18.

MALLOW stalks are heated with alkaline liquors, the layers of bast fibres are stripped off, and the fibres separated and freed from mucilaginous and insoluble substances by a thorough washing. For *Althæa cannabina* 8%, and for *Sida alba* 4% caustic soda is used. Fibres to be used for fine fabrics should be boiled twice with alkali.—A. J. H.

Shrinking fabrics; Method for ——. W. Dahse. G.P. 325,797, 25.2.19.

THE fabrics are treated with strong caustic soda or other substances with a similar action, to which may be added substances which diminish the shrinkage, *e.g.*, glycol or glycerin.—A. J. H.

Cellulose; Manufacture of —— *from straw, wood, and other cellulose substances.* H. Oexmann. G.P. (A) 306,325, 31.7.17, and (B) 309,259, 25.5.18.

(A) BEFORE treatment with strong alkalis, the raw materials are treated with solutions of weak alkalis, *e.g.*, lime. 100 kg. of straw is boiled first with 400—600 l. of water and 5—6 kg. of quicklime, and then with 4 kg. of caustic soda. The product is equal to that obtained by using 9—10 kg. of caustic soda only. (B) The treatment with the weak or with the strong alkalis or both may be effected at a temperature below boiling point.—A. J. H.

Half-stuff for paper making, cellulose, artificial silk, etc.; Manufacture of ——. K. Scholz, B. P. von Ehrenthal, and M. von Halle. G.P. 325,918, 21.3.17.

FIBROUS material as hemp, bagasse, tobacco stalks, jute, bamboo, etc., is treated by the usual method employed in digesting flax by the sulphite process, except that the alkali content of the sulphite liquor is increased to three or four times the usual amount, and is then digested with alkali.—A. J. H.

Cellulose acetate; Manufacture of compositions, preparations, or articles having a basis of ——. H. Dreyfus. E.P. 154,334, 26.8.19.

ADDITIONAL aromatic sulphonamide compounds (*cf.* E.P. 132,283 and 133,353; J., 1919, 896 A; 1920, 14 A), having high boiling points and insoluble in water, which are suitable as solvents or the like in the manufacture of dopes, films, celluloid-like masses, artificial silk, etc., having a basis of cellulose acetate are: benzenemonomethylsulphonamide (b.p. about 180° C. at 1 mm.), benzenemethylethylsulphonamide (b.p. 170°—175° C. at 1—2 mm.), mixtures of *o*- and *p*-toluenedimethylsulphonamides (b.p. 133°—137° C. at 1 mm.), mixtures of *o*- and *p*-toluenemethylethylsulphonamides (b.p. 188°—189° C. at 1 mm.), mixtures of *o*- and *p*-toluenediethylsulphonamides (b.p. 136°—142° C. at 1 mm.), *o*-toluenedimethylsulphonamide (b.p. 148°—152° C. at 2 mm.), *o*-toluenediethylsulphonamide (b.p. 152°—155° C. at 2 mm.), mixtures of isomeric xylenedimethylsulphonamides (b.p. 150°—155° C. at 1 mm.), mixtures of isomeric xylenediethylsulphonamides (b.p. 148°—154° C. at 1 mm.), mixtures of isomeric xylenemethylethylsulphonamides (b.p. 155°—156° C. at 1 mm.). These products are all liquid at the ordinary temperature and form jellies on cooling. For some applications, these aromatic dialkylated sulphonamide derivatives are not so good as benzenemonomethylsulphonamide and the monoalkylated sulphonamides specified in E.P. 132,283 and 133,353 (*loc. cit.*). The new solvents may be employed with any usual solvents or substances such as triphenyl phosphate, tricresyl phosphate, and acid-neutralising aliphatic derivatives of urea which are liquid or have a low melting point.—A. J. H.

Cellulose-ester composition. J. M. Kessler, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,360,759, 30.11.20. Appl., 19.6.20.

THE composition consists of nitrocellulose and an acetin free from mono-acetin and free acetic acid. —A. J. H.

Paper or other materials in sheet form; Apparatus for drying ——. O. Minton. E.P. 154,120, 26.3.20.

PAPER is dried by passing it without tension through a liquid seal into a vacuum chamber, over numerous rollers, some of which are immersed in a heated neutral fluid, and out through the same or a different liquid seal. Mercury may be used for the sealing liquid and for the heated neutral fluid. Paper having "cockled" effects may also be produced by this method, and the drying temperature may be low or high.—A. J. H.

[Sized] paper manufacture. R. Jennison and J. P. de Chanaz. E.P. 154,366, 9.9.19.

WOOD pulp or similar cellulosic material is treated with 20% of starch and 1 to 5% of caustic soda and beaten for ½ to 8 hrs. The caustic soda is neutralised by the addition of alum or other aluminium salt, the pulp is diluted with water, passed through a paper-making machine, and the paper dried. For transparent grease-proof paper, the paper web is incompletely dried, lightly calendered, and then friction-calendered until transparent. If more than 20% of starch be used, the strength and transparency of the paper are increased.—A. J. H.

Paper pulp; Process of making ——. R. H. McKee and A. A. Holmes. U.S.P. 1,360,658, 30.11.20. Appl., 24.5.19.

WOOD which contains resin is subjected to the action of liquid sulphur dioxide and is then converted into pulp by the usual methods.—A. J. H.

Asphalts [for sizing paper, fabrics, etc.]; Means for lowering the melting point of ——. Chem.-analyt. Lab. Schick & Horák. G.P. 325,780, 7.7.18.

THE melting point of asphalt is lowered by the addition of a terpene or an aliphatic or aromatic alcohol. For the impregnation of yarn, fabric, paper, cardboard, etc., asphalt containing 0·1—1% of fusel oil is suitable.—A. J. H.

Paper; Process of re-working old ——. J. M. Burby. E.P. 154,670, 22.8.19.

SEE U.S.P. 1,327,590 of 1920; J., 1920, 264 A.

Sulphite [-cellulose] liquor; Process for the production of valuable organic and inorganic substances from waste ——. R. W. Strehlenert. U.S.P. 1,361,506, 7.12.20. Appl., 10.5.17.

SEE G.P. 308,144 of 1917; J., 1918, 764 A.

Drying apparatus for varnished or painted paper. J. W. Wilson. E.P. 154,764, 15.10.19.

Concentrating sulphite-cellulose waste lyes. E.P. 154,355. *See* I.

Drying cylinders. E.P. 154,508. *See* I.

Fermentable sugars. U.S.P. 1,358,898. *See* XVIII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Cotton dyed with sulphur colours; After-treatment of —— [with copper sulphate]. A. S. Eichlin. Text. Col., 1920, 42, 777—778.

BLEACHED cotton was boiled with 30% solution of sodium sulphide containing sodium carbonate, thoroughly washed, and treated with 3% of copper sulphate and 1½% of acetic acid. It absorbed 0·04% of copper. Under similar circumstances, unbleached cotton absorbed 0·1% Cu. The following amounts of copper were fixed by cotton dyed with various sulphur dyes:—5% Sulphur Olive O. (Metz), 0·20% Cu; 10% Sulphur Olive O. (Metz), 0·36%; 5% Thiogene Blue B. (M.L.B.), 0·04%; 5% Thiogene Orange R. (M.L.B.), 0·04%; 5% National Sulphur Blue B.D., 0·06%; 5% National Sulphur Blue L., 0·06%; 5% Thiogene Yellow 5 G. conc., 0·17%; 5% Thiogene Gold Yellow A., 0·18%; 5% Thiogene Yellow G.G., 0·16%; 5% Thiogene Yellow G.H., 0·15%; 5% Thiogene Deep Blue 2 R.L. conc., 0·03%; 5% Thiogene Brown 3 R., 0·07%; 5% Katigen Yellow Brown (Bayer), 0·08% Cu.
—A. J. H.

PATENTS.

Fabrics; Method of dyeing and preserving ——. C. L. Cole (C. H. Cole extrix.). U.S.P. 1,361,139, 7.12.20. Appl., 6.6.17.

TEXTILE fabrics are treated with a solution of tannic acid and are subsequently immersed in a bath formed by suspending calcium carbonate in a solution of copper sulphate.—A. J. H.

Fireproofing and/or waterproofing treatment of materials. A. Arent. E.P. 132,813, 20.9.19. Conv., 20.9.18.

FABRICS are rendered fireproof by treatment with a solution of an antimony or bismuth salt (preferably antimony trichloride) in a volatile carbon chloride solvent such as carbon tetrachloride or chloroform, evaporating off the solvent, and hydrolysing the remaining antimony salt by exposing the fabric to steam or water. If the fireproofing solution contains a vulcanisable gum of the caoutchouc type or gutta-percha, the fabrics are also rendered waterproof. A solution of anhydrous antimony tri-iodide in carbon bisulphide may also be used.—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur and sulphuric acid; Preparation of —— from alkaline-earth sulphates. E. H. Riesenfeld. J. prakt. Chem., 1920, 100, 115—158.

THE reduction of kieserite by carbon does not take place solely according to the equation

$$2MgSO_4+C=2MgO+2SO_2+CO_2,$$

but is at least partly represented as follows:—

$$MgSO_4+C=MgO+SO_2+CO,$$

because sulphur is always found in the residue when less than one atomic proportion of carbon is employed. The best results are obtained with the proportion 1:1 at 750°—850° or 1·5:1 at 950° C., when the sulphur is almost entirely converted into sulphur dioxide, with a little free sulphur. Greater proportions of carbon do not produce the favourable effect which might be expected. The reduction of gypsum and anhydrite by carbon takes place fairly rapidly from 700° C. upwards approximately according to the equation $CaSO_4+3C=CaS+CO_2+2CO$. Strontium and barium sulphates behave similarly. The equilibrium $CaS+H_2O+CO_2 \rightleftarrows CaCO_3+H_2S$ cannot be utilised for the disposal of the calcium sulphide obtained as above, since temperatures, *e.g.*, 700° C., at which it is sufficiently rapidly attained, very largely favour the formation of calcium sulphide. At 800°—1000° C. the reaction, $CaSO_4+CH_4=CaS+CO_2+2H_2O$, would probably permit complete reduction, if sufficiently prolonged, but below 800° C. dehydration alone occurs. Above 1100° C. some oxide is produced, probably according to the equation, $CaS+H_2O=CaO+H_2S$, and, as would therefore be expected, excess of steam at 1200°—1300° C. favours complete removal of the sulphur. This is, however, obtained almost entirely as sulphur dioxide and sulphur—chiefly the latter when only a slight excess of steam is used—partly owing to dissociation of hydrogen sulphide and partly owing to its reaction with steam. The amounts of sulphur dioxide and sulphur produced by the action of steam on calcium sulphide agree with the above statement. Further, calcium sulphate is converted directly into the oxide by treatment with water and steam at 1200°—or, more than six times more rapidly, at 1300°. Owing to the reduction of sulphur dioxide by carbon monoxide and hydrogen, sulphur is the chief product, only 50% of sulphur dioxide being obtained even when 850 times the theoretical proportion of steam is employed.—J. K.

Nitrogen in nitrates and nitrites; Determination of —— by copper-magnesium. T. Arnd. Z. angew. Chem., 1920, 33, 296—298.

IN a method described previously by the author (Z. angew. Chem., 1917, 30, 169), in which the nitrite or nitrate is reduced to ammonia by distilling with copper-magnesium alloy and magnesium chloride solution, an excess of the latter is required to prevent the interference of sulphates and other salts. At least 2·5 g. of the alloy must be used for each 0·5 g. of nitric nitrogen present.—W. P. S.

Potash in wood ashes and treater dust; Modified method for the determination of water-soluble ——. H. D. Haskins. J. Assoc. Off. Agric. Chem., 1920, 4, 82—84.

FRESHLY made dry ashes and dry treater dust will yield appreciably more water-soluble potash if allowed to remain in contact with water for several hours previous to extraction with boiling water. In the case of ash products which contain a considerable amount (12—30%) of water very little advantage results from the preliminary soaking in water.—W. G.

Potassium platinichloride; Composition of ——. A. Vürtheim. Chem. Weekblad, 1920, 17, 637—640.

POTASSIUM platinichloride reaches constant weight after drying for 2 hrs. at 150° C., but this treatment is not enough to remove all the enclosed water, and precipitation from aqueous solution by means of alcohol and drying at 110° C., gives results which agree better with the formula K_2PtCl_6. The accuracy of the accepted atomic weight of platinum is questioned. (*Cf.* J.C.S., Jan.)—S. I. L.

Leucites and leucitic minerals; Analysis of ——. G. Tommasi. Ann. R. Staz. Chim.-Agrar. Sperim., 1917-1919, II., 9, 95—106.

1·25 GRAM of the leucite or leucitic mineral, ground

to an impalpable powder, is treated in a covered beaker with about 45 c.c. of hydrochloric acid and 5 c.c. of nitric acid, first for 2 hrs. on a water-bath and then for 20 mins. on a sand-bath. The insoluble silicious matter is then estimated in the ordinary way, the alkalis are isolated as usual, and the potassium estimated by the perchlorate method. This procedure gives results agreeing with those obtained when the mineral is attacked by hydrofluoric acid or by ammonium chloride and calcium carbonate according to the Lawrence Smith method.—T. H. P.

Electrolytes; Flocculating power of ——. (Opacity number.) N. Bach. J. Chim. Phys., 1920, **18**, 46—64.

FROM experiments on colloidal ferric hydroxide and arsenic trisulphide, the author concludes that the power of electrolytes to effect the flocculation of colloidal sols may be determined accurately by dropping the electrolyte solution at intervals of precisely 20 secs. into a measured volume of the sol contained in a glass cylinder of 20 c.c. capacity and observing the amount of electrolyte required to produce a definite turbidity. The opacity number is the inverse of the amount of electrolyte required; that of potassium chloride is taken as unity. The relative opacity numbers of two electrolytes depend solely on the nature of the colloidal sol, and may even be independent of the chemical nature of the sol. The flocculating powers of the alkali-ions and halogen-ions decrease in the following order: Cs, Rb, NH_4, K, Na, Li and Cl, Br, I. Other things being equal, any ion will flocculate an oppositely charged sol or protect a similarly charged one in proportion to the amount of charge on the ion. The flocculating power is much greater than the protective power. In the case of halogen ions, the differences between the potentials required to discharge them are proportional to their flocculating power. When various electrolytes have a common ion their flocculating powers are additive. Colloidal sols are extremely sensitive to traces of polyvalent impurities. Divalent ions have about 30 to 40 times the flocculating power of univalent ions, and trivalent ions have about 12 times the flocculating power of divalent ions.—A. B. S.

Cupric hydroxide; Solubility of —— in concentrated sodium hydroxide solution. E. Müller. Z. angew. Chem., 1920, **33**, 303—305.

CONCENTRATED sodium hydroxide solution dissolves cupric hydroxide, yielding a violet-blue, unstable solution; in the case of 48% sodium hydroxide solution the copper content may amount to about 3%. The author discusses the matter from a physico-chemical point of view, and concludes that the solution of the copper hydroxide is due to the formation of complex ions.—W. P. S.

Carbonyl chloride; Preparation and physical properties of ——. R. H. Atkinson, C. T. Heycock, and W. J. Pope. Chem. Soc. Trans., 1920, **117**, 1410—1426.

CARBONYL chloride is most conveniently prepared in quantity by the method, originally described by Paternò (Gaz. Chim. Ital., 1878, **8**, 233), of passing chlorine and carbon monoxide over charcoal. The wood charcoal used in the Army box respirator proved the most efficient for the purpose, effecting complete and rapid conversion of the mixed gases into carbonyl chloride at ordinary temperatures, 50° C. below that at which it began to show catalytic activity towards a mixture of hydrogen and chlorine—a fact of importance when carbon monoxide containing hydrogen is used. Dissociation of carbonyl chloride begins at temperatures above 200° C.; at 309° C. it amounts to 5·61%, and at 503° C. 55—56%. The vapour pressure of carbonyl chloride was determined between 100° C. and —183° C. The vapour pressure curve begins to fall rapidly only below −40° C., hence considerable losses will occur in the manufacture unless the effluent gas is either cooled below this temperature or scrubbed with a suitable solvent, such as toluene, xylene, or chlorobenzene, in which the gas is readily soluble. Carbonyl chloride freezes at −126° C., its sp. gr. at 0° C. is 1·435, and the mean coefficient of cubical expansion between −79° and +49·9° C. is 0·00177.—G. F. M.

Carbon dioxide; Preparation of pure ——. R. C. Farmer. Chem. Soc. Trans., 1920, **117**, 1446—1447.

THE difficulty of preparing carbon dioxide free from air, even when all the solutions used in making the gas are previously boiled, is overcome by using solutions of potassium bicarbonate and sulphuric acid, each of which is freed from air by bubbling carbon dioxide through it before the two are brought together. A convenient generator for the purpose consists of a Woulff's bottle, into two necks of which pear-shaped funnels with long wide stems, containing the respective solutions, are fitted, a narrow extension passing down to dip just beneath the surface of a layer of mercury in the bottom of the bottle for the purpose of preventing back diffusion. A branched gas-delivery tube is fitted into the third neck of the Woulff's bottle from one arm of which the gas is drawn off as required through a glass stop-cock, whilst the other arm leads to the top of the pear-shaped funnels, and a tube passed down the stems of each so as to bubble the gas through the columns of liquid. The flow of the reagent solutions into the bottle is automatically regulated by the gas delivery stop-cock; when this is shut, the back pressure prevents any further quantity of solution entering the bottle. Once started the apparatus need never be disconnected, and spent liquor can be drawn off by means of a glass tube passing through the neck to just above the surface of the mercury.—G. F. M.

PATENTS.

Acids [e.g., nitric acid]; Production of ——. C. L. Tayntor. U.S.P. 1,361,416, 7.12.20. Appl., 29.11.19.

SULPHURIC acid is added to sodium nitrate in a number of generating stills, delivering into a common expansion chamber, which in turn is connected with several "bleachers" and condensers arranged in parallel, and communicating with a common scrubbing tower.—C. I.

Potassium sulphate and hydrochloric acid; Manufacture of ——. Fabr. de Prod. Chim. de Thann et de Mulhouse. E.P. 154,111, 27.2.20. Conv., 4.12.19. Addn. to 137,296 (J., 1920, 516 A).

IN the process described in E.P. 137,519 (J., 1920, 689 A), the three stages of desiccation, heating at 300° C., and heating at 700°—800° C., may take place in a single direct-flame furnace, or in a compound direct-flame and muffle-furnace; instead of operating in three stages the process may be conducted progressively in a single furnace, care being taken to keep the mass solid and porous. Aqueous sulphuric acid containing more than 70—72% SO_3 may be used, the proportions being such as to retain the pulverulent nature of the mixture. —W. J. W.

Sulphate of ammonia; Manufacture of —— and apparatus therefor. N. Wilton. E.P. 154,328, 26.8.19.

WET ammonium sulphate from the saturator is thrown into a tilting vessel fitted with a lid and

mounted on trunnions, and having a perforated false bottom. The adherent mother-liquor and most of the free acid are then removed by blowing in dry steam at 70—80 lb. pressure, with or without air. The remaining free acid may be neutralised by introducing ammonia gas. The vessel is tilted to the side opposite to the saturator to remove the dried salt.—C. I.

Soda; Process of manufacturing ——. T. Nishigawa. U.S.P. 1,359,097, 16.11.20. Appl., 30.9.19.

In the ammonia-soda process the mother liquor from which sodium bicarbonate has been separated is treated with sodium chloride, and then cooled and treated with sufficient ammonia gas to convert the bicarbonates still in solution into normal carbonates, whereupon ammonium chloride separates out. The residual mother liquor is again used as brine for the production of sodium bicarbonate. —J. H. L.

Manganese-containing bodies [manganese chloride]; Producing ——. A. A. Wells, Assr. to National Carbon Co. U.S.P. 1,359,640, 23.11.20. Appl., 29.6.18.

The spent mixture from dry batteries is treated with hydrochloric acid, carbonaceous material is filtered off, and the filtrate boiled to drive off chlorine and excess acid. The solution is digested with freshly precipitated manganese carbonate to precipitate iron compounds and filtered. —J. S. G. T.

Magnesium chloride and the like; Method of making ——. E. O. Barstow, Assr. to The Dow Chemical Co. U.S.P. 1,359,782, 23.11.20. Appl., 1.3.18.

Slaked dolomitic lime is treated with sulphur dioxide and carbon dioxide, and calcium chloride is added to the product.—W. J. W.

Phosphate; Process for the manufacture of ——. G. R. Brobst. U.S.P. 1,360,248, 23.11.20. Appl., 26.3.19.

A mixture of phosphate rock, felspar, limestone, iron ore, furnace slag, and sodium carbonate is calcined, and the volatile products are collected with the aid of a spray of dilute ammonia.—W. J. W.

Carbonyl chloride; Process of making ——. S. Peacock. U.S.P. 1,360,312, 30.11.20. Appl., 29.10.19.

Carbonyl chloride is produced by passing a mixture of air and chlorine over heated carbonaceous material.—D. F. T.

Molybdenum compounds; Production of ——. G. Richter, Assr. to The Chemical Foundation, Inc. U.S.P. 1,360,581, 30.11.20. Appl., 12.7.17. Renewed, 19.4.20.

A material containing molybdenum is treated with a sulphurising agent and water, and the resulting solution treated with a desulphurising agent. —A. B. S.

Permanganate; Process for electrolytic production of ——. R. E. Wilson and W. G. Horsch. U.S.P. 1,360,700, 30.11.20. Appl., 29.11.18.

An anode containing manganese is employed in the continuous electrolysis of an electrolyte consisting of a solution of an alkali carbonate as anolyte and a caustic alkali solution as catholyte. The solution of alkali carbonate is added continually and the electrolyte is kept in circulation.—J. S. G. T.

Oxides in neutral water solutions; Electrolytic production of ——. S. Fry. U.S.P. 1,361,041, 7.12.20. Appl., 13.11.16.

Hydrated oxides are produced direct from metals by employing the metal as anode in the electrolysis of an aqueous solution of a salt of sodium, potassium, ammonium, or calcium, of such concentration that the metal is deposited as hydrated oxide. —J. S. G. T.

Acid ammonium phosphate; Process for the preparation of ——. Gewerkschaft ver. Constantin der Grosse. G.P. 307,093, 20.5.14.

Ammonia is passed into a solution of phosphoric acid of 30° B. (sp. gr. 1·26) until the specific gravity rises to 1·28 (32° B.), whereby acid ammonium phosphate is precipitated.—A. R. P.

Combustion of nitrogen; Process for ——. *Process for the separate preheating of reacting gases, especially for combustion of nitrogen.* Gewerkschaft des Steinkohlenbergwerks "Lothringen," and M. Kelting. G.P. (A) 325,800, 28.10.19 (Addn. to 324,264; J., 1920, 783A), and (B) 326,228, 31.12.19.

(A) The finely divided carbon added to the reacting gases in the combustion of nitrogen in a hydrogen or carbon monoxide flame is introduced into the gases by passing them through a preheater over heated carbon compounds, *e.g.*, fused anthracene. (B) The reacting gases (heating gas and air) are passed in layers through the narrow channels of a preheater into the combustion chamber. The hot issuing gases from the latter serve to preheat further quantities of the gases.—A. R. P.

Kieserite; Separation of —— *from a mixture of potassium chloride and kieserite suspended in a liquid.* Kaliwerke Grossherzog von Sachsen A.-G., and K. Hepke. G.P. 326,156, 9.4.18.

The liquid in which a mixture of kieserite and potassium chloride is suspended is passed through an open channel or closed tube into a long, deep, and narrow trough provided with a conveyor belt running in the opposite direction to the flow of liquid. The kieserite alone settles. The finer and slimier the kieserite is, the longer and deeper the trough should be.—A. R. P.

Salts of trivalent chromium; Process for the preparation of ——. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 326,268, 17.11.18.

Waste gases containing sulphur dioxide, *e.g.*, the issuing gases from the manufacture of sulphuric acid, are passed through a solution of chromic acid or an acidified solution of its salts.—A. R. P.

Chlorides; Process and apparatus for electrolytic decomposition of ——. B. Cataldi. E.P. 127,255, 20.5.19. Conv., 20.5.18.

See U.S.P. 1,336,281 of 1920; J., 1920, 405 A.

Nitrogen; Method and apparatus for the fixation of atmospheric ——. J. S. Island. E.P. 154,356, 3.9.19.

See U.S.P. 1,316,445 and 1,317,705 of 1919; J., 1919, 819 A, 901 A.

Sulphate of ammonia; Manufacture of neutral ——. P. Parrish and W. A. M. Valon, Assrs. to South Metropolitan Gas Co. U.S.P. 1,360,785, 30.11.20. Appl., 11.8.19.

See E.P. 141,819 of 1919; J., 1920, 447 A.

Hydrogen; Manufacture of ——. S. W. Bray and I. H. Balfour, Assrs. to British Oxygen Co. U.S.P. 1,360,876, 30.11.20. Appl., 31.3.20.

See E.P. 144,751 of 1919; J., 1920, 571 A.

VIII.—GLASS; CERAMICS.

Glass; Annealing temperature of ——. F. Weidert and G. Berndt. Z. tech. Phys., 1920, **1**, 51—58. Chem. Zentr., 1920, **91**, IV., 642—643.

THE annealing temperature of a glass may be determined by measuring the difference between the refractive indices of the ordinary and extraordinary rays of light passed through the glass before and after cooling from various temperatures between 200° and 600° C., and plotting this difference against the temperature of the glass before cooling. The graph so produced is a hyperbolic curve with a sharp bend at the annealing temperature. This point is independent of the size of the specimen and of the rate of cooling within wide limits. The deformation temperature (*i.e.*, the temperature at which a 25-mm. cube set on one of its corners on a specimen of the polished glass and half embedded in kieselguhr makes an appreciable impression on the glass after 6 hrs.' heating) is about 30° C. below the temperature at which two plates of the glass permanently cohere, and 40°—50° C. higher than the annealing temperature of flint glasses and 70°—100° C. higher than the annealing temperature of crown and barium glasses made at the Sendling works. The deformation temperature of a glass is characteristic, but is also a function of the duration of the heating and of the size of the specimen. —A. B. S.

Lead glasses; Composition of ——. R. J. Montgomery. J. Amer. Ceram. Soc., 1920, **3**, 900—912.

THIRTY-TWO lead glasses are discussed, the compositions being expressed as xRO,1SiO$_2$, x lying between 0·30 and 1·22, and the refractive index varying from 1·51 to 1·95. The influence of RO content and PbO in RO content on refractive index and dispersive power are shown graphically. A linear relationship connects the refractive index and the PbO in the RO content. Some lead glasses contain free silica, others consist of lead silicates containing no alkali but having an excess of lead oxide, which the lead silicate must take into solution to give a glass.—H. S. H.

Clays of low plasticity and strength; Effect of wet grinding, screening, electrolytes, and dextrin on ——. H. W. Douda. J. Amer. Ceram. Soc., 1920, **3**, 885—892.

THE dry strength of clays is increased by wet grinding for 2 hrs., additional increases being obtained by adding 1% of caustic soda and wet grinding, screening through a 150-mesh sieve, or adding 1% of dextrin. The plasticity of th clays is increased by wet grinding, screening, and the addition of 1% of dextrin. Caustic soda causes the clay to become tougher and more difficult to mould. The drying shrinkage is increased, the apparent density decreased, and the water of plasticity increased by wet grinding. The fineness of grain of the clay is increased by wet grinding and further increased by adding 1% of caustic soda. The strength of the clays after burning to cone 2 is increased by the above treatments.—H. S. H.

Heat transmission of brick and high-temperature insulating materials. R. A. Horning. J. Amer. Ceram. Soc., 1920, **3**, 865—876.

A TEST-PIECE was heated electrically by coils of wire in contact with it. The cool end rested on a water-cooled plate, baffles causing the water to flow in a zigzag path across the plate. Only the heat passing through the central part of the heated area (about 1/9 of the whole area) was measured, the quantity being obtained from the current and fall of voltage in the central heating coil. The temperature of the hot face was given by a thermo-couple embedded in it, and the average temperature of the water entering and leaving the cooling plate gave the temperature of the cool face. By replacing the cooling plate by electrically heated coils of wire, a constant difference of temperature was maintained between the faces and the heat transmission measured for different temperatures of the hot face. The materials examined, arranged in order of decreasing thermal conductivity, were magnesia brick, silica brick, vitrified building brick, firebrick, re-pressed burned kieselguhr brick, natural kieselguhr brick perpendicular to grain, "nonpareil" insulating brick, and "nonpareil" high-pressure block. The conductivities increased with rise of temperature up to 1500° F. (815° C.).—H. S. H.

Vermilion colour [for glazes] from uranium. C. F. Binns and F. Lyttle. J. Amer. Ceram. Soc., 1920, **3**, 913—914.

A BRIGHT vermilion colour is given by a glaze corresponding approximately to the mixture: red lead 57%, felspar 20%, zinc oxide 2%, flint 12%, uranium oxide 9%, and fired to cone 04 in closed saggars. The amount of uranium oxide present must not vary greatly. Some difficulty is experienced in protecting the uranium oxide from reducing influences.—H. S. H.

PATENTS.

Glass; Means for obtaining —— *from a furnace.* The Empire Machine Co., Assees. of B. D. Chamberlin. E.P. 138,895, 9.2.20. Conv., 15.11.15.

A GLASS furnace having a suitable orifice through which a stream of glass may flow is provided immediately beneath the orifice with a shearing mechanism through which a cooling medium flows. To prevent "scarring," due to chilling of the glass, the orifice and shearing mechanism are enclosed in a supplemental heating chamber, so that the severed and chilled ends of the glass are immediately reheated. By varying the temperature in the supplemental chamber the rate of flow of the glass and the cross-sectional area of the severed charge are controlled.—H. S. H.

Glass; Impts. in and apparatus for the manufacture of ——. A. Ferguson. E.P. 154,251, 28.5.19.

GLASS-MAKING materials are fed into a trumpet-shaped melting chamber with a dome-shaped top. Gas and air are forced in a tangential direction into the upper part of the melting chamber and by their whirling movement form a vortex into which fall the particles of glass-making materials. The materials react, are driven on to the walls, and drop or drain into the tank furnace placed below, and are refined there by the heat from the gases entering the tank furnace from the melting chamber. Waste gases may be used to preheat the gas and air or the glass-making materials.—H. S. H.

Glass-annealing leer [lehr]. E. E. Milner and W. J. Lytle, Assrs. to H. L. Dixon Co. U.S.P. 1,361,604, 7.12.20. Appl., 1.8.19.

A LEHR is provided with several groups of heating flues surrounding the major portion of the annealing chamber. In one group of flues the heating medium passes in opposite directions in adjacent flues, whilst in another group the heating medium travels upwards and in the same direction in adjacent flues. The upper portion and sides of the lehr are covered with heat-insulating material of progressively decreasing thickness towards the rear end of the annealing chamber.—A. B. S.

Basic refractory composition and process of making the same. H. P. Bassett. U.S.P. 1,360,355, 30.11.20. Appl., 15.10.19.

THE composition consists of a mixture of magnesian limestone, iron, a compound of silicon, and sodium chloride.—A. B. S.

Kiln; Combined muffle and open tunnel ——. P. d'H. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. (A) 1,360,625 and (B) 1,360,626, 30.11.20. Appl., (A) 26.1.20; (B) 28.5.19. (B) Renewed 18.5.20.

(A) A TUNNEL kiln has an elongated kiln chamber formed of two sections placed end to end. A muffle extends longitudinally in one section and communicates with the other section at the junction of the two sections. The burning gases and products of combustion flow longitudinally through the interior of the muffle and the interior of the other kiln section. (B) In a tunnel kiln with a kiln chamber formed of two sections as in (A), a combustion chamber, separate from the kiln chamber, extends longitudinally in one of the sections and communicates with the other section at the junction of the two sections. Air and fuel enter the combustion chamber at the end remote from the other section. The products of combustion are drawn from the combustion chamber through the other section.—H. S. H.

Dryer for clay or ceramic products. I. M. Justice, Assr. to The Manufacturers' Equipment Co. U.S.P. 1,360,645, 30.11.20. Appl., 3.5.19.

THE dryer comprises drying tunnels with fuel passages extending beneath and means for moving the ware through the tunnels. Air enters through inlets placed at the receiving ends of the drying tunnels and is gradually heated as it passes through the dryer. The fuel tunnels and the drying tunnels communicate with a stack.—H. S. H.

Enamel coat on steel; Process for producing a single white ——. S. Rieser, Assr. to The New England Enameling Co. U.S.P. 1,360,317, 30.11.20. Appl., 21.11.16.

IN the production of white enamel on steel the frit is ground with water and clay, and a portion only of the soluble enamelling constituents removed.
—H. S. H.

Enamels; Process for making ——. G. Rupprecht, Assr. to The Chemical Foundation, Inc. U.S.P. 1,360,585, 30.11.20. Appl., 4.6.17.

ENAMELS are made by subjecting the raw materials to the direct action of a flame, the molten substance being supported on an unmolten mass of the same raw materials and prevented from coming into contact with foreign matter.—A. B. S.

Glass surfaces; Decorating ——. K. Warga. E.P. 148,304, 9.7.20. Conv., 16.8.16.

SEE U.S.P. 1,283,606 of 1918; J., 1919, 76 A.

Glass; Apparatus employed in manufacture of hollow articles of ——. A. Ferguson. E.P. 154,252, 28.5.19.

Glass; Delivery of molten —— [*to moulds*]. British Hartford-Fairmont Synd., Ltd. From Hartford-Fairmont Co. E.P. 154,861, 25.6.20.

IX.—BUILDING MATERIALS.

Lime plaster; "Popping" (unsoundness) of ——. W. E. Emley and C. H. Bacon. J. Amer. Ceram. Soc., 1920, 3, 877—884.

THE "popping" of a lime plaster is caused by grains of a material which hydrates slowly and expands as it hydrates. Such material may be a compound of calcium with silica, alumina, or iron, or an incompletely oxidised salt of iron, and may come from the ash of the fuel or from impurities in the limestone or sand. By rejecting all lumps of lime encrusted with vitreous material, screening the hydrated lime through a No. 48 sieve, and soaking all lime putty overnight before using it as a plaster, all danger of "popping" is removed. The sand should not contain more than 1% of sodium and magnesium chlorides.—H. S. H.

PATENTS.

Exotic woods; Process for reducing or softening the colours of ——. P. E. Simon. E.P. 141,052, 30.3.20. Conv., 9.4.18.

THE wood is immersed in acid, preferably nitric acid (sp. gr. 1·04—1·26), then dried rapidly at the maximum temperature which it can endure without charring, and afterwards well rinsed in water. Rosewood veneers are immersed for ½ hr. in oxalic acid solution at 80° C., rinsed in water at the same temperature, and the moist wood treated as described above. A mixture of hydrochloric and nitric acids of sp. gr. 1·02—1·06 at 30°—40° C. may be used instead of nitric acid if a redder colour is desired. To lessen the visibility of the grain a preliminary immersion for 24 hrs. in 90% alcohol followed by hot rinsing is recommended. Amaranth wood is immersed for 15—30 mins. in water at 60°—80° C. and then in a nitric acid bath. The treated wood may be scraped without change of colour.—A. B. S.

Glaze on building materials, in particular cement; Method of producing a cold ——. K. Friedrich. E.P. 154,236, 27.3.18.

A GLAZE is produced on concrete, stone, brickwork, and the like by applying a mixture of 8 pts. of finely sifted Portland cement, 1 pt. of colouring matter, 10 pts. of water, and 1 pt. of bituminous substance prepared by dissolving 15 pts. of sodium carbonate in 60 pts. of water and adding 20 pts. of asphaltum (freed from oils of b.p. below 270° C.), shaking the mixture to emulsify it, and stirring in 5 pts. of powdered barium peroxide.—A. B. S.

Shaft furnaces especially applicable to the manufacture of cement. F. W. Bakema. E.P. 154,510, 8.5.20.

THE lower part of a shaft kiln for burning Portland cement is fitted with a perforated rotating helix which acts as a grate. The helix may be supported axially, or partly axially and partly by attaching its circumference to a rotating drum, to provide a better support.—A. B. S.

Bricks; Process for the manufacture of light —— *from freshly mined kieselguhr.* W. Bünte. G.P. 326,116, 21.10.19. Addn. to 324,375.

FRESHLY mined kieselguhr containing up to 50% of moisture is ground together with cheap binding materials, *e.g.*, gypsum or lime, or both, instead of cement. Sand or similar substances may also be added.—A. R. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Nickel steels; Cause of the instability of —— *and its elimination.* C. E. Guillaume. Comptes rend., 1920, 171, 1039—1041.

THE instability of nickel steels is shown to be due to the presence of carbon and the consequent formation of cementite, the slow transformation of which is capable of producing the phenomena observed (*cf.* J., 1899, 768). The stabilisation of nickel steels may thus be connected with the absence of cementite. It is shown that the addition to nickel steel of a sufficient amount of a metal such as chromium, tungsten, or vanadium, which has an affinity for carbon greater than that of iron, renders such steels far more stable, but a slight residue of

cementite always remains. To arrive at complete stability it seems necessary to add to the alloy a considerable excess of the third metal.—W. G.

[Gold;] Influence of soluble silica and calcium salts on precipitation [of —— from cyanide solutions]. J. H. Johnson. J. Chem. Met. Soc. S. Africa, 1920, **21**, 58—59.

THE presence of colloidal silica in the solutions from sand clarifiers led to the formation of a deposit on the zinc in the precipitation boxes and of a scum at the head and between compartments of the boxes. The deposit, which prevented the precipitation of gold by the zinc, and the scm were found to consist mainly of calcium carbonate and hydrated silica, probably due to excessive alkalinity of the solutions in the circuit.—A. R. P.

Silver; Recovery of —— from manganese-silver ores. J. A. Carpenter. Eng. and Min. J., 1920, **110**, 898—902.

MANGANESE-SILVER ore from which the silver cannot be obtained by any of the ordinary methods owing to its association with refractory minerals, gives good yields if heated to 1000° C. in a current of air with sodium chloride. Silver, copper, lead, and gold chlorides are volatilised and collected in a Cottrell plant with a yield of 95—99%. Alternatively, the ore may be heated with the salt to about 900° C. for 30—45 mins., whereby only small quantities of the precious metals are volatilised, the remainder being leached out by cyanide in the usual way. The extraction is exceedingly rapid and very complete and the cyanide consumption low. The cost of the processes should not be prohibitive; 15—25 galls. of fuel oil is required per ton for the first process and much less for the second, while the consumption of salt varies from 50 to 180 lb. per ton.—A. R. P.

Copper losses in slags. F. E. Lathe. Eng. and Min. J., 1920, **110**, 1076—1080.

THE amount of oxidised copper present in slags from copper smelting is determined by digesting 2 g. of the slag, ground to pass 200-mesh, with 100 c.c. of a 3% solution of sulphur dioxide and 10—15 c.c. of hydrofluoric acid in a stoppered bottle for several days with occasional agitation. The solution is filtered, the filtrate boiled to expel sulphur dioxide, and the copper precipitated as sulphide and determined electrolytically. The estimation of the sulphide copper in slags by digestion with silver nitrate solution is unreliable, as the reagent dissolves a small part of the oxidised copper and leaves part of the sulphide copper unattacked. Tables are given showing the proportion of copper existing in the two states in blast furnace, reverberatory, and converter slags from several American smelters, and suggestions are given for possible improvements in the technique of slag settling.—A. R. P.

Roasted blende; Determination of the sulphide sulphur in ——. M. de Keghel. Rev. Chim. Ind., 1920, **29**, 285—288. Chem. Zentr., 1920, **91**, IV., 659—660.

DISTILLATION of the material with stannous chloride and absorption of the evolved hydrogen sulphide in a solution of zinc or cadmium acetate and iodine in potassium iodide gives unreliable results. The following procedure is therefore recommended: The finely divided sample is heated with a solution of stannous chloride in hydrochloric acid and the evolved hydrogen sulphide driven, by means of a current of carbon dioxide, through a series of three absorption flasks, the first of which contains dilute acetic acid and the other two, cadmium acetate solution. When the reaction is complete, the contents of the latter two flasks are boiled for 10 mins. and allowed to cool for 15 mins. in a current of carbon dioxide. The liquid is then transferred to a larger flask, boiled to expel carbon dioxide, cooled, diluted largely, a measured volume of standard iodine added, and the excess titrated as usual. Addition of a small quantity of ammonium carbonate when diluting, increases the sensitiveness of the end-point. Stoppers of vulcanised rubber must not be used in any part of the distillation apparatus.—A. R. P.

Lead [in ores]; Determination of —— as chromate. C. W. Simmons, J. R. Gordon, and H. C. Boehmer. Canad. Chem. J., 1920, **4**, 139.

THE ore is dissolved in a mixture of hydrochloric and nitric acids, the solution evaporated to a volume of 8 c.c., and ammonia added until a permanent precipitate of hydroxide is obtained; this is dissolved by adding an excess of acetic acid and 3 g. of ammonium acetate, and 10 c.c. of 10% potassium chromate solution is then added. The mixture is kept warm for 5 mins., the precipitated lead chromate collected, dissolved in a mixture of 25 c.c. of concentrated hydrochloric acid and 75 c.c. of water, the solution diluted to 200 c.c., treated with 1 g. of potassium iodide, and the liberated iodine titrated with thiosulphate solution.
—W. P. S.

Metals; Solubility of —— in acids containing formaldehyde. R. C. Griffin. J. Ind. Eng. Chem., 1920, **12**, 1159—1160.

THE solvent action of dilute sulphuric acid (10° B., sp. gr. 1·074) and hydrochloric acid (1:1) on wrought iron, cast iron, and steel is decreased very considerably by the addition of 1% of formaldehyde to the acids, the corrosion loss being diminished 65—98%. The effect is less marked in the case of 10% nitric acid and also in the case of other metals, such as brass, tin, nickel, etc.—W. P. S.

Hydrogen peroxide; Use of —— in metal tinting. H. Krause. Metall, 1920, 229—230. Chem. Zentr., 1920, **91**, IV., 715.

HYDROGEN peroxide is of no use for tinting smooth polished metal surfaces, but for unpolished surfaces, especially those that have been coloured by other reagents, *e.g.*, a strong solution of potassium chlorate containing ammonium nitrate, or, for darker tints, potassium permanganate, concentrated solutions of hydrogen peroxide (perhydrol) are useful for toning down the colours, for which purpose the reagent is applied with a fine brush and develops generally a bright brown colour.—A. R. P.

Bismuth in ores. Schoeller and Waterhouse. *See* XXIII.

PATENTS.

High-speed steel; Treating ——. C. A. Whitmyre, Assr. to General Electric Co. U.S.P. 1,359,851, 23.11.20. Appl., 2.8.19.

THE steel is hardened by heating to 1275°—1300° C., then quenching at 600°—650° C.—J. W. D.

Steel; Process of improving the machining properties of ——. M. T. Lothrop, Assr. to The Timken Roller Bearing Co. U.S.P. 1,360,551, 30.11.20. Appl., 20.10.19.

ROLLED steel is hot worked at a temperature above 2300° F. (1260° C.) to improve its machining properties.—T. H. Bu.

Iron and steel; Manufacture of —— directly from the ore, and apparatus therefor. L. P. Basset. U.S.P. 1,360,711, 30.11.20. Appl., 24.10.18.

THE ore is reduced by means of a carbonaceous reducing agent, and the metal melted by a very hot flame producing substantially only carbon monoxide, with exclusion of carbon dioxide and water vapour.—J. S. G. T.

Steel; Method for manufacturing ——. D. R. Knapp. U.S.P. 1,361,589, 7.12.20. Appl., 20.1.20.

AFTER melting and refining a charge of steel, a relatively small portion of the charge is removed and a relatively small portion of cold charge added to the molten bath.—T. H. Bu.

Alloys of copper and zinc; Electro-deposition of ——. S. O. Cowper-Coles. E.P. 154,108, 24.2.20.

CATHODE plates or articles to receive the deposit are placed in an electrolyte consisting of a solution of a salt or compound of one of the metals, and a salt or compound of the other metal is added continuously, the electrolyte being rapidly agitated with propellers. A test-piece of thin metallic ribbon is passed continuously through the electrolyte and is slowly wound up by suitable mechanism in order to facilitate control of the working conditions.
—J. W. D.

Electric [smelting] furnaces. A. M. Erichsen. E.P. 154,444, 25.11.19.

IN electrical smelting furnaces provided with resistance bars above the charge, adjustable vents are provided by means of which a slight draught is created through the space above the charge. Deposition of condensed matter in the sleeves in the furnace walls through which the resistance bars pass is thus prevented and freedom of movement of the bars maintained. The charging hopper projects downwards through the heating bar grate, whereby preheating of the charge in the hopper is effected on both sides. The furnace may be mounted on wheels turning about the tilting axis of the furnace.—J. S. G. T.

Electrolysing a solution of nickel salt; Method for ——. C. Heberlein. E.P. 154,471, 8.8.19.

THE process is carried out in a cell of the type described in E.P. 141,766 (J., 1920, 456 A), comprising a series of electrolytic vats, each divided into a number of cathode compartments containing a similar number of stationary cathodes separated by electrolytic diaphragms from insoluble anodes arranged between the cathode compartments, the whole being immersed in a single anode compartment formed by the vat. The catholyte is fed in parallel, though the cathode compartments of one vat after the other, whereby uniform concentration and acidity are maintained in each compartment. The catholyte is prepared by dissolving nickel from ore, matte, etc., by means of acid until an acid liquor of the optimum acidity (0·1—0·4% of free acid) for electrolysis is obtained. A nickel salt solution is used as anolyte and circulates through the anode compartments in series. Circulation of catholyte and anolyte is continued until the acidity of the anolyte is such as to be incompatible with the maintenance of optimum acidity of the catholyte. Thereupon the anolyte is withdrawn and used for preparing fresh nickel salt solution of optimum acidity, whilst the catholyte is returned to the catholyte circulation in admixture with fresh nickel salt solution, so that a catholyte liquor of optimum acidity is obtained.—J. S. G. T.

Electrolysis [for deposition of metal in non-coherent form]. W. A. Adam, J. Stevenson, A. T. Mabbitt, and J. Fieldhouse. E.P. 154,635, 27.2.19.

ELECTROLYTIC deposition of metals in a non-coherent form is effected in an electrolytic cell provided with a rotating drum cathode preferably composed of carbon impregnated with paraffin wax or the like. A cell having a number of cathodes rotating in the direction of flow of the electrolyte may be employed. The carbon anode is of trough form, and a narrow annulus for passage of electrolyte is left between the anode and cathode. The surface of the anode is impregnated with paraffin wax or the like. The active area of cathode surface can be regulated by means of adjustable rubber pads. The depth of electrolyte is regulated by adjustable weirs, and the deposit is removed from the cathode by means of a shoot or scraper, a wiper or the like serving to propel the deposit along the shoot.—J. S. G. T.

Alloy for electrical contact-points. J. A. Williams. U.S.P. 1,358,908, 16.11.20. Appl., 28.10.18.

THE alloy consists of silver with less than 1% of lead.—J. H. L.

Compound metallic articles; Method of making ——. G. A. Mead, Assr. to The Ohio Brass Co. U.S.P. 1,359,719, 23.11.20. Appl., 22.10.19.

AN article of two dissimilar metals is made by coating the fused surface of one of the metals with a dissimilar metal of lower melting point to form a bond, to which the fused second metal is then applied at a temperature higher than the melting point of the coating metal.—J. S. G. T.

Copper; Method of hardening ——. B. Kieffer. U.S.P. 1,359,810, 23.11.20. Appl., 2.2.20.

COPPER is heated to a temperature somewhat below its melting point, finely divided glass is applied to its surface, and it is then cooled rapidly.—J. W. D.

Alloy of alkaline-earth metals; Production of ——. G. J. Kroll. U.S.P. 1,359,813, 23.11.20. Appl., 30.1.20.

A HEATED mixture or alloy of an alkali metal (or magnesium or beryllium) is treated with a molten mixture of chemical compounds containing at least one halogen compound of the alkaline-earth metal to be alloyed.—J. W. D.

Alloy; Hard lead ——. W. A. Cowan, Assr. to United Lead Co. U.S.P. 1,360,269, 30.11.20. Appl., 11.8.19.

A HARD lead alloy contains lead with a small percentage of lithium.—T. H. Bu.

Alloy; Lead-base ——. E. De Campi, Assr. to United Lead Co. U.S.P. 1,360,272, 30.11.20. Appl., 30.7.19.

ALUMINIUM is mixed with a metal or metals capable of alloying with it, and the mixture introduced into alloys composed mainly of lead.—T. H. Bu.

Alloy; Hard lead ——. T. F. Weltstein, Assr. to United Lead Co. U.S.P. 1,360,339, 30.11.20. Appl., 2.10.18. Renewed 28.5.20.

A HARD lead alloy contains at least 97% Pb, the remainder being barium and calcium; the amount of barium is 1¼ to 8 times that of calcium.
—T. H. Bu.

Alloys; Lead-base ——. *Lead alloy.* G. H. Worrall, Assr. to United Lead Co. U.S.P. (A) 1,360,346 and (B) 1,360,347, 30.11.20. Appl., 11.8.19. Renewed 28.5.20.

HARD lead alloys suitable for bearings with lead as the principal constituent contain in addition (A) 3% or less of one of the alkali metals and 2% or less of mercury, or (B) 2% or less of magnesium and 2% or less of mercury. (*Cf.* E.P. 141,122 of 1919; J., 1920, 414 A.)—T. H. Bu.

Hard lead alloy. G. H. Worrall, Assr. to United Lead Co. U.S.P. 1,360,348, 30.11.20. Appl., 25.8.19. Renewed 28.5.20.

LEAD alloys of predetermined hardness are made by hardening a lead-base alloy containing upwards of 90% Pb by adding a small percentage of mercury.
—A. B. S.

Bismuth; Process of extracting ——. J. F. Cullen and M. J. Udy, Assrs. to United States Smelting, Refining, and Mining Co. U.S.P. 1,360,271, 30.11.20. Appl., 19.3.18.

THE ore or other material is leached with brine containing an acid to form a solution of the bismuth salt of the acid, and the bismuth is then precipitated from the solution.—T. H. Bu.

Smelting; Process of ——. J. Lund. U.S.P. 1,360,552, 30.11.20. Appl., 10.12.17.

A "PUFFED" slag, in the pores of which sodium carbonate and petroleum coke have been precipitated, is introduced into a furnace in proximity to the charge, and the material and slag are heated, the latter acting as a flux.—T. H. Bu.

Alloy. F. Milliken, Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S.P. 1,360,773, 30.11.20. Appl., 8.10.19.

THE alloy contains 8—12% Fe, 55—65% Cu, 12—18% Ni, 11—17% Zn, and about ½—1% Si.
—T. H. Bu.

Metallurgical process. G. T. Hansen. U.S.P. 1,361,459, 7.12.20. Appl., 10.1.19.

GOLD, silver, and copper are extracted from ores by leaching the ore with a solution of potassium cyanide at ordinary temperatures, collecting and heating the solution to 90° F. (32° C.) or higher, and subjecting the hot solution to the action of a metal, such as zinc, aluminium, etc.—T. H. Bu.

Electrolytic de-tinning bath for the complete or partial de-tinning of tin-plate. P. Rocksch. G.P. 326,048, 22.1.20.

AN aqueous solution of aluminium chloride is used as the electrolyte. In order to recover the tin from one side only of tinned metal, two sheets are placed together to form the anode in a 3% aluminium chloride solution with a cathode on each side.
—D. F. T.

XI.—ELECTRO-CHEMISTRY.

PATENTS.

Electric furnaces. D. F. Campbell. E.P. 153,951, 14.8.19.

THE furnace electrodes are adapted to be tilted and fed by mechanism supported independently of the furnace body, so that the furnace may be employed either as an arc or resistance type of furnace. The electrodes, when tilted, are brought into contact with carbonaceous material, such as coke, applied to the surface of the charge.—J. S. G. T.

Electric furnace. Process of treating charge materials in electric furnaces. C. E. Parsons. U.S.P. (A) 1,359,735 and (B) 1,359,736, 23.11.20. Appl., 19.2.20.

(A) MEANS are provided for feeding the material to be treated in the furnace in an upward direction between the electrodes, for withdrawing it therefrom in a downward direction, for maintaining the interior of the furnace airtight, and for subjecting the material to suction while being treated. (B) Material to be treated is fed to and withdrawn from the furnace as described under (A). The material is made electrically conducting and then when molten is caused to impinge against a sharp edge to prevent sticking.—J. S. G. T.

Electrical oxidation of gases; Furnaces for ——. B. Thomas. U.S.P. (A) 1,359,932 and (B) 1,359,933, 23.11.20. Appl., 18.7.17.

(A) THE furnace electrodes are formed of closely coiled pipe and are placed one within the coils of the other, so as to form an annular arcing chamber. Means are provided for circulating a cooling fluid through the pipes. (B) Two concentric electrodes are spaced so as to form an annular air inlet passage which is provided with inclined vanes to impart a whirling motion about the axis of the electrodes to the incoming air.
—J. S. G. T.

Electrolysers; Bi-polar electrode ——. G. G. Hepburn, and Mather and Platt, Ltd. E.P. 154,029, 26.9.19.

IN bi-polar electrode electrolysers of the type described in E.P. 12,730 of 1915 (J., 1916, 1120) side and bottom walls or divisions are provided between the electrodes so that the space between the electrodes is open only at the top. Channels for drawing off electrolyte extend from the active face of an electrode and through it to the end face, and an aperture for the same purpose is arranged in the side wall either near the bottom of the cell, or near the top, with an intermediate side wall extending over the aperture nearly to the bottom of the cell.
—J. S. G. T.

Electrolytic cell [; Anode for ——]. E. A. Le Sueur. U.S.P. 1,359,716, 23.11.20. Appl., 13.5.18.

AN anode for an electrolytic cell consists of a carbon plate extending laterally and downwards from a carbon lead, with another carbon plate of smaller width extending laterally from the lead above the first plate and substantially in the same plane.
—J. S. G. T.

Electrolytic cell. G. K. Thomas. U.S.P. 1,360,055, 23.11.20. Appl., 17.5.20.

ONE of the electrodes of the cell is enclosed within an envelope provided with apertures through which alone the electrolyte is able to come into contact with the enclosed electrode.—J. S. G. T.

Electrolytic apparatus. Water-feed attachment for electrolytic cells. Electrolytic cell. Electrode. I. H. Levin. U.S.P. (A) 1,360,541, (B) 1,360,543, (C) 1,360,544, and (D) 1,360,545, 30.11.20. Appl., (A) 25.10.15, (B, C, D) 21.4.19. All renewed 23.4.20.

(A) An electrolytic apparatus of the filter-press type comprises a number of electrodes separated by diaphragms and provided with openings lined with insulating material forming independent feed ducts for electrolyte. (B) A chamber for feed water is provided with passages discharging within the electrolytic cell. Baffles are arranged within the chamber, above and near the ends of the passages, and a perforated shield is placed above the baffles. Gas derived from bubbles bursting in the chamber, passes through the shield, and the liquid envelopes of the bubbles are returned to the chamber. (C) The cell casing is provided with an opening, the walls of which converge towards the inside of the cell, and into which a tapered resilient body of insulating material, provided with an opening through which the electrode terminal passes, can be forced. (D) An electrode comprises two sheet metal plates having oppositely disposed depressions near the top, and separated by a flat metal terminal bar of about the same width as the depressions. The plates and bar are mechanically and electrically connected by a weld joint, whereby electrolyte is excluded from between the plates and the bar.
—J. S. G. T.

Electrolytic apparatus. I. H. Levin, Assr. to Electrolytic Oxy-Hydrogen Laboratories, Inc. U.S.P. 1,360,542, 30.11.20. Appl., 25.5.17. Renewed 23.4.20.

An electrolytic tank is divided into a number of chambers by a partition in electrical connexion with the lower portion of the tank. The partition is provided with an opening. An inner electrode enclosed by a diaphragm is contained within each chamber. The gas-tight cover of the tank carries a number of inverted troughs projecting to a point below the normal level of electrolyte, each inverted trough being associated with an elongated trough the sides of which merge into the sides of the respective inverted troughs. The tops of the elongated troughs are partly open, but are closed where the walls of the troughs merge into one another. Means are provided whereby the electrolyte and water for diluting the electrolyte may flow from respective chambers into an elongated trough on either side of the wall of the inverted trough. A feed cup is provided with ducts leading to one of the chambers formed by the partition and a gas offtake system communicates with all the inverted troughs.
—J. S. G. T.

XII.—FATS; OILS; WAXES.

Soya bean oil; Direct identification of ——. C. A. Newhall. J. Ind. Eng. Chem., 1920, 12, 1174—1175.

Five c.c. of the oil is mixed with a few drops of gum arabic solution and 5 c.c. of 2% uranium acetate or nitrate solution, 5 c.c. of choroform is added, and the mixture is shaken thoroughly. Crude and refined soya bean oils yield a characteristic yellow emulsion, but other oils, with the exception of linseed oil, give a white or very slightly coloured emulsion; linseed oil gives a light brownish colour. The test will detect the presence of 5% of soya bean oil in earthnut (arachis), cottonseed, sesame, rape, and coconut oils.—W. P. S.

Prickly pear seed oil. S. Lomanitz. J. Ind. Eng. Chem., 1920, 12, 1175.

Prickly pear seeds yield about 11% of a semi-drying oil having the following characters:—Sp. gr. at 15·5°/15·5° C., 0·9294; n_D^{40}=1·4676; acid value, 3·09; saponif. value, 189·5; iodine value, 116·3; Reichert-Meissl value, 2·8; insoluble fatty acids, 93·81%.—W. P. S.

Patents.

Fish oils; Deodorisation and other purification of ——. De Nordiske Fabriker De-no-fa Aktieselskap. E.P. 140,372, 13.1.20. Conv., 18.3.19.

Whale or other fish oil, after treatment with a solution of sodium hydroxide or sulphuric acid, is hydrogenated in an autoclave for 4—6 hrs. at 150°—200° C. in the presence of a small quantity of nickel catalyst until the iodine value is reduced from about 125 to about 100. The hydrogenated oil, after filtration, is slightly polymerised by heating to 260°—280° C. for 3—4 hrs. in a closed vessel through which hydrogen is passed, and, after cooling to 80°—100° C., is finally deodorised by treatment *in vacuo* with steam superheated to 250°—300° C.
—L. A. C.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Paints; Detection of oils other than linseed in —— *by means of the hexabromide value of the fatty acids.* H. Bailey and W. D. Baldsiefen. J. Ind. Eng. Chem., 1920, 12, 1189—1194.

The hexabromide value of pure linseed oil is 42, of soya bean oil 6, and of fish oils 0; the latter, however, yield ether-insoluble octobromides which can be separated from the hexabromides of the other oils by taking advantage of their insolubility in warm chloroform. The method adopted for brominating the fatty acids consists, briefly, in dissolving 1 g. of the fatty acids in 25 c.c. of ether and 2 c.c. of glacial acetic acid, cooling the solution to −10° C., and adding about 2·5 c.c. of a mixture of 20 c.c. of bromine and 80 c.c. of glacial acetic acid.—W. P. S.

Varnishes with furfural. C. Coffignier. Bull. Soc. Chim., 1920, 27, 865—867.

Furfural, introduced into varnishes with resinates (*cf.* F.P. 494,300 of 1918), plays exactly the same part as does turpentine. Like this latter solvent it evaporates during the drying of the layer of varnish. Its rôle is thus simply that of a volatile solvent.—W. G.

Patents.

Solvents; Process for the recovery of —— [from surface coatings of dopes, etc.]. E. I. Du Pont de Nemours and Co., Assees. of T. Baker. E.P. 130,962, 5.5.19. Conv., 8.8.18.

The object in process of being coated with a composition containing an alcohol is supported adjacent to a vaporising chamber, and gradually advanced through a restricted, adjustable opening in the latter as successive portions are coated. The vapour-laden air is withdrawn from the chamber through a cooler and thence into an absorbing agent consisting essentially of wood tar oil, from which the alcohol is recovered by distillation.—W. E. F. P.

Oleaginous substances [tung oil]; Process of producing solidification of ——. B. Scobel. E.P. 153,942, 5.8.19.

A solid material suitable for making tiles for flooring or other purposes is prepared by agitating a solution of a hydrated or anhydrous metallic halide, *e.g.*, ferric chloride, in an anhydrous solvent, such as acetone, with tung oil; the mixture is allowed to stand or subjected to vacuum to remove trapped air, and is subsequently heated in moulds to 80°—100° C. to cause solidification. Application of pressure during this stage increases the firmness and density of the product. Fillers such as silica or insoluble silicates, Prussian blue, graphite, iron or chromium oxides, wood or cork flour, rosin, or gums may be added to the oil before treatment.—L. A. C.

White pigment. P. Farup, Assr. to Titan Co. A/S. U.S.P. 1,360,737, 30.11.20. Appl., 10.3.19.

A titanium hydroxide is intimately mixed with a small amount of phosphoric acid, or a titanium oxygen compound containing iron is treated with sulphuric and phosphoric acids, the product heated with sodium chloride, and the resulting mass lixiviated.—C. I.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchoucs [; Artificial ——], particularly two dimethylcaoutchoucs [methyl-rubbers]. H. Pohle. Kolloidchem. Beihefte, 1920, **13**, 1—60. Chem. Zentr., 1920, **91**, IV., 683—684.

An extensive comparison is made of the properties of two dimethylbutadiene rubbers, covering the effect of colloidal coagulation and dispersion, solubility, oxidisability, and absorption of benzene vapour. A coagulation structure has no lasting influence on the properties of the rubber, and the solubility relations, although affected by resins, are unaffected by protein matter. Methyl-rubber containing an added organic solvent in place of resins shows improved elasticity and resistance to atmospheric action, but, on account of the volatile character of the organic liquid, tends to develop porosity on vulcanisation. Three "ideal" conditions are recognisable in rubber, the absorbent-insoluble, absorbent-soluble, and soluble-non-absorbent; good natural rubber exhibits a combination of the first and second, whereas synthetic rubbers generally are distinguished by the additional presence of the third condition. In the presence of the third condition, rubber shows a greatly increased absorbent power for benzene vapour. According to this view the mechanical working of rubber does not effect any true depolymerisation.—D. F. T.

Rubber articles; Microsections cut from vulcanised ——. H. A. Depew and I. R. Ruby. J. Ind. Eng. Chem., 1920, **12**, 1156—1159.

Microscopical examination of sections of coloured rubber articles affords valuable information as to the dispersion of the pigment; the examination also aids in the identification of the compounding ingredients, such as reclaimed rubber, fibre, pigment, etc. The presence of flocculated pigment possibly accounts for the heating up observed in the case of tire treads heavily compounded with carbon black.—W. P. S.

Rubber compounds; Ageing of certain ——. I. R. Ruby and H. A. Depew. J. Ind. Eng. Chem., 1920, **12**, 1155—1156.

Various fast-curing motor tyre tread compounds were subjected to an accelerated ageing test in an air-bath at 70° C. The results showed that a compound containing lithopone aged somewhat less satisfactorily than one containing zinc oxide; a compound containing carbon black was much inferior to the others as regards tensile strength and elongation after ageing.—W. P. S.

Antimony in rubber goods; Determination of ——. S. Collier, M. Levin, and J. A. Scherrer. India-rubber J., 1920, **60**, 1297—1298.

The sample (0·5 g.) is extracted with acetone and, if mineral oil or "substitute" is present, further with chloroform until the extract is no longer coloured; after drying in a vacuum, the material is heated with cymene (25 c.c.) at 130°—140° C. in a 300 c.c. flask until the rubber has completely dissolved; the cooled liquid is diluted with 250 c.c. of light petroleum spirit (max. b. p. 45° C.) and the mixture left overnight, being then decanted through a Gooch crucible; after washing ten times with petroleum spirit the residue is dried and shaken with hydrochloric acid (30 c.c.) until the antimony sulphide has passed into solution; the solution is filtered slowly through the dried Gooch crucible and, after dilution, the antimony is precipitated with hydrogen sulphide; the antimony is then estimated, *e.g.*, by heating with sulphuric acid (12—15 c.c.) and potassium sulphate (5 g.) in a Kjeldahl flask until a colourless solution is obtained, diluting to about 100 c.c. with water, adding hydrochloric acid (20 c.c.) and sodium sulphite (1—2 g.), boiling to expel all sulphur dioxide, and titrating with $N/10$ permanganate.—D. F. T.

Patents.

Rubber substitute and process for producing same. H. H. Haseltine and M. Gregory, Assrs. to Western Rubber Co. U.S.P. 1,360,744, 30.11.20. Appl., 16.3.18. (*Cf.* E.P. 123,114 of 1917; J., 1919, 227 A.)

A mixture of fixed oils and sulphur, free from air and moisture, is heated under pressure for a sufficient period to complete the reaction.— D. F. T.

Rubber; Treatment of raw ——. J. V. Worthington and A. W. T. Hyde, Assrs. to Dunlop Rubber Co., Ltd. U.S.P. 1,360,486, 30.11.20. Appl., 17.5.20.

See E.P. 150,043 of 1919; J., 1920, 698 A.

XV.—LEATHER; BONE; HORN; GLUE.

Hide-tannin compound; Nature of the —— and its bearing on tannin analysis. J. A. Wilson and E. J. Kern. J. Ind. Eng. Chem., 1920, **12**, 1149—1152.

Tannin once combined with hide substance cannot be removed to an appreciable extent by any amount of washing that would be practicable. Chemical changes are produced in a tan liquor when this is boiled or evaporated, certain non-tannins being converted into substances capable of tanning; such changes can be followed quantitatively by a method described recently by the authors (J., 1920, 522 A), and this method can also be used to study the ageing of leather.—W. P. S.

Chrome tanning; One-bath —— and determination of the tanning strength by means of the agglutination method. E. Stiasny. Collegium, 1920, 479—485.

A CRITICISM of Griliches' work (J., 1920, 633 A). Chromium salts do not split up into a basic portion and a chromosulphuric acid (*cf.* Z. physik. Chem., 1904, 47, 29), but into a basic chromium salt and free sulphuric acid, both of which are present in a chrome tanning liquor. In the early stages of the chrome tanning process there is a preponderant absorption of acid, and in the later stages of the tannage an increasing and finally a preponderant absorption of the basic portion. Objection is taken to Griliches' use of pickled pelt in his experiments. Basicity should be expressed in terms of metal ions and acid ions. Kobert (J., 1917, 297) proposed to determine tannin strength by the coagulating power of different solutions on red blood corpuscles, but the numbers he gave as representing the power of various tannin solutions to coagulate completely red blood corpuscles in no way correspond with the actual values of the tannins in practice, and hence Kobert's deduction that green and violet chromium salt solutions are equally effective is not conclusive. —D. W.

Sulphuric acid in leather; Behaviour and determination of free ——. W. Moeller. Collegium, 1920, 465—470.

A REPLY to Immerheiser (J., 1920, 731 A), in which it is maintained that the ether extraction method of that author (J., 1919, 227 A) is entirely unsuited to the estimation of free sulphuric acid in leather. —D. W.

Leather; Determination of hydrochloric acid and neutral chlorides in ——. A. W. Thomas and A. Frieden. J. Ind. Eng. Chem., 1920, 12, 1186—1188.

ONE g. of leather is mixed with 200 c.c. of $M/10$ NaH_2PO_4 solution and heated at 100° C. for 2 hrs.; after cooling, the solution is diluted to 250 c.c., filtered, 200 c.c. of the filtrate is acidified with nitric acid, heated, silver nitrate solution and a further quantity of 20 c.c. of concentrated nitric acid are added, the mixture evaporated in the dark to about 50 c.c. (to oxidise and dissolve precipitated organic matter), diluted to 200 c.c., and the silver chloride collected and weighed. The total amount of chloride in the leather is calculated from the weight obtained. A second portion of 1 g. of the sample is then digested with 200 c.c. of 95% alcohol at 75° C. for 2 hrs., cooled, diluted with alcohol to 250 c.c., and the mixture filtered; 200 c.c. of the filtrate is rendered alkaline with sodium hydroxide, evaporated to remove alcohol, the residual solution treated with nitric acid and silver nitrate, and the silver chloride collected as described above, and weighed. This weight is a measure of the neutral chlorides present, the difference between the two determinations giving the quantity of acid chlorides.—W. P. S.

Casein; Technical ——. I. W. M. Clark. J. Ind. Eng. Chem., 1920, 12, 1162—1163.

A DESCRIPTION of the measures adopted by the U.S. Government to ensure a supply of casein for the manufacture of waterproof glue used in aeroplanes. A part of the work done by the Dairy Division of the Department of Agriculture is reported in the following abstracts.—W. P. S.

Casein; Technical ——. II. Grain-curd casein. W. M. Clark, H. F. Zoller, A. O. Dahlberg, and A. C. Weimar. J. Ind. Eng. Chem., 1920, 12, 1163—1167.

A HIGH-GRADE casein may be obtained by heating skimmed milk as free as possible from fat to 93° F. (34° C.) and adding dilute hydrochloric acid (1:8 by wt.) until coagulation just commences; after the curd has settled, about one-half of the whey is drawn off, the curd is broken up thoroughly, and more of the acid is added until a portion of the whey when tested with methyl-red solution indicates an apparent acidity of $p_H=4.8$ to 4.6. The remainder of the whey is then drawn off, the casein washed with water containing a small quantity of hydrochloric acid ($p_H=4.8$), collected on a draining cloth, washed further, pressed, ground, and dried at 125° F. (52° C.).—W. P. S.

Casein; Technical ——. III. Methods of analysis. R. H. Shaw. J. Ind. Eng. Chem., 1920, 12, 1168—1170.

MOISTURE is determined by drying at 100° C. under reduced pressure, and ash by treating 3 g. of the casein with 5 c.c. of calcium acetate solution, drying the mixture and igniting it at a low red heat; the amount of CaO resulting from the added calcium acetate is deducted from the weight obtained. Sugar is determined by shaking 10 g. of the casein for 4 hrs. with 250 c.c. of 50% alcohol, allowing the mixture to settle, and using 100 c.c. of the clear solution for the determination. Phosphorus is determined by the official (American) method for the determination of phosphorus in fertilisers, whilst calcium may be determined either in the ash or after the casein has been digested with *aqua regia*.—W. P. S.

Casein; Technical ——. IV. Standardisation of the borax solubility test for commercial caseins. H. F. Zoller. J. Ind. Eng. Chem., 1920, 12, 1171—1173.

THE viscosity of casein in borax solution is at a maximum at a hydrogen ion concentration of $p_H=8.15$, whilst at $p_H=8.99$ to 9.1 the viscosity is lower, but constant owing to the buffer effect of borax in this region. The concentration of casein chosen for the improved casein-borax test is about 12% of true casein in $M/5$ sodium borate solution. The differences in the physical structure of caseins have a greater influence on their viscosity than have the normal contaminating substances present in commercial caseins; high-temperature caseins always exhibit a comparatively great initial viscosity.—W. P. S.

PATENTS.

Skins; Method of puering or bating ——. J. T. Wood. E.P. 154,103, 4.2.20.

THE skins are puered or bated on the grain side only by painting that side with an enzyme paste. —L. A. C.

Organic matter, more particularly animal bodies; Apparatus for boiling and drying —— [for recovering glue and fat]. K. Niessen. E.P. 137,843, 13.1.20. Conv., 2.1.17. (*Cf.* G.P. 317,818, 318,542, and 319,335-6; J., 1920, 379 A, 498 A.)

IN an apparatus for the recovery of glue and fat from animal bodies an elbow pipe is fitted through the wall of the boiling tank at about the surface of the liquid; this pipe may be rotated by means of an external handle so that the fat and glue water, or fat alone, may be discharged from the chamber. —W. P. S.

Casein compounds; Process of producing hardened ——. H. P. Bassett. U.S.P. 1,360,356, 30.11.20. Appl., 25.2.20.

CASEIN is precipitated in the presence of a hardening agent, dried until it contains 18—20% of moisture, and then moulded under the action of heat and pressure.—A. B. S.

XVI.—SOILS; FERTILISERS.

Soil reaction; Absorption of phosphoric acid and ——. M. Wrangell. Landwk. Vers.-Stat., 1920, **96**, 209—262.

SEVERAL series of experiments were carried out on the absorption of phosphate by maize and mustard plants in soils to which the other necessary manurial constituents were added, and in which the reaction was kept either neutral, alkaline, or acid with citric acid or sulphuric acid. The effect of the addition of calcium carbonate to these soils was also observed. The crops were gathered and analysed. The results showed that maize could utilise difficultly soluble phosphates in an acid soil only, and the addition of lime reduced the amount of phosphate absorbed. Mustard, on the other hand, was able to absorb the same phosphates in more alkaline solution. The absorption of lime and phosphate by maize was in the ratio of 3:1, and by mustard 15:1. This ratio affords an indication of the capability of the plant to utilise phosphate and to produce a change of reaction in neutral soils. The solution of the plant nutrients in the soil appeared to depend on the differential absorption of the cations and anions, and on the change in reaction induced thereby. The cations were preferentially absorbed in the early stages of growth, thus rendering the reaction of the soil favourable for the subsequent absorption of phosphate. These processes were accelerated by the addition of basic and acid solutions. The reaction of the soil was most easily regulated by the use of nitrogenous manures, especially ammonium salts and nitrates. Free citric acid was decomposed in a few days, and the carbon dioxide formed appeared to have a considerable influence on other decomposition processes in the soil. —J. H. J.

Moisture in field samples of soil; Determination of ——. H. A. Noyes and J. F. Trost. J. Assoc. Off. Agric. Chem., 1920, 4, 95—97.

IN determining moisture in field samples of soil less than 10 g. should never be taken if accurate results are to be obtained.—W. G.

Soil phosphorus; Technique of determination of ——. H. A. Noyes. J. Assoc. Off. Agric. Chem., 1920, 4, 93—94.

THE prepared air-dry soil (10 g.) is digested by the usual Kjeldahl method for total nitrogen, using 0·7 g. of mercuric oxide, and adding 0·5 g. of sodium or potassium nitrate to complete the oxidation. When the liquid is partially cooled, 200 c.c. of water is added, the mixture made up to 250 c.c., filtered, and 25 c.c. of the filtrate is boiled with 15 g. of ammonium nitrate and then treated with 30 c.c. of ammonium molybdate solution, and the phosphorus determined as usual.—W. G.

Moisture determination [in fertilisers]; New method for ——. G. F. Lipscomb and W. D. Hutchins. J. Assoc. Off. Agric. Chem., 1920, 4, 55—57.

ONE gram of the material is weighed into a small cup which is then lowered into a thick-walled tube having its lower end heated in a steam-jacket. This tube is fitted with a hollow ground-in stopper and has a side tube connected with a pump by means of which the tube is evacuated. The hollow stopper is filled with a mixture of solid carbon dioxide and ether. After being in the apparatus for 5 mins., the cup is removed, cooled in a desiccator, and weighed. This process is repeated until a constant weight is obtained, and as a rule five heatings of 5 mins. suffice. Owing to the short period of heating and the material being in a vacuum there is little risk of decomposition in materials such as cottonseed meal, fish scrap, or other organic substances.—W. G.

Moisture determinations in fertiliser materials; Double ——. J. O. Clarke. J. Assoc. Off. Agric. Chem., 1920, 4, 57—59.

EMPHASIS is laid on the necessity for double moisture determinations, *i.e.*, both before and after preparing the sample for analysis by grinding, so that percentages may be calculated back to the original sample. These double determinations are particularly necessary in fertilisers where the moisture is above 10% and the percentage of the active constituent is fairly high.—W. G.

Phosphoric acid in precipitated phosphate; Effect of mass and degree of fineness on the percentage of available ——. H. D. Haskins. J. Assoc. Off. Agric. Chem., 1920, 4, 64—66.

THE precipitated phosphate examined was prepared by neutralising with slaked lime the phosphoric acid obtained in the manufacture of glue. The available phosphoric acid was estimated with ammonium citrate solution neutral to cochineal and to litmus respectively, and a somewhat higher result was as a rule obtained with the second solution where 2 g. samples were used. The availability was appreciably higher when the material was ground to pass a 100-mesh sieve than when ground to pass only a 1-mesh sieve. Further grinding did not increase the availability to any great extent. With materials containing such a high percentage (nearly 40%) of available phosphoric acid it would appear desirable to use only 1 g. of the material instead of 2 g. for the estimation.—W. G.

Ammoniacal nitrogen in complex manures containing calcium cyanamide and ammonium salts; Determination of ——. J. Froidevaux and H. Vandenberghe. Chim. et Ind., 1920, 4, 612—616.

AMMONIACAL nitrogen cannot be estimated in the presence of calcium cyanamide by distillation with magnesia, as, under such conditions, the cyanamide loses some of its nitrogen as ammonia. The best method is to bubble air through an ice-cold solution of the mixture to which an excess of 40% sodium hydroxide solution has been added, collecting the ammonia in standard acid. If the ammonia evolved is estimated at hourly intervals the curve plotted consists of two straight lines, almost at right angles, joined by a slight curve at a point corresponding to about five hours' distillation. If the two straight lines are continued the point at which they intersect will correspond, within the limits of error, to the nitrogen present in the original mixture as ammonium salts, the second portion of the curve representing the loss of nitrogen from the cyanamide.—W. G.

Potash in wood ashes etc. Haskins. *See* VII.

PATENTS.

Fertilisers and method of manufacture. W. H. Hyatt and E. N. Fellowes. E.P. 153,434, 26.9.19.

NITRE-CAKE in as dry a state as possible is mixed with rather more chalk than is necessary to neutralise the acidity of the cake, and the mixture is ground to a fine powder. The product contains calcium carbonate about 13%, calcium sulphate 7·6%, sodium sulphate 47·6%.—J. H. J.

Fertiliser and insecticide. W. B. Baker and M. C. Shepherd. E.P. 154,057, 31.10.19.

NORTH SOMERSETSHIRE granite dust is intimately mixed with freshly slaked lime and charcoal or soot, suitable proportions being 56, 35, and 21 lb. respectively, and the mixture is allowed to stand for a few days before use. The product has both fertilising and insecticidal properties. Analysis of a sample gave: moisture, 1%; phosphoric acid, 0·96%; nitrogen, 1·4%; and potassium, 0·22%. —W. J. W.

Sulphur composition. Phosphate composition. J. G. Lipman. U.S.P. (A) 1,361,596 and (B) 1,361,597, 7.12.20. Appl., 10.4. and 26.8.20.

(A) A DRY composition containing sulphur and latent sulphofying bacteria. (B) A dry composition containing dry pulverised phosphatic material and a dry culture of sulphofying bacteria.—A. B. S.

Phosphate. U.S.P. 1,360,248. *See* VII.

XVII.—SUGARS; STARCHES; GUMS.

[Sugar] juice; Entrainment and decomposition of —— during boiling in evaporators as an explanation of unknown losses. A. Schweizer. Arch. Suikerind. Nederl.-Indië, 1919, 27, 2010—2013. Int. Sugar J., 1920, 22, 706—707.

A CONSIDERABLE loss of sucrose has been observed during the evaporation of juice in certain factories in Java, and was considered not to be due to entrainment, since negative results were obtained on examining the condenser water by means of α-naphthol. It is suggested that during evaporation the juice carried forward in the form of spray is "atomised" as the result of the high velocity of the steam, and that in this state decomposition occurs, not only to the stage of invert sugar (*cf.* Abelous and Aloy, J., 1919, 475 A), but even to the production of carbon dioxide and water.—J. P. O.

[Sugar] juice; Entrainment and decomposition of —— during boiling in evaporators as an explanation of unknown losses. F. G. E. Olsen. Arch. Suikerind. Nederl.-Indië, 1920, 27, 2161. Int. Sugar J., 1920, 22, 707—708.

IN order to examine Schweizer's theory (*cf. supra*), steam was drawn off at two points in the multiple effect evaporator, *viz.*, just before the juice-separator, and beween the juice-separator and the condenser. Examination of the water obtained on condensing the withdrawn steam showed the presence of much sucrose at the first point with a little invert sugar, but less sucrose and more invert sugar at the second, while the condenser water appeared to be free from sucrose. It is, therefore, concluded that in the vapour lines of the evaporator there was a certain amount of entrainment of sucrose in the form of juice spray, and that this sucrose was first inverted and later totally destroyed.—J. P. O.

[Sugar] juice; Entrainment and decomposition of —— during boiling in evaporators as an explanation of unknown losses. J. S. de Haan. Arch. Suikerind. Nederl.-Indië, 1920, 28, 223—271.

Loss of sucrose may occur due to the passing of juice spray from the evaporators into the condenser waters, and yet the latter may indicate negative results on being tested according to the general procedure with α-naphthol (*cf. supra*), owing to the fact (proved by means of a laboratory apparatus) that the two liquids do not mix together under the conditions prevailing in practice. In the case of molasses spray at 85° Brix the drops reached the bottom of the column of the Torricellian condenser almost unchanged. By installing an efficient form of spray-catcher (which separated the particles of juice by centrifugal force), it was possible in one of the factories to reduce the loss during evaporation from 3·12 to 0·78% of the sucrose in the cane while in two others the improvement was almost equally satisfactory.—J. P. O.

Glucose [dextrose] and starch; Determination of —— by the alkaline potassium permanganate method. F. A. Quisumbing. Phillipine J. Sci., 1920, 16, 581—601.

25 c.c. of the sugar solution (*e.g.*, hydrolysed starch solution) is boiled with 50 c.c. of $N/10$-potassium permanganate solution and 25 c.c. of 0·4 N sodium carbonate, under strictly standardised conditions. The excess of permanganate is determined by means of standard oxalic acid solution, and the quantity of dextrose found by reference to a table. Applied to commercial starch, after hydrolysis by acid or diastase, the method gave results agreeing with those of Munson and Walker's method (J., 1906, 656). Satisfactory agreement was obtained also in the determination of starch in flours, after hydrolysis by saliva or diastase, but after hydrolysis by acid the method gave results about 10% higher than those obtained by Munson and Walker's method. —J. H. L.

Starchy materials; Contrary action of soluble chlorides and sulphates on ——. H. Courtonne. Comptes rend., 1921, 171, 1168—1170.

IN the presence of solutions of certain chlorides, at the ordinary temperature, starch is slowly converted into starch paste, and this in turn is converted into soluble starch if the mixture is heated to 115° C. The ease with which these changes take place depends on the solubility of the chloride and the concentration of the solution. A saturated solution of magnesium chloride is the most effective. Cold solutions of potassium, sodium, and ammonium chlorides have no such effect, while with hot solutions the action is very slight. Sulphates, on the other hand, retard these changes. In a saturated solution of magnesium sulphate starch grains show no signs of swelling even when heated to 115° C. in a closed vessel and there is no formation of starch paste.—W. G.

PATENTS.

Adhesives [gum substitutes]; Manufacture of —— [and of glycerin substitute]. H. Wallasch. G.P. 325,647, 22.5.19. Addn. to 323,665 (J., 1920, 759 A).

THE formaldehyde and dicyanodiamide can be made to react in the absence of any condensation agent or with other acidic or dehydrating substances than sulphuric acid; the product at a stage before it becomes adhesive is of value as a substitute for glycerin.—D. F. T.

Decolorising carbons. U.S.P. 1,359,094. *See* IIB.

Fermentable sugars. U.S.P. 1,358,898. *See* XVIII.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes. IV. Emulsin, cytase, ereptase, and urease in germinated barley. D. Maestrini. Atti R. Accad. Lincei, 1920, [v.], 29, ii., 164—166. (*Cf.* J., 1920, 244 A, 309 A.)

WHEN treated with 0·3% acetic acid solution, germinated barley yields an extract capable of hydrolysing amygdalin, the emulsin being present in the suspension of the meal as well as in the filtered extract. No cytase, ereptase, or urease could be detected in germinated barley.—T. H. P.

Enzymes; Quantitative action of ——. G. Tammann and O. Svanberg. Z. physiol. Chem., 1920, 111, 49—67.

THE ideal action of an enzyme, which the action of emulsin on salicin resembles, is discussed mathematically.—S. S. Z.

Maltase; Determination of —— in yeast. II. R. Willstätter and W. Steibelt. Z. physiol. Chem., 1920, 111, 157—170.

THE fresh yeast is triturated with ethyl acetate until it liquefies. Water is then added and the mix-

ture is neutralised with ammonia. The yeast suspension is made up to a definite volume with a known maltose solution and a buffer mixture; aliquot portions are withdrawn at two different intervals, the degree of hydrolysis estimated, and the "time value" calculated. The few experiments carried out by this method show that most of the maltase of the yeast is extracted in this way. The method is also suitable for the comparison of the hydrolysis of sucrose and maltose by certain yeasts. —S. S. Z.

Saccharase [invertase]; Susceptibility of —— to heat. H. von Euler and I. Laurin. Z. physiol. Chem., 1919, **108**, 64—115.

A COMPILATION of data in connexion with the inactivation of invertase by heat under various conditions.—S. S. Z.

Fermentation by a top yeast; Susceptibility of —— to the hydrogen ion concentration. H. von Euler and S. Heintze. Z. physiol. Chem., 1919, **108**, 165—186.

EXPERIMENTS with a strain of a top yeast (S B II.), from the Stockholm Södra Iästfabrik, showed that the influence of acidity on the rate of fermentation was dependent on the nitrogen content of the medium, and that the optimum hydrogen ion concentration was about $p_H=5$. In the case of weakly dissociated organic acids, the quantity of the undissociated acid was great in relation to the concentration of the ions and it also influenced the course of fermentation.—S. S. Z.

Alcoholic fermentation. VIII. Influence of zinc chloride on the alcoholic fermentation of living and killed yeast. S. Kostytschew and L. Frey. Z. physiol. Chem., 1920, **111**, 126—131.

ZINC chloride causes the formation of acetaldehyde in fermentation by hefanol and dried yeast but not by living yeast. Apart from the aldehyde the sugar is mainly converted into an unknown compound in the presence of zinc chloride. This production of acetaldehyde only occurs when sugar is present. In the case of autofermentation at room temperature only traces of acetaldehyde can be detected. —S. S. Z.

Alcoholic fermentation. IX. Influence of cadmium and zinc salts on yeast enzymes. S. Kostytschew and S. Subkowa. Z. physiol. Chem., 1920, **111**, 132—140.

CADMIUM salts alter to a very marked extent the normal course of fermentation. Most of the sugar is converted into products of unknown composition, and acetaldehyde is produced at the same time. Proteolysis and, to a greater extent, reduction are inhibited by dilute solutions of cadmium salts, and the reduction of acetaldehyde to alcohol is entirely stopped by small quantities of these salts. Acetaldehyde is produced not only in the presence of oxygen but also under anaërobic conditions. Cadmium salts do not cause the oxidation of ethyl alcohol to acetaldehyde. The action of cadmium and zinc salts is ionic.—S. S. Z.

Alcoholic fermentation. X. Fermentation is life without oxygen. S. Kostytschew and P. Eliasberg. Z. physiol. Chem., 1920, **111**, 141—156.

SEVERAL species of mucor were employed for fermenting sugar under aërobic conditions, and the carbon dioxide produced through direct respiration was estimated. It was found that under the experimental conditions the organisms oxidised the sugar to an extent sufficient to cover their vital energy.—S. S. Z.

Nitrates; Utilisation of —— by moulds for the production of nitrogenous compounds. S. Kostytschew and E. Tswetkowa. Z. physiol. Chem., 1920, **111**, 171—200.

Aspergillus niger and *Mucor racemosus* reduce nitrates and nitrites to ammonia, from which they synthesise amino-compounds with the help of sugar. Nitrous acid, ammonia, and amino-compounds have been definitely observed in the intermediate stages. The nitrite-nitrogen is converted into ammonia and amino-nitrogen outside the hyphæ, but is not assimilated by them as such in experiments of short duration. The reduction of nitrate to nitrite takes place, at least in *Mucor racemosus*, only in the presence of sugar.—S. S. Z.

Sugar; Formation of —— by moulds from non-sugars. S. Kostytschew. Z. physiol. Chem., 1920, **111**, 236—245.

SUGAR and alcohol were formed by *Aspergillus niger* from the following substances: *d*-tartaric acid, glycerol, quinic acid, mannitol, and lactic acid. From peptone, on the other hand, no sugar was formed.—S. S. Z.

Acetaldehyde; Formation of —— in the decomposition of sugar by moulds. C. Cohen. Biochem. Zeits., 1920, **112**, 139—143.

THE formation of acetaldehyde as an intermediate product was established by means of the secondary sulphite "fixation" method in the fermentation of dextrose by *Aspergillus cellulosæ*, *Monilia candida*, *Mucor racemosus*, *Mucor Rouxii*, and *Oidium lactis*. —S. S. Z.

Acetaldehyde as an intermediate product in the fermentation of sugar by Lactis aerogenes. C. Neuberg, F. F. Nord, and E. Wolff. Biochem. Zeits., 1920, **112**, 144—150.

ACETALDEHYDE has been found by the "fixation" method to be an intermediate product in the fermentation of sugar by *B. lactis aerogenes*.—S. S. Z.

Sugar-cane fibre and cottonseed hulls; Acid hydrolysis of —— [for production of alcohol]. E. C. Sherrard and G. W. Blanco. J. Ind. Eng. Chem., 1920, **12**, 1160—1162.

BAGASSE and cottonseed hulls, without previous treatment, are unsuitable for the preparation of ethyl alcohol by direct hydrolysis with acid and subsequent fermentation. Of the total sugars produced by the acid hydrolysis of these materials, only a small quantity is fermentable and the larger proportion consists of pentoses. Bagasse may prove of value as a source of xylose and furfural; in the experiments described, 12·1% of pure xylose, calculated on the quantity of dry sugar-cane fibre, was obtained.—W. P. S.

Alcoholic strength; Tables giving —— from the specific gravity. II. 25—50% of alcohol by weight. G. Tommasi. Ann. R. Staz. Chim.-Agrar. Sperim., 1917—1919, II., **9**, 37—74.

TABLES are given showing percentage of alcohol by weight; percentage of alcohol by volume at 15° C.; and number of grams of alcohol in 100 c.c. at 15° C. for the specific gravities of aqueous alcoholic solutions determined at a number of different temperatures ranging from 10°/15° to 25°/15° C. —T. H. P.

Vinegar; Orange ——. Its manufacture and composition. H. D. Poore. J. Ind. Eng. Chem., 1920, **12**, 1176—1179.

BRIEF descriptions are given of two processes used to produce orange vinegar, one in a small way by the barrel or roller process and the other on a large scale by the well-known generator process. The

vinegar obtained by the latter process contains acetic acid, 3·7—4·1; fixed acid (as citric acid), 1·0—1·2; total solids, 3·82—5·26; ash, 0·52—0·79; P_2O_5, 0·035—0·053; proteins, 0·56—0·75 g. per 100 c.c. The product obtained by the barrel process is slightly higher in acidity.—W. P. S.

Glycerol; Manufacture of —— from sugar. Verein. Chem. Werke A.-G. E.P. 138,328, 21.1.20. Conv., 22.4.16. Addn. to 138,099 (J., 1920, 608 a).

In the process of the chief patent a sulphite is employed as alkaline substance; *e.g.*, 1 kg. of sugar fermented at 30° C. by 100 g. of yeast in 6·6 l. of water containing 100 g. of anhydrous sodium sulphite, yields 14·3% of glycerol and 39% of alcohol; by increasing the amount of sulphite added to 120 g. and 250 g. the yield of glycerol is raised to 16% and 23·5% and that of alcohol lowered to 30% and 24% respectively. Yeast foods and catalysts such as manganese or iron sulphate may be employed, and a further improvement is effected by using in addition to sulphites a small proportion (*e.g.*, 0·2—1% of the sugar) of salts of strongly reducing sulphur acids, such as hydrosulphites or sulphoxylates. The yield of glycerol may thus under certain conditions be raised to 30% of the sugar consumed.—J. H. L.

Yeast; Manufacture of ——. Aktieselskabet Dansk Gaerings Industri, and S. Sak. E.P. 153,667, 11.8.19.

In the manufacture of yeast, especially by the aeration method, mash or wort of higher concentration than that in which the yeast was pitched is added in the course of propagation; the conditions of yeast growth are thus rendered more uniform throughout than when the concentration of the nutritive matters diminishes continuously. For example, the yeast may be pitched in wort (later mash drainings) of 2% Balling, and after 2—3 hrs. the main wort, of 10% Balling, may be added, continuously or intermittently, over a period of 10—11 hrs. By suitable aeration the yeast may be made to assimilate the alcohol formed, to any required extent, or the alcohol may be recovered.—J. H. L.

Sugars; Process of producing fermentable —— [from cellulosic material]. G. H. Tomlinson. U.S.P. 1,358,898, 16.11.20. Appl., 13.6.17.

The material is heated in contact with a hydrolysing agent in a closed vessel, and after saccharification has been effected the pressure is rapidly reduced to below 1 atm. and volatile reaction products are removed by distillation.—J. H. L.

XIXa.—FOODS.

Meat and fish; Absorption of salt by —— from a freezing mixture. S. Schmidt-Nielsen. Tekn. Ukeblad, 1920, **67**, 456. Chem.-Zeit., 1920, **45**, Rep., 313.

When meat and fish are immersed in sodium chloride solution at ordinary temperature they absorb considerable quantities of the salt, but when they are placed in a mixture of ice and salt at −5° to −15° C., or the liquid mixture of the same at this temperature, the absorption of salt is very small and is negligible at a depth of 2 mm. below the surface of the meat. The penetration of the salt is the greater the higher the temperature of the liquid above its freezing point.—W. P. S.

Linseed cake and oil-free mustard residues; Composition and digestibility of ——. F. Honcamp, H. Zimmermann, and O. Nolte. Landw. Vers.-Stat., 1920, **96**, 339—352.

Feeding experiments were made on sheep with a daily ration of 600 g. of hay and 200 g. of linseed cake or 240 g. of oil-free mustard residues. The percentages of the various constituents of the two feeding stuffs digested were: organic matter, 80, 77·6%; crude protein, 83, 86·5%; nitrogen-free extract, 90, 73·6%; ether extract, 96, 88·8%; crude fibre, 35, 52·7%. These results showed that the amount of digestible protein contained in the two feeding stuffs was 27·15% in the linseed and 34·62% in the mustard. The two feeding stuffs are therefore similar in composition and digestibility.—J. H. J.

Crude fibre [in feeding stuffs]; Determination of ——. O. Nolte. Landw. Vers.-Stat., 1920, **96**, 326—337.

Several points affecting the determination of crude fibre in feeding stuffs by various methods were investigated. If the basin used was smaller than the usual 200 c.c. size, low results were obtained, and occasionally also if it was larger. Very rapid boiling also led to low results. If the strength of either the acid or the alkali was diminished below the usual 1·25%, a higher yield of crude fibre was obtained, although the percentages of carbon and hydrogen in it remained the same. The use of a stronger alkali for a shorter time caused the results to be distinctly lower. Whether fat was removed or not before determining the fibre made little difference. A large number of results are given showing the percentages of the particles of various sizes in coarsely and finely ground meals. The amount of crude fibre found in these samples tended to decrease with fine grinding.—J. H. J.

Straw fodder; Determination of the degree of hydrolysis of ——. Von Wissell. Landw. Vers.-Stat., 1920, **96**, 263—275.

The best means of determining the digestibility of fodder prepared by digesting straw of cereals and other material rich in cellulose, with dilute alkali, is to determine the loss in weight on hydrolysis with 1% caustic soda, to apply the phloroglucinol test for lignin, and to determine the chlorine absorbed from bleaching powder.—J. H. J.

Mustard; Determination of crude fibre in prepared ——. M. C. Albrech. J. Ind. Eng. Chem., 1920, **12**, 1175—1176.

High results are obtained in the determination of crude fibre in prepared mustard unless the sample is treated previously for the removal of oil.—W. P. S.

Chymosin and pepsin; Action of ——. VI. Experiments on the preparation of pure stomach enzymes and observations on their action. O. Hammarsten. Z. physiol. Chem., 1919, **108**, 243—286.

On extracting the mucous membrane of the dog, pig, cow, or horse with 0·2% hydrochloric acid and mixing the clear filtered infusion with an equal volume of a saturated solution of sodium chloride, a flocculent hyaline substance is obtained. This substance contains the greater part of the enzymes of the extract. Dilutions of 1:10,000,000 were still active. It could be re-dissolved in dilute acid and reprecipitated with sodium chloride. After five precipitations the fraction still showed strong activity. If the extraction is carried out at body temperature, a precipitate is formed only some time after the addition of the sodium chloride. It is considered that the substance is denatured when extracted at 37°—38° C.—S. S. Z.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Sterilisation of —— *by chlorine gas.* J. S. Arthur. J. Inst. Mech. Eng., 1920, 1127—1198.

A DETAILED account is given of the types of apparatus used for sterilising water for the Army during the war. For a filtered water less than 0·5 pt. of chlorine per million pts. of water is required for complete sterilisation, and for a neutral raw water, such as that of a large river, 3—4 pts. per million with a period of 20 mins. contact. An apparatus devised by Wallace and Tiernan (E.P. 113,105—6, 113,197—8, 113,288, and 113,374; J., 1918, 191 A, 192 A) was adopted as the standard type for the British Army. The apparatus is in two forms. The direct feed chlorinator consists of a pressure compensator, a flow measurer, and a back-pressure valve and diffuser. It delivers a steady flow of chlorine gas at a constant pressure from bottles of liquid chlorine. The accuracy is almost 100%. The solution feed chlorinator is a similar apparatus with a bubble meter in addition, in which the bubbles of gas can be seen and counted as they dissolve in the water in the meter. This water, when saturated, is injected into the bulk of water to be treated. Drawings and plans are given of the portable and stationary plants used in the Army, the process of purification adopted in each being essentially the same and consisting of five steps: Coagulation of suspended matter with aluminium sulphate and alkali; sedimentation; filtration of the supernatant water; sterilisation; de-chlorination with sulphur dioxide. A sand filter is used, and filtration takes place from the top downwards, the sand being kept covered with water; it is flushed by upward flow when it becomes clogged. The amount of chlorine to be added is determined by a preliminary test with a standard solution of bleaching powder. After the addition of chlorine the water is passed through a series of tanks for a period of 20 mins. to complete the sterilisation. For de-chlorination sulphur dioxide gas is used, delivered from a bottle of the liquid through a fine adjustment valve. The amount to be used is determined from time to time by adding potassium iodide and starch to samples of the water after treatment with sulphur dioxide; the development of a blue colour indicates excess of chlorine, and enough sulphur dioxide is added to reduce this colour to less than that produced by 0·5 pt. of chlorine per 100,000 parts of water. This small amount is left in to maintain sterility until the water is consumed, by which time it has almost disappeared and no taste is left.—J. H. J.

Water analysis [; Determination of sulphuric acid in ——]. L. W. Winkler. Z. angew. Chem., 1920, 33, 311—312.

SULPHURIC acid in potable waters may be approximately estimated by observing the time at which the liquid first becomes cloudy, when to 5 c.c. of the clear sample, acidified with 2·5 c.c. of 10% hydrochloric acid, 2·5 c.c. of 10% barium chloride solution is added. The test is conveniently carried out beside a blank experiment in two test glasses standing on a black surface to facilitate observation, and the values for sulphuric acid corresponding with the time are obtained either from a table quoted in the paper, or preferably by actual tests on dilute sulphuric acid solutions of known strength from which a curve showing times and mg. H_2SO_4 can be constructed. For a gravimetric estimation it is generally necessary to concentrate by evaporation unless large quantities of sulphate are present, but incorrect results are obtained unless calcium is first removed by precipitation with 0·5—1·0 g. of sodium hydroxide and 1—2 g. of sodium carbonate per litre, the precipitate being allowed to settle, and 1000 c.c. of the supernatant clear liquid

evaporated to dryness after acidification with hydrochloric acid. The residue is then dissolved in 25 c.c. of water, filtered free from silicic acid, and the sulphuric acid estimated as previously described (J., 1920, 331 A, 584 A).—G. F. M.

Indican (indoxyl potassium sulphate); Detection of very small quantities of —— in water as an aid to hygienic water analysis. A. Jolles. Ber. Deuts. Pharm. Ges., 1920, 30, 421—442.

The presence of indican in a water, even in the merest traces, is a certain indication of previous contamination with animal excretions, and as its detection by chemical means is very simple and not interfered with by the commonly occurring constituents of natural waters, excepting nitrites, which, however, are readily eliminated by means of Mohr's salt (ferrous ammonium sulphate), its presence or absence forms an excellent criterion for the judgment of a water from the hygienic standpoint. The test is performed as follows: 3—4 l. of the water is evaporated to 250 c.c., and if nitrites are present 3 g. of Mohr's salt is added for every 0·1 g. of nitrite per litre of the original water. The evaporation is then continued to 10 c.c., and to the filtered solution 1 c.c. of 5% alcoholic thymol or α-naphthol solution, and 10 c.c. of fuming hydrochloric acid containing 5 g. of ferric chloride per litre are added. After keeping for 15 mins. with occasional shaking the indolignone colouring matter which will have been formed if indican was originally present, is extracted by careful shaking with 4 c.c. of chloroform. A reddish or bluish violet coloration of the chloroform layer, however slight, is a certain proof of the presence of indican and of the previous contamination of the water with animal excreta.—G. F. M.

Air containing toxic gases; Purification of ——. A. Desgrez, H. Guillemard, and A. Savès. Comptes rend., 1920, 171, 1177—1179.

Various spray fluids sprayed in with a Vermorel sprayer are recommended for neutralising different toxic gases. For chlorine a liquid containing 220 g. of sodium thiosulphate, 175 g. of sodium carbonate, and 1000 c.c. of water is recommended. For a mixture of carbonyl chloride and chlorine a 12% solution of sodium carbonate is effective. A fluid containing 240 g. of sodium polysulphide and 140 c.c. of soap-boiler's lye in 1 l. is effective in neutralising chlorine, carbonyl chloride, chloromethyl chloroformates, acrolein, bromoacetone, cyanogen chloride, chloropicrin, and benzyl chloride, bromide, or iodide.—W. G.

Oligodynamic action of metals. D. Acél. Biochem. Zeits., 1920, 112, 23—26.

Water treated with metallic silver has been shown by means of ammonium sulphide and by means of potassium chromate to contain silver. It was also demonstrated that if the dissolved silver was removed the water lost its oligodynamic action (*cf.* J., 1920, 702 A). The author therefore concludes that the oligodynamic action of silver is due entirely to the solubility of the metal in the water.—S. S. Z.

Patents.

Sewage sludge or the like; Method and means for reducing the percentage of water in ——. L. Linden. E.P. 153,335, 11.8.19.

Sewage sludge is run into settling chambers provided with upright revolving arms or with compressed air inlets, or with both, with the object of violently agitating the sludge so as thoroughly to incorporate any remains of a precipitant added previously. Additional precipitants may be added to the sludge, and after continuing the agitation for, say, five minutes, it is suddenly stopped. The heavy sludge sinks rapidly and completely. The supernatant liquid is drawn off at the top of the chambers, and the sludge from openings at the bottom.—J. H. J.

Waste liquors; Method of and apparatus for treating ——. C. L. Peck, Assr. to The Dorr Co. U.S.P. 1,357,587, 2.11.20. Appl., 1.12.19.

Waste liquid containing suspended solids is submitted to a combined process of sedimentation and flotation, the deposited and floating solids being both worked mechanically towards a common discharge region, whence they are removed together. —J. H. J.

Waste organic substances; Apparatus and process for treating ——. A. Maclachlan. U.S.P. (A) 1,359,085 and (B) 1,359,086, 16.11.20. Appl., 23.11.18 and 6.6.19.

(A) A tank in which the material is treated is connected with a chamber in which sulphur is burned, and this chamber is connected with another which is open to the air; a steam injector is inserted in the pipe connecting the sulphur chamber with the treatment chamber, so that sulphur dioxide and air may be introduced into the material. (B) Material containing fat is subjected to the action of sulphur dioxide and steam in order to cause separation of the fat.—W. P. S.

Insecticide. E.P. 154,057. *See* XVI.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Opiums; Content of ammonium salts in various ——. J. L. Thomson. Pharm. J., 1920, 105, 550.

Ammonium salts in small amounts are a normal constituent of opium. The analysis of a large number of samples of Turkish opium showed an average content of 0·22% of ammonia, of Indian opium 0·21%, and of Persian opium 0·18%. The fluctuations in amount were greatest in Turkish opium, *viz.*, from 0·09% to 0·47%.—G. F. M.

Opium; Effects of prolonged heating and of aqueous extraction on ——. A. M. Macmillan and A. Tingle. Amer. J. Pharm., 1920, 92, 810—815.

Opium when heated lost weight steadily, no sign of constancy being observed even after heating for 576 hrs. at 98°—100° C. At the same time there was a diminution in the morphine content, Persian opium losing more than 30% of its morphine in 96 hrs., but no more when the heating was continued for 288 hrs., whilst Indian opium lost only 3% in 96 hrs., but continued to lose progressively even after 576 hrs., when a 30% diminution in morphine content had been observed. The above results are at variance with those recorded by Annett and Singh (J., 1918, 315 T). The prolonged heating of crystallised morphine even for 8 days had no appreciable effect on the basicity beyond that due to the expulsion of the water of crystallisation. Morphine cannot be completely removed from opium by water extraction. Even under the drastic treatment of boiling for 16 hrs. in a Soxhlet extractor the residue still contained 2% of the total morphine originally present, whilst a further 9% had been destroyed by the boiling.—G. F. M.

Opium assay. A. J. Jones. Pharm. J., 1920, 105, 550—551.

The author criticises Dott's method (J., 1920, 347 A) and suggests the modification that 10 g. of opium be triturated with 3 g. of lime and 88 c.c. of water. This will give a dilution of the opium of 1 pt. in 9 fluid pts., and if the filtrate is diluted with one-

ninth of its volume of alcohol-ether mixture and again filtered the resulting filtrate will be exactly 1 in 10 dilution. 50 c.c., representing 5 g. of the opium, is then taken for the assay. A somewhat similar scheme is adopted for the direct assay of the wet gum.—G. F. M.

Digitalis; Chemistry of ——. H. C. Hamilton. J. Ind. Eng. Chem., 1920, **12**, 1180—1181.

THE author has isolated from digitalis extract two active principles, one being soluble in chloroform and the other insoluble, but there appears to be a tendency for the soluble substance to become less soluble on repeated applications of the solvent. Experiments on frogs showed that the chloroform-insoluble substance had the greater physiological action.—W. P. S.

Gentian preparations; Preservation of ——. M. Bridel. J. Pharm. Chim., 1920, **22**, 411—418.

THERE was no appreciable loss of carbohydrates in powdered gentian when this was kept for nine years, but the gentiopicrin disappeared entirely; the powder, however, still contained a glucoside hydrolysed by emulsin. The sugars remained unaltered in gentian extract, but diminished considerably in tinctures during the same period; the gentiopicrin also decreased in the tinctures, a tincture prepared with 60% alcohol being quite free from this substance after the lapse of nine years. This tincture contained a glucoside having the characters of β-ethylglucoside.—W. P. S.

Latex of Lactarius vellereus. J. Zellner. Z. physiol. Chem., 1920, **111**, 293—296.

THE latex of *Lactarius vellereus* consists mostly of water (80·5%) and a mixture of stearic acid and a resin (14·65%). The latter fraction can be extracted from the dried latex with ether, from which the stearic acid crystallises out on concentration and the resin remains in the mother liquor. Mannitol, dextrose, mineral substances, and proteins make up the rest of the latex.—S. S. Z.

Yeast nucleic acid. H. Steudel and E. Peiser. Z. physiol. Chem., 1919, **108**, 42—50.

A SAMPLE of commercial yeast nucleic acid with a ratio of P:N=1:1·77 was fractionated by means of lead acetate, sodium carbonate, and barium acetate into five fractions with varying P:N ratio. As the reactions employed in the fractionation were not drastic enough to break up the nucleic acid molecule the authors conclude that the substance was a mixture of several compounds. One of these fractions with a ratio of P:N=1:2·09 on analysis gave results corresponding to the formula

$$(C_{29}H_{39}O_{23}N_{13}P_3)_2Ba_3$$

for the barium salt of yeast nucleic acid.—S. S. Z.

Nucleic acids; New methods for preparation of ——. R. Feulgen. Z. physiol. Chem., 1920, **111**, 257—272.

THE nucleoprotein from pancreas was prepared by digesting the minced organ with hot water, treating the aqueous extract with sodium hydroxide, filtering, and precipitating with 96% alcohol after neutralising with acetic acid. The nucleoprotein was hydrolysed with sodium hydroxide and the mixed nucleic acids precipitated with 96% alcohol; these were purified by precipitation with alcohol in alkaline solution. The two nucleic acids were separated by salting out the sodium salt of guanylic acid with sodium acetate. The tertiary salt of guanylic acid was prepared by treating the secondary sodium salt of the acid with sodium hydroxide and precipitating with 96% alcohol. —S. S. Z.

Nucleic acids; New method of cleavage for ——. H. Steudel and E. Peiser. Z. physiol. Chem., 1920, **111**, 297—303.

SODIUM nucleate from the sperm of the herring was hydrolysed with calcium bisulphite solution prepared by passing sulphur dioxide through a 3% calcium chloride solution at 120°—130° C. for two hours. The resulting products of hydrolysis were precipitated with calcium acetate and purified by various precipitations. From the phosphorus and nitrogen determinations it was found that the substance thus isolated was identical with thymic acid. On hydrolysis with sulphuric acid under a reflux condenser thymin was obtained from it. The above method affords a means of preparing thymic acid with comparative ease, and the acid thus obtained shows great stability. After more than a year it retained its white colour, solubility in water, and power of reducing Fehling's solution.—S. S. Z.

Hypnotics. Puyal and Montagne. Bull. Soc. Chim., 1920, **27**, 857—862.

WITH a view to studying the effect on their hypnotic properties of introducing a chlorine atom or a phenyl group into urethanes, the authors have prepared a series of such urethanes as follows: Ethyl- and propylchloroethyl carbinolurethanes, phenylmethyl-, phenylethyl-, phenylpropyl-, and phenylbutyl - carbinolurethanes, vinylethylcarbinolurethane, phenylvinyl-carbinolurethane, ethoxychloropropanolurethane, phenoxyethoxypropanolurethane, chloroethanolurethane, and cyclohexanolurethane.—W. G.

Saccharin; Reaction of ——. L. Thévenon. J. Pharm. Chim., 1920, **22**, 421—422.

TEN c.c. of 0·1% sodium nitrite solution and 6 drops of dilute sulphuric acid are added to 0·1 g. of saccharin dissolved in 25 c.c. of water; after a few minutes 0·1 g. of β-naphthol is also added. A bright-red coloration appears at once; the colour is stable and dyes wool and silk.—W. P. S.

Thiodiglycol; Action of —— *on silver salts.* C. Moureu and M. Murat. Chim. et Ind., 1920, **4**, 593—596.

THIODIGLYCOL easily dissolves most silver salts, and it is not possible to precipitate the whole of the silver chloride from its solution in thiodiglycol by the addition of water. If present, therefore, thiodiglycol prevents the accurate estimation of chlorides volumetrically either by the chromate or thiocyanate methods of titration with silver nitrate. In the estimation of mustard gas (dichloroethyl sulphide) by titrating with silver nitrate the hydrochloric acid liberated by hydrolysis, the presence of thiodiglycol is therefore a source of error. The amount of the error increases with the amount of thiodiglycol present.—W. G.

Neosalvarsan [salvarsan, etc.]; Determination of arsenic in ——. A. Kircher and F. von Ruppert. Ber. Deuts. Pharm. Ges., 1920, **30**, 419—421.

FROM 0·2 to 0·3 g. of salvarsan (or its derivatives) is boiled with 20 c.c. of sulphuric acid and 15 g. of potassium sulphate in a 500 c.c. round flask connected with a bulb absorption tube containing a little water. When all the organic matter has been destroyed the absorption bulb and tube are rinsed out into the flask and the liquid is diluted to about 250 c.c., boiled for 5 mins. to expel sulphur dioxide, partially neutralised with sodium hydroxide, and dilute iodine solution added, drop by drop, in presence of starch to oxidise the last traces of sulphur dioxide. The solution is then decolorised with a few drops of thiosulphate, and after saturation with powdered sodium bicarbonate, the arsenious oxide is titrated with $N/10$ iodine (1 c.c. = 0·003748 g. As). It is advisable to perform a blank experiment at the same time.—G. F. M.

Triphenylarsine and diphenylarsenious salts. W. J. Pope and E. E. Turner. Chem. Soc. Trans., 1920, 117, 1447—1452.

The best conditions for the preparation of triphenylarsine are realised by the action of 57 g. of sodium in wire or slices on a mixture of 136 g. of chlorobenzene and 85 g. of arsenic trichloride in presence of 300 c.c. of benzene. The sodium is preferably covered first with the benzene containing 1—2% of ethyl acetate, and left for 30 mins to activate the metal, after which the other reagents are slowly run in, the mixture being finally boiled for several hours under a reflux condenser. The yield, calculated on the chlorobenzene, amounts to about 90% of the theoretical. When triphenylarsine (30·6 g.) is heated at 350° C. under atmospheric pressure with arsenic trichloride (25·5 c.c.), a mixture of phenylarsenious dichloride and diphenylarsenious chloride is produced which can be readily separated by fractional distillation *in vacuo* (*cf.* E.P. 142,880; J., 1920, 527 A). Diphenylarsenious chloride is readily converted into the oxide, $[(C_6H_5)_2As]_2O$, by boiling an alcoholic solution with alcoholic potassium hydroxide. It is a colourless crystalline solid, m.p. 89°—91° C., and on heating with hydrobromic or fuming hydriodic acid at 100° C. in a sealed tube it yields diphenylarsenious bromide, m.p. 55°—56° C., and diphenylarsenious iodide, m.p. 45°—46° C., respectively. —G. F. M.

Selenium monochloride; Interaction of ethylene and ——. H. W. Bausor, C. S. Gibson, and W. J. Pope. Chem. Soc. Trans., 1920, 117, 1453—1456.

Ethylene reacts with selenium monochloride to give ββ'-dichloroëthyl selenide dichloride and selenium: $2CH_2:CH_2+2Se_2Cl_2=(CH_2Cl.CH_2)_2SeCl_2+3Se$. It seems probable that the reaction proceeds initially as with sulphur monochloride, but that the selenide is further acted on by selenium monochloride with liberation of selenium. The selenium monochloride was prepared by the action of dry hydrogen chloride on a solution of selenium in fuming sulphuric acid (15% SO_3), and was treated with ethylene in presence of benzene as diluent. After filtering off the precipitated selenium and distilling off the benzene, ββ'-dichloroethyl selenide dichloride remained as white needles and after recrystallisation from benzene formed long slightly hygroscopic colourless prisms, m.p. 122·5° C. It is freely soluble in water, half the chlorine present being hydrolysed to hydrogen chloride. On passing sulphur dioxide into the cold aqueous solution an oil separates, which crystallises to a mass of colourless needles, m.p. 23°—25° C., possibly ββ'-dichloroethyl selenide. —G. F. M.

Turpentine; Thermal decomposition of —— *with particular reference to the production of toluene and isoprene.* S. A. Mahood. J. Ind. Eng. Chem., 1920, 12, 1152—1155.

Although turpentine is a possible source of toluene it does not give a sufficiently large yield either of toluene or isoprene to make it a practical source of these products under ordinary conditions.—W. P. S.

Juniperus phœnicea; Essential oil extracted from the berries of —— *of Sardinia.* E. Puxeddu and F. Vodret. Gaz. Chim. Ital., 1920, 50, II., 245—257.

When distilled with water, the macerated berries of *Juniperus phœnicea* yield 2·5% of essential oil, four-fifths of this amount distilling over during the first hour while the remainder requires about 5 hrs.; the preliminary maceration with water should last at least two days. The oil is neutral, colourless and transparent, but turns slightly yellow under the influence of light. Its taste resembles that of camphor and it has a marked aromatic odour, while when rubbed between the hands it emits the odour of turpentine. It burns with emission of dense smoke and resinous odour. It has sp. gr. 0·8658 at 15° C.; $[\alpha]_D^{24}=+16·84°$; viscosity, $\eta=1·7259$ at 18·5° C.; solubility at 27° C., zero in 70% or 80% alcohol, 1:16 in 90% alcohol; refractive index, 1·4675 at 20° C. for ordinary light; saponification value, 14—15; acid value, 2·49; acetyl value, 35; aldehydes and phenols, absent; Maumené value, 136·8°; iodine value (Hübl), 285·53, but varying values are obtained if the amount of iodine employed in the test is varied; bromine value, 264·55. The essential oil was subjected to repeated fractional distillation under diminished pressures, the principal fraction, b. pt. 74° C. under 30 mm. pressure, having sp. gr. 0·8543 at 25° C., refractive index 1·4644, and $[\alpha]_D^{25}=+23·94°$.—T. H. P.

Essential oil of jasmine; Extraction of the ——. J. Nivière. Bull. Soc. Chim., 1920, 27, 862—865.

The fact that a much greater yield of superior oil is obtained from jasmine by the method of "enfleurage" using animal fats, than by extraction with volatile solvents, has been explained by Charabot and Gatin (*La parfum chez la plante*, Paris, 1908) on the basis of the decomposition of glucosides with production of oil during the enfleurage. In support of this, it is now shown that if the jasmine flowers are submited to a preliminary hydrolysis by acid or enzymes before extraction with solvents, the yield of oil is increased. The physical and chemical properties of the oil extracted from the hydrolysed flowers differ somewhat from those of the oil extracted from the non-hydrolysed flowers.—W. G.

Cholesterol. Steinkopf and others. *See* IIA.

Methyl alcohol. Heuser and Schmelz. *See* V.

Patents.

Pyrophosphate casein compounds; Process for the manufacture of colloidally soluble metal ——. H. R. Napp. From F. Hoffmann-La Roche & Co. E.P. 154,112, 28.2.20.

Casein (66 pts.) is dissolved in an aqueous solution of 112 pts. of sodium pyrophosphate, and a solution of a metal salt, *e.g.*, 156 pts. of 4*N* calcium chloride solution, or 195 pts. of 23% ferric chloride solution, is added with agitation. The metal compound is precipitated by the addition of alcohol, and separated by filtration, washed, and dried at 50° C. —L. A. C.

Acetic acid; Manufacture of ——. British Cellulose and Chemical Manufacturing Co., M. Soller, and J. Hotz. E.P. 154,304, 21.8.19.

The oxidation of liquid acetaldehyde to acetic acid is accomplished by using china clay, with or without the addition of sodium acetate, as a catalyst, and passing free oxygen into the agitated mixture at 10°—20° C.—D. F. T.

Acetic acid; Apparatus for the manufacture of ——. H. W. Matheson. E.P. 154,368, 9.9.19. (*Cf.* E.P. 132,558; J., 1919, 846 A.)

Acetaldehyde is treated with air in the presence of a catalyst in an aluminium-lined vessel, which contains two water-cooled metal coils for the regulation of the temperature and is fitted with two condensers, water-cooled and brine-cooled respectively, in series, the condensed product from each being returned to the reaction vessel by means of a connexion below the level of the liquid.—D. F. T.

Acetic acid; Manufacture of ——. H. Dreyfus. E.P. 154,680, 28.8.19.

The inorganic matter present in animal charcoal forms a satisfactory catalyst for the oxidation of liquid acetaldehyde to acetic acid; the calcium and magnesium phosphates are the most effective constituents. The residue obtained by heating animal charcoal in the air, or artificially prepared mixtures of the chief constituents of such residues, can therefore be applied to accelerate the oxidation process, preferably with the addition of sodium acetate.
—D. F. T.

Chloroform; Manufacture of ——. M. Phillips. U.S.P. 1,359,099, 16.11.20. Appl., 13.8.20.

The alcoholic product obtained by passing unsaturated hydrocarbons rich in propylene into sulphuric acid, and afterwards hydrolysing the alkyl sulphates, is treated with chloride of lime (bleaching powder).—J. H. L.

Sodium and potassium formate; Production of —— from calcium formate. Elektrochem. Werke G.m.b.H., Bosshard, and D. Strauss. G.P. 325,638, 16.5.19.

On treating calcium formate (12 mols.) with sodium or potassium sulphate (10 mols.), 96% of the latter undergoes conversion into formate; the remaining 4% of alkali sulphate is of no disadvantage in the subsequent fusion to oxalate, whilst the excess of calcium formate on interaction with alkali oxalate or carbonate yields alkali formate, the calcium simultaneously being rendered insoluble.—D. F. T.

Perhydronaphthylphenylmethane - o - carboxylic acids; Preparation of ——. R. Willstätter. G.P. 325,714, 23.4.19.

Perhydronaphthylphenylmethane - *o* - carboxylic acid, $C_{18}H_{30}O_2$, is obtained by the reduction of naphthoyl-*o*-benzoic acid with hydrogen in the presence of a catalyst, such as platinum, palladium, or nickel, or, in particular, an oxide of the last-named metal; it exists in four modifications—the α-modification, rhombic tablets, m.p. 129° C.; β-form, rhombic tablets, m.p. 114° C.; γ-form, prisms, m.p. 94° C.; δ-form, a viscous syrup. These acids are of value as substitutes for the higher fatty acids. If naphthoylbenzoic acid is heated with a zinc-copper couple and an aqueous solution of ammonia, no perhydro-acid results, the product being naphthylphenylmethane-*o*-carboxylic acid.—D. F. T.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

[*Photographic*] *development; Some results of recent investigations on the theory of* ——. A. H. Nietz. Communication No. 100 from Eastman Kodak Research Lab. Phot. J., 1920, **60**, 280—291.

The reduction potential of a developer may be measured by the amount of bromide required to produce a given depression in the density or by the concentration of bromide against which the developer can just develop. If the straight line portions of a series of curves connecting the log exposure (log E) with the density (D) of a plate for a series of times of development with the same bromided developer be continued, they will be found to meet at a point below the log E axis. If this point be a, b, then $D=\gamma(\log E-a)+b$, which also follows mathematically on the experimental proof that if density be plotted against degree of development (γ) the locus is a straight line, $D=\theta(\gamma-A)$, from which $b=-A\theta$ and $a=\log E-\theta$. The values of a and θ are found to be constant for a long range of bromide concentrations, while b is proportional to log bromide concentration over a considerable range. Plotting b against log C (concentration), if C_0 is the intercept on the log C axis for the bromide concentration which just depresses the density, then d (density depression) $=b=m(\log C-\log C_0)$. The value of m is 0·5, practically independent of developer and of emulsion, so that C_0 is a measure of the reduction potential. The values of reduction potential are given for 18 developers taking that for quinol as 1. Rate of development is found experimentally to be proportional not only to the amount of work still waiting to be done ($D_\infty-D$) but also inversely to the time from first appearance of the image, which leads to a more accurate method of arriving at maximum density by plotting $\log D_\infty/(D_\infty-D)$ against log t, choosing D_∞ by trial and error to obtain a straight line (see also Bloch, Phot. J., 1917, 57, 60; J., 1917, 353). It is suggested that, except for quinol and substituted quinols, the maximum density is higher the greater the reduction potential. The effect of bromide on maximum density is the same as the effect on density in the earlier stages of development. Maximum contrast obtainable is not affected by bromide, but the practical maximum contrast is affected by the reduction of fog. The effect of bromide on velocity of development is only in the early stages of development—the period of induction—after which the velocity is the same with or without bromide. The equations deduced for density and rate of development are utilised in the determination of speed and of maximum contrast. Speed of emulsion and fogging power of the developer are not apparently functions of the reduction potential, and fog formation does not appear to follow the same law as normal density development. Comparing the constitutional formulæ of the developers studied it appears that aminophenols are the most energetic hydroxyphenols the next and amines the least; substitution of a single methyl group in the amino group or in the nucleus increases the energy, but two methyl groups are not always still more effective. The introduction of a second amino group increases the potential while conversion to a glycine or introduction of CH_2OH lowers it; these results are of partial application only as the effect of group position has not been worked out.—B. V. S.

Phenols; Tautomerism of ——. *I. Quinol.* W. Fuchs and B. Elsner. Ber., 1919, **52**, 2281—2286.

Quinol is capable of reacting in its tautomeric form (as an unsaturated cyclic ketone) with sodium hydrogen sulphite. The sodium salt of cyclohexane-1.4-diol-1.2.4-trisulphonate has been isolated from the reaction product and found to function as a photographic developer, which may possibly exist in the ordinary quinol developing solution.

Feeble conductors of electricity; A new property of substances which are ——. G. Reboul. Comptes rend., 1920, **171**, 1052—1055.

If in a dark room a photographic plate is covered with a sheet of paper which is in turn put in contact for 24—48 hrs. with two electrodes having a potential difference of 1000 volts, on developing the plate the fibres of the paper are reproduced and the equipotential lines are roughly marked. Coarse-grained paper gives a better result than fine-grained paper. The impression on the plate is much stronger if the conductivity of the paper is increased by damping it and then allowing it to dry in the air. The effect disappears almost completely and is confined to the neighbourhood of the electrodes if the paper is perfectly dry. It is apparently necessary that the material between the

photographic plates and the electrodes shall be a feeble conductor and that it shall be heterogeneous or present superficial discontinuities such as might be caused by superficial incisions in the paper.
—W. G.

Cyanine dyes. Mills and Hamer. *See* IV.

XXII.—EXPLOSIVES; MATCHES.

Explosives; Velocity of decomposition of high —— in a vacuum. I. R. C. Farmer. Chem. Soc. Trans., 1920, 117, 1432—1445.

THE relative stability of high explosives can be measured by determinations of the velocity of decomposition, as indicated by the rate of evolution of gas, on heating in a vacuum. The apparatus employed consists of a lagged copper bath provided with a reflux condenser, and six orifices in the lid into which steel tubes are loosely fitted to guard against damage by explosion. They are packed round with copper filings to give good contact with the bath. Special precautions are taken to guard against failure of the condenser water supply during the prolonged heating. The glass tubes containing weighed quantities of the explosive under examination are each provided with a ground-in stopper leading to a capillary manometer tube which terminates in a cup containing sufficient mercury to fill the upright limb of the capillary. The tube is exhausted through the cup and the mercury rising in the capillary forms automatically a seal, and its height records the pressure within the tube. The apparatus is then placed in the heating bath, the material is thoroughly dried by heating to a temperature at which no measurable decomposition occurs (say, 80° C.), and again exhausted, and finally heated at the desired temperature, whilst readings of the pressure are taken from time to time from which the evolved gas volume is deduced. It was found that all explosives undergo a gradual decomposition at temperatures considerably below their ignition points. The velocity is highly affected by temperature and by the catalytic action of impurities. The trinitro aromatic compounds are in general much more stable than the nitric ester explosives. The dinitro-compounds show scarcely any measurable decomposition, whilst on the other hand the nitro-amines such as "tetryl" are less stable. The relative stability is roughly indicated by the temperatures at which the gas evolution amounts to 1 c.c. per g. in 100 hrs., *viz.*, trinitrobenzene 190°—195° C., trinitrophenol 150°—155° C., 2.4.6-trinitrotoluene 135°—140° C., tetryl 115°—120° C., nitrocellulose 100° C. The stability of T.N.T. is not appreciably affected by the addition of small quantities of isomeric trinitrotoluenes, whilst mixtures of picric acid and T.N.T. show an even slower rate of decomposition than T.N.T. alone. The addition of an unsaturated substance (castor oil) strongly depressed the stability of both picric acid and T.N.T.—G. F. M.

Umbrite; A new explosive, ——: its use in agriculture. G. Tommasi. Ann. R. Staz. Chim.-Agrar. Sperim., 1917—1919, II., 9, 75—94.

UMBRITE A, containing 49 pts. of nitroguanidine, 38 of ammonium nitrate, and 13 of silicon, is suitable for artillery shells, while umbrite B, containing 37·5 pts. of nitroguanidine, 49·4 of ammonium nitrate, and 13·1 of silicon, which has a greater disruptive power, serves well for bombs, for mining purposes, and for loosening the soil. These explosives are but slightly hygroscopic and retain unaltered their explosive power even when they contain a certain proportion of water.—T. H. P.

XXIII.—ANALYSIS.

Adsorption in analytical chemistry; Importance of ——. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 1510—1529.

THE adsorbing action of filter paper, at least so far as electrolytes are concerned, is to be ascribed to the ash content, which functions as a calcium-permutite, in which the calcium ion may be replaced by another positive ion, which thus becomes fixed by the paper. Thus anions are not adsorbed, whilst equivalent quantities of positive ions are taken up, corresponding to the alkalinity of the ash. The capillary action of filter paper, as manifested by the sucking up of liquids and solutions, appears not to be a pure adsorption phenomenon. (*Cf.* J.C.S., Jan.)—S. I. L.

Acids; Adsorption of —— by filter-paper. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 1571—1577.

THE amount of acid taken up by filter-paper was found to be constant for each kind of paper, and to be exactly equivalent to the alkalinity of the ash. In one case the adsorption law was found to hold for several acids within certain limits of dilution. (*Cf.* J.C.S., Feb.)—S. I. L.

Conductometric titrations; Application of —— in analysis. I. M. Kolthoff. Chem. Weekblad, 1920, 17, 694—701. (See J., 1920, 529A, 530A, 558A, 717A, 733A, 735A, 767A.)

LIMITS are given for the dissociation constants of acids and bases which can be determined by the conductivity method, and modifications are suggested by means of which titrations of weak and strong acids and bases, alone, or in presence of one another and of salts, etc., can be carried out. (*Cf.* J.C.S., Feb.)—S. I. L.

Permanganate titrations; Catalysis of ——. P. H. Segnitz. J. Ind. Eng. Chem., 1920, 12, 1196—1197.

BY the addition of manganous sulphate solution in permanganate titrations, the reaction velocity is increased, and the time required can be reduced from 35 mins. to 8 secs. in the case of hydrogen peroxide-permanganate titrations and from over 1 hr. to 6 mins. in that of cold oxalate-permanganate titrations. The accuracy of the end-point is not affected.

Potassium; Determination of —— by the Lindo-Gladding method. H. C. Moore and R. D. Caldwell. J. Ind. Eng. Chem., 1920, 12, 1188—1189.

WHEN dealing with pure potassium salts, the same results are obtained whether the potassium platinichloride precipitate is washed with 80% alcohol or 95% alcohol; sodium salts, however, if present, are more soluble in the 80% alcohol, and this alcoholic solution of sodium salts has a distinct solvent action on the potassium platinichloride, causing low results for potassium to be obtained.—W. P. S.

Barium; Gravimetric determination of —— as barium sulphate. L. W. Winkler. Z. angew. Chem., 1920, 33, 299.

THE neutral solution of the barium salt is treated with 1 g. of ammonium chloride and 1 c.c. of $N/1$ hydrochloric acid, boiled, and a slight excess of ammonium sulphate solution is added. The precipitated barium sulphate may be weighed either after drying or after incineration. The weight of the dry precipitate should be decreased by 0·16 mg. and that of the ignited precipitate increased by 0·6 mg. for quantities of precipitate of about 0·3 g.
—W. P. S.

Calcium; Determination of —— in the presence of phosphates. J. F. Breazeale. J. Assoc. Off. Agric. Chem., 1920, 4, 124—134.

STARTING with, say, a plant ash containing calcium, magnesium, an excess of phosphates, and some iron, but no manganese, the ash is dissolved in dilute hydrochloric acid, the solution boiled and made slightly alkaline with ammonia. A saturated solution of oxalic acid is then added until the liquid is just acid. This acid will dissolve the phosphates of iron and magnesium and convert the calcium phosphate into calcium oxalate. The solution is again made slightly alkaline with ammonia and then slightly acid with oxalic acid. The liquid is allowed to stand in a hot place until the precipitate settles and the precipitate is dealt with in the usual manner. If manganese is present it will be precipitated as oxalate along with the calcium oxalate. In this case the precipitate, after being filtered off and washed, is dissolved in excess of hydrochloric acid, the solution is made alkaline with ammonia and a little ammonium oxalate is added. The calcium is precipitated as oxalate, while the manganese remains in solution. Calcium oxalate is not soluble in oxalic acid solution at the ordinary temperature, but is appreciably soluble in boiling 30% acid. It is not soluble in solutions of ammonium or sodium salts in the presence of oxalic acid, but it is markedly soluble in solutions of sodium nitrate, chloride, or sulphate alone at the ordinary temperature and still more so in boiling solutions.—W. G.

Manganese in presence of phosphates; Detection of ——. T. Sabalitschka and W. Erdmann. Ber. Deuts. Pharm. Ges., 1920, 30, 443—445. (*Cf.* Schmidt, J., 1920, 530 A.)

A CRITICISM of Schmidt's analytical method (*loc. cit.*). In presence of an excess of barium phosphate manganese is completely precipitated as phosphate by excess of ammonia, and in the further examination of the precipitate after removal of the phosphoric acid a flocculent precipitate of manganese oxalate is obtained with ammonium oxalate which is very liable to be mistaken for calcium. In presence of calcium phosphate some of the manganese is precipitated in a similar way by ammonia, whilst the rest remains in solution with the zinc in the normal way. It is further pointed out that only by leading hydrogen sulphide into the ammoniacal solution, and not by the simple addition of ammonium sulphide, is manganese precipitated entirely as sulphide from its solutions in presence of phosphates or oxalates.—G. F. M.

Bismuth; Gravimetric determination of —— as phosphate, and its application to ore analysis. W. R. Schoeller and E. F. Waterhouse. Analyst, 1920, 45, 435—439.

THE cold bismuth solution, containing nitric acid but no chlorides, is treated with ammonia until a slight permanent precipitate is obtained; 2 c.c. of concentrated nitric acid is then added, the solution boiled, and 10% diammonium phosphate solution is added slowly. About 40 c.c. of the phosphate solution is required for 0·2 g. of bismuth, 60 c.c. for 0·4—0·5 g. The mixture is diluted to 400 c.c. with boiling water, the precipitate collected after 15 mins., washed with hot 3% ammonium nitrate solution containing a few drops of nitric acid per litre, dried, and ignited gently. The weight of $BiPO_4 \times 0·6865$ gives the weight of bismuth. The method may be applied to the analysis of ores; the bismuth is separated from lead by precipitation with iron wire (*cf.* J., 1900, 389), copper, arsenic, and antimony are separated by extraction of the sulphides with sodium cyanide and sulphide, and the bismuth sulphide is converted into phosphate. —W. P. S.

Arsenic; General method for the detection and estimation of ——. **Kohn-Abrest. Comptes rend., 1920, 171, 1179—1182.**

FOR the estimation of arsenic in animal or human organs, physiological fluids, or foodstuffs, the material is calcined with a mixture of magnesium nitrate and oxide, using 35 c.c. of a 20% solution of magnesium nitrate and 1 g. of the oxide, the mixture being dried at 110° C. before calcining. The arsenic in the ash is determined either by Marsh's method or by reduction to arsenite and titration with standard iodine solution.—W. G.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Barytes Consolidated, Ltd., and Elliott. Separating fines from ground materials. 749. Jan. 7.

Bramwell. Filtration of liquids. 662. Jan. 6.

Broadbent, and Broadbent and Sons. Centrifugal machines. 36,454. Dec. 30.

Chenard. Fractional distillation. 167. Jan. 3. (Fr., 3.1.20.)

Cook. Chemical and physical synthesis. 36,612. Dec. 31.

Farbenfabr. vorm. F. Bayer u. Co. Separating or isolating organic gases etc. 464. Jan. 5. (Ger., 3.11.16.)

Fauth. Filter plates. 801. Jan. 7. (Ger., 3.9.19.)

Freyn, Brassert, and Co. Method of gas-washing. 365. Jan. 5. (U.S., 28.6.15.)

Giesecke. 36. *See* X.

Kampf. Washing and treating artificial materials. 390. Jan. 5. (Ger., 19.4.19.)

Langer. 454. *See* II.

Lilienfeld. Manufacture of colloidally-soluble substances and suspensions or emulsions. 786. Jan. 7. (Austria, 1.8.19.)

Logan. Regulating specific gravity of solutions. 781. Jan. 7. (U.S., 12.7.16.)

McCubbin. Treating smoke, fumes, etc. 36,300. Dec. 29.

Martin. Separating solids from gases. 291. Jan. 4. (Ger., 21.11.19.)

Martin. Conveying, and wetting material to be conveyed. 292. Jan. 4. (Ger., 24.12.19.)

Moulin. Apparatus for diffusion of essence or volatile liquids. 36,644. Dec. 31. (Fr., 14.6.19.)

Nitrogen Products Co. Furnaces. 351. Jan. 5. (U.S., 27.1.19.)

Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Apparatus for effecting continuous crystallisation. 883. Jan. 7. (Norway, 17.9.14.)

Ondra. Concentrating, classifying, or separating pulverulent material. 300. Jan. 4.

Plauson and Vielle. 36,552. *See* II.

Plauson and Vielle. Manufacture of dispersoids, colloid powder, and masses therefrom. 36,554. Dec. 31. (Ger., 29.8.18.)

Still. Saturators for producing solid salts by treating gases with liquid. 1097. Jan. 8. (Ger., 8.8.19.)

Sturtevant Co. Drying-apparatus. 353. Jan. 5. (U.S., 8.12.13.)

COMPLETE SPECIFICATIONS ACCEPTED.

15,601 (1919). Sauer. Purifying and separating or filtering liquids. (155,609.) Dec. 31.

15,606 (1919). Sauer. Filtering, decolorising, and purifying liquids, juices, etc. (155,611.) Dec. 31.

17,931 (1919). Elliott. Removal of gases from liquids. (155,864.) Jan. 12.

24,704 (1919). Akkerman. Process for drying liquids. (155,927.) Jan. 12.

9525 (1920). Littleton. *See* XVIII.

18,030 (1920). Krupp A.-G. Acid-resisting boilers, pipes, etc. (145,732.) Jan. 12.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Adam. Purification of coal gas. 296. Jan. 4.

Anderson and Meikle. Manufacture of briquettes. 36,336. Dec. 29.

Bamber and Parker. Producer-gas generators. 576. Jan. 6.

Bates. Flotation process of fuel production. 36,298. Dec. 29. (U.S., 23.3.20.)

Boocock and others. 515. *See* VII.

Chem. Fabr. Worms. 289. *See* III.

Cox. Gas plant. 36,396. Dec. 29.

Cravau. Coke ovens. 311. Jan. 4.

Daynes. Detection and measurement of gases. 1117. Jan. 8.

Dolbear. Treating oil shales. 218. Jan. 4.

Dutt and Dutt. Decolorising and treating mineral oils. 277. Jan. 4.

Erdmann. Obtaining paraffin and highly viscous lubricating oils from bituminous masses. 526. Jan. 6. (Ger., 22.1.18.)

Erdmann. Obaining paraffin from lignite tar, coal tar, or shale tar. 727. Jan. 7. (Ger., 5.8.18.)

Erdmann. Treatment of bituminous tars, mineral oils, tar distillates, etc. 728. Jan. 7. (Ger., 2.9.19.)

Erdmann. Obtaining highly viscous lubricating oils from peat tar. 729. Jan. 7. (Ger., 9.9.19.)

Everett and Salerni. Apparatus for distilling carbonaceous materials. 234. Jan. 4.

Farbw. vorm. Meister, Lucius, u. Brüning. Fuel for internal-combustion engines. 1096. Jan. 8. (Ger., 24.3.15.)

Freyn, Brassert, and Co. 365. *See* I.

Gewerkschaft ver. Constantin der Grosse. Continuous distilling oven for making gas and coke. 1093. Jan. 8. (Ger., 7.5.19.)

Halbergerhütte Ges. Treating plants for filtering combustible gases. 819. Jan. 7. (Ger., 29.4.14.)

Langer. Lubricating-oil emulsion. 409. Jan. 5. (Austria, 9.8.16.)

Langer. Manufacture of an oil emulsion. 453. Jan. 5. (Austria, 16.1.17.)

Langer. Lubricant for cylinders of steam engines etc. 454. Jan. 5. (Ger., 3.6.20.)

Georgs-Marien-Bergwerks- u. Hütten A.-G. Gas-producers. 36,659. Dec. 31. (Ger., 14.5.15.)

Plauson and Vielle. Extraction of carbonaceous substances or hydrocarbons. 36,464. Dec. 30. (Ger., 23.4.18.)

Plauson and Vielle. Manufacture of lubricating oils. 36,552. Dec. 31. (Ger., 12.12.19.)

Plauson and Vielle. Extraction of montan wax from bituminous coal. 36,464. Dec. 30. (Ger., 23.4.18.)

Plauson and Vielle. Obtaining and oxidising paraffins etc., and obtaining soaps. 36,553. Dec. 31. (Ger., 4.6.19.)

Roberts. Carbonisation of coal. 72. Jan. 3.

Summers. Coke ovens. 473. Jan. 5.

Turnbull. Briquetting coke. 1132. Jan. 8. (Ger., 28.6.16.)

COMPLETE SPECIFICATIONS ACCEPTED.

10,713 (1919). Coune. Gas washer and purifier. (155,859.) Jan. 12.

13,593 (1919). Soc. Franco-Belge de Fours à Coke. Horizontal coking-ovens. (127,590.) Jan. 12.

20,891 (1919). Broadbridge, Edser, Stenning, and Minerals Separation, Ltd. Production of coal briquettes. (155,875.) Jan. 12.

23,178 (1919). Macdonald, and Densified Peat Fuel and Products, Ltd. Treatment of peat. (155,895.) Jan. 12.

25,092 (1919). Wallwin. Gas-producers. (155,679.) Dec. 31.

8327 (1920). Pfeifer. Retort furnace for use in making gas. (156,029.) Jan. 12.

10,186 (1920). Marks (Soc. Franco-Belge de Fours à Coke). Coke ovens. (156,034.) Jan. 12.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Anderson and Atack. Fusion of organic substances with alkalis. 36,581. Dec. 31.

Chem. Fabr. Worms. Manufacture of anthraquinone and its derivatives. 157, 455, 457. Jan. 3 and 5. (Ger., 18.5.18, 1 and 27.12.19.)

Chem. Fabr. Worms. Manufacture of oxidation products of organic compounds. 286. Jan. 4. (Ger., 15.7.19.)

Chem. Fabr. Worms. Manufacture of constituents of low boiling-point from tar products, resins, mineral oils, etc. 289 and 456. Jan. 4 and 5. (Ger., 23.1 and 1.3.17.)

Erdmann. 727—729. *See* II.

Wohl. Oxidation of hydrocarbons. 257. Jan. 4. (Ger., 22.6.16.)

Wohl. Catalytic oxidation of organic compounds. 258. Jan. 4. (Ger., 18.12.16.)

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

British Dyestuffs Corp., Peacock, and Segaller. Manufacture of oxy and sulpho-oxy derivatives of anthraquinone. 36,536. Dec. 30.

Carpmael (Bayer u. Co.). Manufacture of azo dyes. 146. Jan. 3.

Chem. Fabr. Worms. 157, 455, 457. *See* III.
Glover and Martin. Manufacture of dyes. 575. Jan. 6.
National Aniline and Chemical Co. Disazo dye. 651. Jan. 6. (U.S., 1.7.19.)
Plauson and Vielle. Manufacture of oil-soluble dyestuffs. 688. Jan. 7.

COMPLETE SPECIFICATION ACCEPTED.

5267 (1920). Hart and Stewart. Production of dyestuffs. (155,726.) Dec. 31.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

British Cellulose and Chem. Manuf. Co., Dickie, and Palmer. Manufacture of artificial filaments, threads, and films. 275—6. Jan. 4.
Ehrenthal. Manufacture of cotton substitutes. 753—4. Jan. 7. (Ger., 8.8 and 24.11.19.)
Fabr. de Soie Artif. de Tubize. Spinning nitro-cellulose solution. 1094. Jan. 8. (Ger., 28.12.17.)
Harnist. Treating crude cellulose. 852. Jan. 7. (Fr., 6.7.14.)
Heigs and Müller. Treatment of highly-ligneous plants etc. 399. Jan. 5. (Ger., 13.2.14.)
Kampf. 390. *See*. I.
Leysieffer. Production of plastic bodies of cellulose ethers. 818. Jan. 7. (Ger., 10.1.20.)
Sinclair. Manufacture of artificial silk by the viscose process. 973. Jan. 8. (Belg., 20.12.19.)
Stein. Utilising concentrated waste sulphite liquor. 470. Jan. 5. (Ger., 18.9.19.)
Sturtevant Co. Paper-making. 354. Jan. 5. (U.S., 11.12.13.)

COMPLETE SPECIFICATION ACCEPTED.

31,191 (1919). Gillet et Fils. Treatment of vegetable fibres. (150,665.) Jan. 12.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Davies, Thomas, and Scottish Dyes, Ltd. Dyeing piece goods. 36,374. Dec. 29.
Mehler Segeltuchweberei A.-G. Waterproofing fabrics. 851. Jan. 7. (Ger., 23.4.16.)
Winkler. Waterproofing-composition. 592. Jan. 6. (Switz., 24.10.18.)

COMPLETE SPECIFICATION ACCEPTED.

6541 (1920). Kereszty and Wolf. Production of bleaching and disinfecting agents. (147,535.) Dec. 31.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Aluminium Co. Manufacture of aluminium chloride. 36,516. Dec. 30. (U.S., 26.5.20.)
Aschkenasi. Manufacture of perborates and disodium perphosphates. 757. Jan. 7. (Ger., 27.11.18.)
Aschkenasi. Manufacture of perborates. 758. Jan. 7. (Ger., 27.11.18.)
Blanc and Jourdan. Extraction of potash from leucite or leucitic rocks. 471. Jan. 5. (Ital., 5.1.20.)
Boocock, Wyld, and Holmes and Co. Recovery of ammonia from ammoniacal liquor. 515. Jan. 6.
Burke and others. 414. *See* XIII.
Chem. Fabr. Worms. Manufacture of metal salts. 155. Jan. 3. (Ger., 13.3.18.)
Harger, and Woodcraft Manuf. Co. Manufacture of hydrogen and mixtures of hydrogen and nitrogen. 36,456. Dec. 30.
Koppers Co. Manufacture of ammonium sulphate. 36,664. Dec. 31. (U.S., 10.5.18.)
Nitrogen Corp. Synthesis of ammonia. 732. Jan. 7. (U.S., 7.1.20.)
Nitrogen Products Co. Fixation of atmospheric nitrogen. 352. Jan. 5. (U.S., 5.7.19.)
Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Removing solid nitrogen oxides from refrigerating devices. 882. Jan. 7. (Norway, 14.10.18.)
Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Manufacture of concentrated nitrous gases. 884. Jan. 7. (Norway, 6.10.15.)
Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Converting nitrous gases into concentrated nitric acid. 885. Jan. 7. (Norway, 22.5.15.)
Shimadzu. Lead oxides, and manufacture of same. 36,519. Dec. 30.
Soc. l'Air Liquide. Synthesis of ammonia. 36,533. Dec. 30. (Fr., 30.12.19.)
Still. 1097. *See* I.

COMPLETE SPECIFICATIONS ACCEPTED.

11,184 and 11,186 (1919). Desachy. *See* XIII.
17,706 (1919). Barbet et Fils et Cie. Purification or argon and other rare gases of the atmosphere. (129,989.) Jan. 12.
23,505 (1919). Duparc and Urfer. Direct oxidation of ammonia. (133,041.) Jan. 12.
25,545 (1919). Mackay. Manufacture of lead sulphate. (155,945.) Jan. 12.
26,231 and 28,489 (1919). Hood. Purification of sulphur. (155,692.) Dec. 31.
32,397 (1919). Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Production of concentrated nitrous gases and nitric acid. (137,081.) Jan. 12.
4369 (1920). New Jersey Zinc Co. *See* XIII.
8471 (1920). Soc. l'Azote Française. Manufacture of ozone. (140,777.) Jan. 12.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Emery. Manufacture of pottery. 36,447. Dec. 30.
Rebuffat. Manufacture of refractory articles. 446. Jan. 5. (Ital., 27.2.20.)

COMPLETE SPECIFICATION ACCEPTED.

5760 (1920). Norton Co. Abrasive stone. (139,502.) Jan. 12.

IX.—BUILDING MATERIALS.

APPLICATION.

Dyson. Cements. 118. Jan. 3.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Agostini. Solder for aluminium etc. 658. Jan. 6. (Fr., 5.1.20.)
Giesecke. Sintering processes. 36. Jan. 3. (Ger., 20.12.17.)
Gregory, and Soc d'Utilisation des Combustibles Pulvérisés. Roasting minerals. 190. Jan. 4. (Fr., 19.10.20.)
Hanemann. Plating metal objects with steel. 1099. Jan. 8. (Ger., 22.12.17.)
Keller. Alloys, and resistance grids formed thereof. 123. Jan. 3. (U.S., 3.1.20.)
Koppers. Operating cupola and blast furnaces. 624—5, 832. Jan. 6 and 7. (Ger., 27.4.18, 28.3.19, 23.10.18.)
Linnmann. Cupola furnaces. 189. Jan. 4. (Ger., 22.4.18.)
Mathesius. Lead alloys. 485. Jan. 5. (Ger., 7.1.20.)

Mawer, Painton, and Parr. Annealing and hardening high and low carbon steels etc. 64. Jan. 3.

Schütz. Removing carbon from iron etc. 472. Jan. 5. (Ger., 11.1.18.)

COMPLETE SPECIFICATIONS ACCEPTED.

5400 (1917). British Thomson-Houston Co. (General Electric Co.). Metals and their manufacture. (155,851.) Jan. 12.

14,865 (1917). Head. Production of tungsten powder. (155,600.) Dec. 31.

15,772 (1919). Kissock. Manufacture of alloy steel. (131,877.) Jan. 12.

27,784 (1919). Akt. Ferrolegeringar. Production of manganese or its alloys. (135,186.) Jan. 12.

5532 (1920). Raworth (Dean). Soldering or coating aluminium or its alloys. (156,019.) Jan. 12.

9633 (1920). Alexander (Metal and Thermit Corp.). Formation of tungsten alloys. (155,739.) Dec. 31.

17,760 (1920). Goldberg. Electrolytically separating copper from nickel. (145,600.) Jan. 12.

24,343 (1920). Krupp A.-G. Separating slags containing iron from fuel residues. (150,333.) Jan. 12.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Reed. Electric furnace. 36,449. Dec. 30. (U.S., 27.3.20.)

Siemens-Schuckertwerke. Insulating-materials. 137, 985—6. Jan. 5 and 8. (Ger., 20.10.17, 14.12.17, 3.1.18.)

Urbasch. Electric batteries. 36,668. Dec. 31.

COMPLETE SPECIFICATIONS ACCEPTED.

21,187 (1919). Arosio. Insulating-material. (131,907.) Jan. 12.

25,505 (1919). Willard. Paste for storage battery plates. (155,944.) Jan. 12.

8471 (1920). Soc. l'Azote Franç. *See* VII.

17,760 (1920). Goldberg. *See* X.

24,854 (1920). Haglund. Electrolytic tanks with diaphragm cells. (151,260.) Jan. 12.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Byk Guldenwerke Chem. Fabr. 295. *See* XX.

Earp. Soap manufacture. 36,582. Dec. 31.

Fauth. Extraction of oil from oil seeds etc. 1022. Jan. 8. (Ger., 5.6.19.)

Granichstadten. Production of aroma of lard in artificial edible fats. 127. Jan. 3. (Austria, 18.6.15.)

Oelwerke Stern - Sonneborn. Recording automatic apparatus for testing oils and fats. 995. Jan. 8. (Ger., 24.2.19.)

Pech. Soap. 142. Jan. 3. (Fr., 9.1.20.)

Plauson and Vielle. Refining oils or fats. 689. Jan. 7.

Plauson and Vielle. 36,553. *See* II.

Schneider. Extracting oil from rape seed etc. 777. Jan. 7. (Ger., 25.1.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

17,880 (1919). Scott and Co., and Macgregor. Extraction of fat, wax, oil, gelatin, etc. (155,863.) Jan. 12.

18,538 (1919). Jackson (Nordiske Fabr. De-No-Fa). Producing soap powders with a high percentage of liquid fats and oils. (155,866.) Jan 12.

791 (1920). Green. Manufacture of margarine. (156,000.) Jan. 12.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Akt.-Ges. f. Aninlinfabr. Production of oil-colours, varnishes, etc. 283. Jan. 4. (Ger., 18.12.15.)

Burke, Jones, and Matthews. Manufacture of lithopone, zinc sulphide, and ammonia. 414. Jan. 5.

Chem. Fabr. Worms. Manufacture of printing and stamping colours. 154. Jan. 3. (Ger., 31.12.17.)

Chem. Fabr. Worms. 289 and 456. *See* III.

Chem. Fabr. Worms. Manufacture of artificial resins. 664. Jan. 6. (Ger., 31.3.19.)

Chem. Fabr. Worms. Manufacture of phenol condensation products. 804. Jan. 7. (Ger., 9.9.18.)

I.—GENERAL; PLANT; MACHINERY.

Boiler plants; Exact data on the performance of steam ——. Average figures for the performance of some different types of steam boilers. D. Brownlie. Engineering, 1920, 759—761, 797—799.

The results given were obtained both from 12-hr. tests and long check tests (one week), and as the results of the short period and long period tests were in excellent agreement they may be regarded as trustworthy, in spite of their disagreement with the figures usually put forward in text-books and by manufacturers. The figures given in the table are averaged from the results of the investigation of nearly 500 steam boiler plants in many different industries, and are calculated to a basis of:—Coal of 12,000 B.Th.U. and 10·5% ash at 40s. per ton; feed water temperature before economisers 110° F. (43° C.). Size of Lancashire boilers:—30 ft.×8 ft., with grates 6 ft.×3 ft. 2 in. Size of tubular boilers:—Rated evaporation 20,000 lb. of water per hr., heating surface about 5250 sq. ft., with grates 14 ft.×5 ft.—B. M. V.

	Cylindrical boilers ("Lancashire," etc.).		Water-tube boilers.		Small cylindrical boilers. Average.	Small vertical boilers. Average.

Distillation and rectification. L. Gay. Chim. et Ind., 1920, 4, 735—748. (*Cf.* J., 1920, 287 A, 701 A).

The facts established in previous communications (*loc. cit.*) for binary mixtures are applied to mixtures containing three constituents; the complex conditions etc. prevailing in the case of a ternary mixture are indicated graphically and algebraically, and certain rules concerning the minimum and maximum of heat compatible with the satisfactory working of a rectifying column are given.
—W. P. S.

Sulphuric acid concentrator and vacuum pump. O. Maas. J. Amer. Chem. Soc., 1920, 42, 2571—2574.

The liquid to be concentrated is placed in bulbs connected with a large cylindrical vessel filled with glass tubes, below which is placed reservoir. The apparatus is e Geissler pump and then sulphuric into the cylinder by an automatic con Chem. Soc., 1919, 41, 53), which has absorbing vapours, forcing the non-absor from the apparatus, and moistening the g The control then withdraws the acid into servoir, which improves the vacuum. The goes on repeatedly until the evaporation or centration is completed.—J. F. S.

Dialysis or extraction. Mann. *See* XXIII.

Patents.

Producing cold; Apparatus for ——. Soc. des Condenseurs Delas. E.P. 146,094, 5.6.20. Conv., 25.6.19.

The first stage of aspiration and re-compression of the vapour of water used as a refrigerant is effected by means of a rotating fluid-friction pump from which the vapour may pass direct to a condenser, or first through a steam ejector, the combined water vapour from the latter passing to the condenser. The live steam before passing to the ejector or the combined steam leaving the ejector may be used in a steam turbine which drives the fluid-friction pump. The latter may conveniently consist of a number of discs rotating between close-fitting (not rubbing) fixed spiral guides.—B. M. V.

Heat exchange apparatus [for gases]. H. Nielsen and F. D. Marshall. E.P. 154,308, 21.8.19.

A number of flat boxes connected by short pipes, carrying one gas, are arranged zig-zag fashion inside a casing which is provided with dampers to guide the other gas in a longer or shorter path, generally in an opposite direction to that of the first gas. The outer casing may also be provided with scrapers, operated from outside, to keep the outer surface of the boxes clean and with a hopper-like bottom from which any dust that may settle can be removed.—B. M. V.

Breaking, screening, washing, and assorting coke, pan breeze, furnace waste, and the like; Continuously acting apparatus for ——. E. J. A. Shaw and H. Blakeley. E.P. 154,376, 17.9.19.

A LONG rotating cylinder has a number of zones with perforations increasing in size progressively from the feed end; the finest material passing through the holes in the first zone drops straight to a hopper, but material passing through the second and subsequent zones drops into revolving drums concentric with and larger than the revolving cylinder, and having longitudinal troughs attached to their internal circumference and extending through their end walls. When the material collected in these troughs is raised to a suitable height it is subjected to washing by jets of water, so that the lighter material is washed over the ends of the troughs, while the heavier material remains in them and is carried round about another half revolution and is then discharged to a separate compartment.—B. M. V.

Grinding ores, minerals, stones, and the like; Machines for ——. J. R. Broadley. E.P. 154,434, 14.11.19.

A BALL, pebble, or tube mill is provided with two additional compartments beyond the grinding compartment. The pulp passes from the grinding compartment to the first auxiliary compartment through a perforated diaphragm, and is then lifted from the first auxiliary to the second auxiliary or classification compartment by means of a scoop, so that the pulp level is higher in the classification compartment than in the first auxiliary compartment. Slime is discharged from the classification compartment through a hollow trunnion, the internal opening of which is obstructed by a circular baffle of smaller diameter than the interior of the mill, thus forming a weir to retain sand. The sand is lifted by guides and returned direct from the classification compartment to the grinding compartment through an axial passage.—B. M. V.

Pulverising machine. C. E. Brainard. U.S.P. 1,360,364, 30.11.20. Appl., 8.1.20.

A CYLINDRICAL casing is divided transversely into two parts, which may be brought closer together by means of a separating ring the thickness of which can be reduced to compensate for wear of the grinding surfaces. The grinding surfaces converge radially and are removable, and enclose a floating crushing ring, the sides of which converge radially to correspond with the grinding surfaces. —W. F. F.

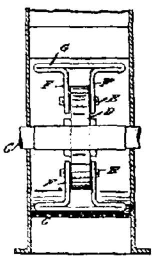
Crushing mill. T. J. Sturtevant, Assr. to Sturtevant Mill Co. U.S.P. (A) 1,360,465 and (B) 1,360,466, 30.11.20. Appl., 11.7.17 and 15.6.17.

(A) A CRUSHING mill comprises a crushing ring co-operating with revolving rollers mounted on a carrier. Pressure is transmitted from one roller to another by an equalising ring. (B) The carrier for the rollers is mounted on a cover which is hinged to the casing, and spring-pressed members are mounted on the casing to transmit pressure through the carrier to the rollers. These members and the carrier automatically separate when the cover is opened and engage when it is closed. —W. F. F.

[Grinding] mill; Combination —— and process of efficient operation thereof. P. C. Van Zandt, Assr. to Allis-Chalmers Manufacturing Co. U.S.P. 1,361,205, 7.12.20. Appl., 2.10.16.

MATERIAL is ground in the primary grinding chamber of a tube mill having two grinding chambers, and then transferred to the secondary grinding chamber. The relative volumetric capacities of the two chambers are then changed while the normal grinding level is maintained, and the grinding operation is continued.—W. F. F.

Reducing mill. E. B. Campbell, Assr. to Williams Patent Crusher and Pulverizer Co. U.S.P. 1,361,679, 7.12.20. Appl., 10.2.19.



REVOLVING hammers are pivoted at E to supports, D, carried by the rotating shaft, C. Each hammer consists of shanks, F, connected to a head, G, the thickness of which between the shanks is less than the thickness of the overhanging portions. The thicker parts effect a crushing action and the thinner part a slicing action.—W. F. F.

Ball mill. F. E. Marcy. U.S.P. 1,362,334, 14.12.20. Appl., 10.3.19.

A ROTARY grinding mill has one of its walls in the form of a number of rolled bars, spaced apart and forming a grate. The bars are welded together at their ends at points beyond the range of the grinding bodies within the chamber.—W. F. F.

Furnaces for heat-treating materials. W. A. Russell, and The Manchester Furnaces, Ltd. E.P. 154,521, 29.7.20.

THE furnace is somewhat similar to that described in E.P. 3339 of 1914 (J., 1914, 1014), but the inlets for flame consist of channels cut in the underside of the roof, alternating with one another on opposite sides; and the outlets for burnt gases are situated both at the mouth and back of the furnace. —B. M. V.

Furnaces [; Recuperative ——]. A. Smallwood. E.P. 154,866, 24.6.19.

THE furnace is of similar construction to that described in E.P. 125,224 (J., 1919, 372 A), but is adapted to heat materials that fill the chamber more or less completely. Combustion is arranged to take place before the gases enter the chamber, and to regulate the distribution of heat; the outlets, which are distributed along the side of the furnace, can be individually regulated.—B. M. V.

Oven. O. S. Sleeper, Assr. to Buffalo Foundry and Machine Co. U.S.P. 1,362,151, 14.12.20. Appl., 9.5.17.

A RETORT extends across the oven heating chamber and is provided with a number of longitudinal heating passages arranged in a vertical row and extending between inlet and outlet manifolds on opposite sides of the retort. Drying compartments, arranged in a vertical row, are disposed transversely to the heating passages and alternate with the latter. The drying compartments are permanently disconnected from the heating passages and are accessible through an opening in the side of the retort. A vertical baffle, extending above and below a heat delivery conduit from a furnace, is situated in the inlet manifold between the heat delivery conduit and the adjacent heating passages of the retort.—J. S. G. T.

Muffle-kiln; Continuous ——. H. Webster. U.S.P. 1,362,158, 14.12.20. Appl., 27.2.20.

A CONTINUOUS muffle-kiln comprises a series of heating chambers, separated by a solid wall and communicating each with its respective furnace arranged alongside the kiln. One or more of the chambers may be provided with muffles. Hot air flues extending through the roof of the muffle into the heating chamber open downwards through the

muffle floor and are connected with the main flue by longitudinal passages below the floor of the muffle.—J. S. G. T.

Heating furnace. G. J. Hagan and J. M. Hopwood. U.S.P. 1,362,296, 14.12.20. Appl., 14.10.18.

An annular chamber subtending an angle of less than 360° at its centre is provided with charging and discharging doors adjacent to its respective closed ends. Articles to be treated are placed upon an annular hearth movable in a counter direction to the flow of heat and products of combustion. Means for heating the furnace are disposed near the discharge end, and a connexion is made from the furnace to the stack near the charging end.
—J. S. G. T.

Furnace. G. J. Hagan. U.S.P. 1,362,297, 14.12.20. Appl., 14.5.20.

The bridge wall of a heating furnace is provided with a passage having its inlet communicating with a point near the bottom of the heating chamber, and its outlet so arranged that the products of combustion flow across it, thereby causing a flow of gases from the heating chamber through the passage.—J. S. G. T.

Kiln. C. D. Vezey and C. Mariner. U.S.P. 1,362,063, 14.12.20. Appl., 13.1.19.

An inclined shaft kiln is connected at the top with a return flue adjacent to the lower inclined wall of the kiln, the lower end of the return flue being connected with a draught flue. The connexion between the kiln and return flue is controlled by a damper, and controlled openings between the kiln and flue are provided at intervals along its length.
—W. F. F.

Centrifugal machine for [continuously] filtering or extracting liquids, semi-liquids, and other substances. J. McIntyre. E.P. 154,641, 30.5.19.

The apparatus consists of a central feed cylinder around which are arranged filtering cylinders. In addition to the high-speed rotation of the whole, the filtering cylinders rotate about their own axes at a lower speed. Vertical lines of holes are provided in the inner feed cylinder opposite the nearest points of the filtering cylinders, which are covered outside with cloths or other filtering medium and are provided internally with diametral baffles to catch the liquid which passes through into the inside of the cylinders and deflect it downwards to a collecting channel. The cake formed on the outside of the filtering cylinders is continuously flung off as it is carried round, as a result of the slower rotation of these cylinders around their axes. To regulate the feed the central cylinder is made double walled and the inner wall has a slight vertical movement, so that the feed holes can register or not.—B. M. V.

Clarifying liquids containing finely divided matter in suspension; Apparatus for ——. W. McD. Mackey. E.P. 154,766, 21.10.19.

A settling apparatus for, *e.g.*, sewage effluent, consists of a tank with vertical walls and sloping curved or flat floor and roof. The feed is at the bottom of the slope, the material having to pass under a curtain baffle and through the already settled matter, which acts as a filter for the fresh material; the outlet for clear liquid is at the top of the slope and for settled mud through a controlled spigot or pipe near the bottom of the slope. To make the liquid flow in parallel streams an obstruction may be placed at both the feed and outlet ends, consisting of plates either with a serrated edge or perforated.—B. M. V.

Presses; Filtering or dewatering —— *[for peat etc.].* A. Ten Bosch. E.P. 154,817, 19.1.20.

A press for such material as peat consists of a cylinder formed of a number of annular sections bolted together with distance pieces in between so that openings for expressed fluids are left at all the joints, the cross-section of the annular pieces being so shaped that the area for flow of expressed liquid increases rapidly outwards. The cylinder head and piston are so shaped (*e.g.*, hemispherical) that the parts which extend into the cylinder are of gradually decreasing diameter, their greatest diameter being a little less than that of the cylinder. The head and piston may also be built of sections, so as to leave annular openings communicating with their hollow interiors for exit of liquid. The cylinder may be enclosed in a steam jacket, in which case the annular openings in the cylinder will serve both for access of superheated steam to the charge before pressing and for discharge of liquid during pressing.—B. M. V.

Drying vegetable and like substances; Apparatus for ——. O. Zimmermann and H. Weyel. E.P. 154,998, 5.9.19.

The material to be dried is fed continuously through two narrow shafts, between and beside which are arranged chambers in which are means for heating the drying fluid. The walls of the shafts are preferably perforated, and the drying medium passes through transversely. The drying medium is passed when hottest over the wettest material in the top of the shafts. In the heating chambers the drying fluid (air) passes over steam coils or the like. Hot furnace gases may be used as drying medium, in which case the temperature may be regulated by addition of air to the circuit, an arrangement of perforated pipes and boxes being used to effect thorough mixing. The shafts may be divided about midway by flaps so that the drying of the material may be effected in two stages.—B. M. V.

Separating a volatile liquid from solution in a relatively non-volatile liquid; Apparatus for ——. W. K. Lewis and W. Green. E.P. 155,511, 31.1.19.

The apparatus is intended, more particularly, for the separation of a volatile solvent, *e.g.*, benzol or gasoline, from a non-volatile absorbent, *e.g.*, heavy hydrocarbon oil (*cf.* E.P. 152,374; J., 1920, 773 A). The mixture is fed to the top of a still, down which it passes in a zig-zag course over trays which are each heated by steam or other means, the clean heavy oil is removed from the bottom of the still, and the volatile solvent (containing some heavy oil) passes out at the top of the still. Live steam may be admitted to the bottom of the still and a vacuum may be maintained. The vapours from the still pass to a first condenser, where any entrained heavy oil is condensed, and then on through a reheater, to which a small quantity of dry air is admitted to improve the vacuum by preventing condensation. The mixture passes to a first vacuum pump and then to a second condenser for clean volatile solvent. Any vapour remaining uncondensed passes on to a second vacuum pump and a third condenser.—B. M. V.

Mixing materials; Machine for ——. T. J. Sturtevant, Assr. to Sturtevant Mill Co. U.S.P. 1,360,468, 30.11.20. Appl., 24.4.18.

Material is fed into a horizontal rotating drum having a set of inclined vanes attached to each end, the two sets being inclined in opposite directions to direct material towards the centre. A series of lifting buckets are provided around the periphery at the central zone, and the material is delivered by them on to a fixed inclined shoot, which deflects it towards one or other of the two ends of the drum.
—W. F. F.

Mixing apparatus for liquids; Automatic ——. O. Ritschel. G.P. 323,415, 24.10.18.

AN apparatus for mixing a small quantity of a liquid with a large amount of another different liquid while the latter is under pressure, consists of a container for the former liquid supporting and connected by two tubes with a pressure pipe through which the second liquid flows. One of the tubes allows free entrance of the liquid under pressure into the container, whilst through the other passes a capillary tube connecting the bottom of the container with the pressure pipe. Between the inlets of these tubes into the pressure pipe a regulating valve is arranged, whereby a pressure difference may be set up between the two connecting tubes so that the liquid under pressure is partly forced into the container on one side of the valve and, in its turn, forces an even, regulated stream of the liquid in the container through the capillary tube into the pressure pipe beyond the valve.—A. R. P.

Gases; Method of generating —— *and treating solutions therewith.* H. R. Hanley. U.S.P. 1,360,524, 30.11.20. Appl., 15.4.19.

GAS is passed into the liquid at a given level, and the partly spent gas is collected above the liquid surface and re-introduced into the liquid at a lower level.—W. F. F.

Condenser and method of condensation. N. H. Hiller. U.S.P. 1,360,748, 30.11.20. Appl., 9.7.15.

THE gas flows upwards through a series of superposed horizontal tubes connected in series, and is cooled and partly liquefied by a surrounding cooling medium. Liquefied gas is drawn off, and a proportion is passed through a conduit, having means for preventing a back flow of gas, to the lower part of the condenser.—W. F. F.

Filter. J. P. Probst. U.S.P. 1,361,493, 7.12.20. Appl., 17.3.19.

A VERTICAL cylindrical casing containing filtering material has its vertical walls perforated near the upper and lower ends. The two perforated zones are surrounded by annular chambers, and liquid is admitted to the filter through the lower chamber and discharged through the upper chamber. Contact of the filtering material with the perforations at the upper discharge end of the casing is prevented by a number of closely-spaced vertical strips within the casing over the perforated zone.
—W. F. F.

Evaporation; System of ——. W. L. De Baufre. U.S.P. 1,361,834, 14.12.20. Appl., 16.9.16.

AN evaporating chamber and a condensing chamber are connected by a number of ejectors which enable vapour to be withdrawn from the evaporator, compressed, and discharged under pressure into the condenser. The number of ejectors may be varied.
—A. J. H.

Evaporator and condenser. F. H. Schubert, Assr. to Brown-Ferrier Co. U.S.P. 1,361,910, 14.12.20. Appl., 28.3.19.

A COMBINED evaporator and condenser comprises a single vertical cylindrical casting open at the top, which projects into an annular closed chamber of larger diameter containing the liquid and forming part of the same casting. The lower part of the casting contains vertical condensing tubes fixed in tube-plates at both ends, and a collecting vessel is attached at the bottom.—W. F. F.

Evaporator. A. Vincik and F. Turek. G.P. 321,378, 6.3.18. Conv., 8.1.17.

THE apparatus consists of a series of heating chambers arranged side by side in a common vessel, each chamber being separated from the next and from the enclosing vessel by walls, so that the liquid passes over the whole heating surface of each chamber in succession.—A. R. P.

Interactions between gas and a liquid; Process of producing ——. P. W. Webster and V. K. Boynton, Assrs. to Perry and Webster, Inc. U.S.P. 1,361,940, 14.12.20. Appl., 20.11.19.

A GAS is passed into a liquid in such a finely-divided state as to avoid coalescence of its minute bubbles, thereby removing a portion of the liquid.—B. M.

Cooling liquids; Apparatus for ——. Maschinenbau A.-G. Balcke. G.P. 323,709, 19.5.18.

THE cooling surfaces are formed of elastic corrugated sheet metal, concave to the apparatus for spraying the salt solution, so that the salt is deposited on this surface in a bulky mass which, on account of the flexibility and nature of the surface, can readily be detached.—A. R. P.

Roasting in muffle-furnace; Process of ——. H. Frischer. G.P. 325,073, 18.8.17.

IN cases where material to be roasted cannot be introduced as a counter-current to the heating medium, it may be conveyed into the furnace through the gas or steam exhaust pipe. By this means it undergoes a preliminary heating, and caking in the furnace is prevented.—W. J. W.

Furnace. W. G. Zetsche. Reissue 15,009, 14.12.20, of U.S.P. 1,322,214, 18.11.19. Appl., 15.3.20.

SEE J., 1920, 1 A.

Refrigerating-gas and process of making the same. A. G. Crawford, Assr. to H. W. Seaman. Reissue 14,955, 12.10.20, of U.S.P. 1,325,666, 23.12.19. Appl., 29.7.20.

SEE J., 1920, 144 A.

Centrifugal separation. W. Mauss. U.S.P. 1,355,559, 12.10.20. Appl., 31.10.18.

SEE E.P. 133,448 of 1918; J., 1919, 886 A.

Evaporating or concentrating liquids; Apparatus for ——. E. Shaw. U.S.P. 1,355,702, 12.10.20. Appl., 5.5.19.

SEE E.P. 136,651 of 1918; J., 1920, 144 A.

Evaporators; Weir-overflow for ——. W. H. Ripley, Assr. to The Griscom-Russell Co. U.S.P. 1,361,905, 14.12.20. Appl., 17.5.17.

SEE E.P. 146,730 of 1919; J., 1920, 589 A.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; "Melting-point" of ——. G. Charpy and J. Durand. Comptes rend., 1920, **171**, 1358—1360.

IF finely powdered coal, moistened, moulded into a cylinder, and dried at 105° C., is slowly heated in a sealed tube under pressure of dry hydrogen, the cylinder first contracts and then gradually expands again and finally a second contraction characteristic of coking occurs. At the temperature corresponding to the maximum of the first contraction, the coal was noticed to soften and fill up the tube. Eight specimens of coal were examined, and of these a sample of anthracite did not "melt," another sample did not "melt" below 600° C., whilst the others "melted" at temperatures varying between 395° and 550° C. This "melting-point" is independent of the content of volatile matter, but is dependent on the state of oxidation, as the samples when first oxidised at 120° C. did not "melt" on heating as described above.—W. G.

Peat; Carbonisation of ——. Müller. J. Gasbeleucht., 1920, **63**, 817—820.

To be of use for carbonisation peat must not contain more than 25% of moisture or 5% of ash. Such peat yields 30% of gas, 5% of tar, and 0·25% of ammonia at a retort temperature of 1100° C. The drier the peat the less time is required for carbonisation, the period being usually 4—6 hrs. The coke obtained is equivalent to the best gas coke in calorific value, and the coke dust can be advantageously briquetted. The tar is lighter than coal tar and is separated from water with difficulty. It is more valuable than coal tar, giving a higher yield of oils. Large quantities of very dilute ammonia liquor are obtained, the total content of ammonia being large. The gas is heavier than coal gas, but may be purified in the same manner. The carbon dioxide content of the gas is high, being usually about 12%. The calorific value is not less than 4000 cals. In the tests described 6 horizontal retorts were filled with peat and 3 with coal, the coke from 2 of the latter serving for heating the retorts.—W. P.

Lignite and wood; Carbonisation of ——. R. Geipert. J. Gasbeleucht., 1920, **63**, 792—794. (*Cf.* J., 1920, 180 A.)

The costs and efficiencies of lignite and wood carbonisation processes are compared with those of the carbonisation of coal. Lignite and wood can only be regarded as very poor substitutes for gas coal. The coke produced is poor in quality, and in any case is insufficient in quantity even for heating the retorts. The ammonia liquor from lignite is too dilute to be economically treated for recovery of ammonia.—W. P.

Coke-oven gases; Composition of some ——. P. Lebeau and A. Damiens. Comptes rend., 1920, **171**, 1385—1386.

Four specimens of coke-oven gases were analysed and the following ranges in composition were found:—O_2, 0—0·69%; CO, 6·41—7·39%; H_2, 33·30—44·00%; N_2, 8·06—20·37%; CO_2, 2·79—4·35%; CH_4, 23·57—41·34%; C_2H_6, 0·45—1·64%; C_3H_8, 0·02—0·22%; acetylene hydrocarbons 0·06—0·09%; C_2H_4, 1·09—3·68%; propylene and homologues 0·08—0·11%; not determined (moisture, benzene, etc.) 0·36—0·56%. The approximate temperature of the furnaces at the time of taking the samples was 950°—1000° C. These gases differ in composition from coal gas in that they contain less hydrogen, much more nitrogen, and little or no benzene.—W. G.

Inflammable gases and vapours; Effect of oxygen on the limits of inflammability of ——. E. Terres. J. Gasbeleucht., 1920, **63**, 785—792, 805—811, 820—825, 836—840.

The limits of inflammability of carbon monoxide, hydrogen, water-gas, coal gas, methane, ethane, acetylene, ethylene, benzine, and benzene have been determined in air, in pure oxygen, and in atmospheres containing more oxygen than air. In all cases the lower limit differed only slightly in air and in oxygen, but the upper limit was always very much higher in pure oxygen. (*Cf.* J.C.S., Feb.)
—W. P.

Hydrogen and inert gas [helium]; Inflammability of jets of ——. P. G. Ledig. J. Ind. Eng. Chem., 1920, **12**, 1098—1100.

Under favourable conditions a jet of helium containing more than 14% of hydrogen can be ignited in air, but 18—20% of hydrogen may be mixed with helium without producing a mixture which will burn with a persistent flame when issuing from an orifice under the conditions prevailing in balloon practice. More than 20% of hydrogen in a hydrogen-helium mixture cannot be used without sacrificing safety from fire.—W. P. S.

Petroleum refining vapour systems; Prevention of corrosion in ——. R. R. Mathews and P. A. Crosby. Chem. and Met. Eng., 1920, **23**, 1122—1123.

To prevent corrosion of the fractionating system by hydrochloric acid generated in the distillation of petroleum containing brine, anhydrous ammonia is added as a neutralising agent. The amount is carefully regulated so as to ensure that the water from the last dephlegmator gives an alkaline reaction. The average amount of iron dissolved per day was 5·18 kg. without, and 2·18 kg. with, ammonia treatment. In addition, the period before tubes had to be replaced in the tubular condenser was extended from 100 to 280 days. Deposits of ammonium chloride must be periodically removed. The substitution of soda ash for ammonia proved unsatisfactory, but aqueous ammonia may be used instead of anhydrous ammonia.—W. J. W.

Explosion limits. Jorissen. *See* VII.

Gas analysis. Tour. *See* XXIII.

Patents.

Peat, brown coal or the like; Method of treating —— *and apparatus therefor.* T. A. Goskar and G. E. Thomas. E.P. 155,012, 8.9.19.

Peat is mixed with a gritty material such as powdered coal and then compressed, whereby the cells of the peat are broken and the water content liberated. The peat may then be distilled to recover oils etc., and the resulting coke may be crushed and used as the gritty material.—W. F. F.

Coke oven; Regenerative ——. L. Wilputte, Assr. to A. A. Wilputte. U.S.P. (A) 1,360,609 and (B) 1,360,610, 30.11.20. Appl., 18.9 and 30.9.18.

(A) A series of parallel horizontal coking chambers are heated by vertical flues in the dividing walls. The walls are connected in pairs at their upper ends and gas is supplied alternately to each of the flues of each pair at the bottom. Each flue is connected at the bottom with a separate regenerator. (B) A number of regenerators are arranged side by side with a longitudinal brickwork flue of square cross section running below them, and connected with each by a vertical port. The flue contains a removable metal pipe of circular cross section having openings which register with the ports. The pipe is provided with projecting cam surfaces which occupy the corner of the brickwork flue when the pipe is being inserted, but which engage with the bottom of the flue and lift the pipe against the top of the flue when the pipe is rotated.—W. F. F.

[Carbonising] oven with regenerator. C. Berthelot. U.S.P. 1,361,671, 7.12.20. Appl., 15.8.19.

An oven is composed of adjacent carbonising chambers, heated by vertical flues between them. There is a regenerator below each chamber, and a single longitudinal horizontal flue above the vertical flues, and means are provided for connecting one regenerator with one half of the vertical flues between two chambers, and these flues with the longitudinal flue. Means are also provided for connecting the same longitudinal flue with the other half of the vertical flues, and these with the other regenerator below the adjacent chamber.
—W. F. F.

Water-gas producers. F. G. C. Rincker. E.P. 139,451, 16.9.19. Conv., 24.2.19.

A pair of generators working reversibly and connected together are used for the gasification of coal, lignite, peat, wood, etc. Each has an exhaust connexion to the air. In one water-gas is gener-

ated from coke by alternately blowing with air and steam. During the air blast the gas is passed into the atmosphere, but during the steam blast the hot water-gas is passed through the other generator in which its heat effects the distillation of a fresh charge of fuel. When the latter is coked the two generators are reversed. The heat usually lost in the incandescent coke is thus saved.—C. I.

Water-gas; Generator for producing ——. E. Dolensky, Assr. to The Chemical Foundation, Inc. U.S.P. 1,362,089, 14.12.20. Appl., 11.1.16.

A WATER-GAS generator is connected with a purifier having a water receptacle at the bottom partly open to the atmosphere. A compressed air pipe is connected with the gas pipe between the generator and the purifier, but air is prevented from passing directly into the purifier by a relief branch from the air pipe dipping into the part of the water receptacle open to the atmosphere.—C. I.

Gas producer. T. Clouston. U.S.P. 1,362,559, 14.12.20. Appl., 28.8.19.

FINELY-DIVIDED carbonaceous fuel, hot air, and steam are injected axially into one end of a mixing chamber which extends through the gas generating chamber from one end nearly to the other, the inner end being open. The gas generated passes out through a number of short transverse slots in the generating chamber to the delivery pipe. The generating chamber is enclosed in a jacket containing refractory material.—W. F. F.

Ethylene; Extraction of —— from gaseous mixtures [and its recovery as alcohol]. W. Traube. E.P. 147,543, 4.6.20. Conv., 14.7.19.

GAS containing ethylene, *e.g.*, dry coke oven gas, freed from benzene, is sprayed with 90—100% chlorosulphonic acid with cooling. The resulting liquid containing 90—100% of the ethyl ester of the chlorosulphonic acid is decomposed with its own volume of water with formation of alcohol and hydrochloric and sulphuric acids.—C. I.

Gas; Method and apparatus for cooling ——. A. W. Warner, Assr. to The American Gas Co. of New Jersey. U.S.P. 1,362,207, 4.12.20. Appl., 2.11.18.

GAS from each retort of a series passes through a shower of cooling liquid and into a standpipe which also contains cooling liquid. The gas from all the standpipes passes into a common cooling main where it is further cooled by a shower of cooling liquid.—W. F. F.

Paraffin wax; Treatment of —— for the production of oxygenated compounds [fatty acids etc.]. A. Schmidt. E.P. 142,507, 30.4.20. Conv., 15.1.16.

AIR or oxygen is blown through paraffin wax at 100°—120° C. until the colour changes to a deep yellow, *i.e.*, for about 50 hrs. The oxygenated compounds such as fatty acids, oleic acids, and small quantities of aldehydes, alcohols, and the like, are separated from undecomposed paraffin wax, *e.g.*, by distillation. The presence of a catalyst, such as mercury oxide or previously treated wax, increases the rapidity of the reaction. —L. A. C.

Gasoline; Manufacture of ——. F. E. Wellman. U.S.P. 1,362,160, 14.12.20. Appl., 24.6.19.

PLANT for the manufacture of gasoline comprises a cracking chamber, a discharge pipe provided with controlling valve, a supplemental elevated vapour chamber from which heavy liquid fractions drain back into the cracking chamber, and a condenser connected by a pipe with an elevated part of the vapour chamber. The capacity of the condenser is large relatively to the delivery capacity of the connecting pipe at high initial pressure, and the capacity of the pipe is small relative to that of the vapour chamber, so that pressure is maintained in the latter and the vapours expand on passing into the condenser.—J. S. G. T.

Lubricating oil; Production of —— from lignite producer-gas tar oil. Badische Anilin und Soda-Fabr. G.P. 310,075, 15.4.17.

THE oil obtained by distilling the dehydrated tar is freed from paraffin and heated under pressure to 250°—400° C. Low-boiling constituents are separated from the product by distillation, and are suitable for use in Diesel engines.—L. A. C.

Lubricating oils; Production of —— from coal tar oils. H. W. Klever. G.P. (A) 310,634, 22.5.18 (Addn. to 301,774–7; J., 1920, 327 A, 441 A), and (B) 310,713, 22.5.18.

(A) A LARGER quantity of oil is allowed to distil during the heating process, and the distillate is returned to the bulk of the oil when the heating is complete. (B) The oil is heated in the presence of a solvent, *e.g.*, oil from naphthalene fractions which is separated afterwards by distillation. —L. A. C.

Lubricating greases; Manufacture of ——. Rütgerswerke A.-G. G.P. 326,271, 23.2.18.

LUBRICATING oils are heated with tar acids, or tar-oil fractions of high acidity, to which lime has been added.—W. J. W.

Sulpho-acids and alkylsulphuric acids from acid resins [from refining mineral oils and tar oils]. Process for obtaining the salts of ——. Sudfeldt und Co. E.P. 148,579, 10.7.20. Conv., 14.3.19

THE acid resin obtained, *e.g.*, from the refining of oil with fuming sulphuric acid, is dissolved or emulsified in water or an alkaline solution and subjected to fractional precipitation by the addition of sodium or calcium chloride. Sufficient salt is first added to precipitate sulphones and hydrocarbons together with only a small portion of the sulphonic acids, and, after separation of the precipitate, the bulk of the sulphonic acids is thrown down by the further addition of salt. The salts of the alkylsulphuric acids and sulphonic acids so precipitated may be purified by solution in water and further fractional precipitation or by treatment with alcohol or with oxidising agents, and may be used as a substitute for asphalt.—L. A. C.

Powdered fuel; Means for feeding —— to furnaces. L. C. Harvey. E.P. 155,389, 24.9.19.

Gas making retorts, producers, or the like; Charging of inclined or vertical ——. R. and J. Dempster, Ltd., and G. F. H. Beard. E.P. 155,167, 15.4.20.

Coke or other material resulting from distillation in vertical retorts; Retaining device for ——. *Apparatus for discharging material at the base of vertical continuous distillation retorts.* J. Pieters. E.P. 155,750—1, 27.2.20.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Coal; Low-temperature distillation of ——. N. Young. E.P. 134,529, 15.10.19. Conv., 1.11.18.

COAL is continuously distilled at 500°—550° C. in an inclined rotating retort, which is sealed at both ends against the admission of air. The retort is

heated by an external furnace, or by passing hot or superheated producer gas through the charge, or these methods may be combined. The charge is disintegrated during rotation by means of iron crushing balls within the retort. In a modification, two concentric drums are used, both being charged with coal. The coal in the outer drum is partly or completely gasified by admitting air, and the coal in the inner drum is distilled.—W. F. F.

Mercury vapour lamp; Quartz ——. H. George. U.S.P. 1,361,710, 7.12.20. Appl., 11.4.19.

A lamp, operated by alternating current, comprises a quartz tube connected at each end by a thick-walled, narrow bore tube with a spherical mercury container having an inner spherical bulb communicating with it by a small hole on the side opposite the quartz tube. The leading wires pass into the inner spherical chamber. The quartz tube is filled with an inert gas under pressure which acts as a conductor for the current until enough of the mercury is vaporised.—B. V. S.

Charcoal; Process of producing decolorising ——. R. von Ostrejko, Assr. to Chemical Foundation, Inc. U.S.P. 1,362,064, 14.12.20. Appl., 13.12.16.

See E.P. 106,089 of 1917; J., 1918, 177 A.

III.—TAR AND TAR PRODUCTS.

Lepidine and related bases; Preparation of ——. L. A. Mikeska. J. Amer. Chem. Soc., 1920, 42, 2396—2397.

A fair yield of pure lepidine (4-methylquinoline) may be obtained by the following process. A mixture of 300 g. of acetone and 300 g. of 40% formaldehyde is cooled in ice and saturated with hydrogen chloride, this process being repeated the next day. On the third day the product is added slowly to a cooled mixture of 300 g. of aniline and 600 g. of hydrochloric acid (sp. gr. 1·2) and the mixture heated on a water-bath under a condenser for 3 hrs. After cooling, the mixture is extracted with ether, the extract is dried, the ether distilled off, and the residue distilled under reduced pressure. The distillate is heated on a water-bath for ½ hr. with its own weight of acetic anhydride and then poured into water and filtered. The filtrate is neutralised and the lepidine recovered by extraction. If the aniline is replaced by *p*-toluidine, *p*-tolulepidine (4.6-dimethylquinoline) is obtained and if *p*-phenetidine is used 6-ethoxy-4-methylquinoline is the product.—W. G.

IV.—COLOURING MATTERS AND DYES.

Isocyanine dyes from lepidine and its homologues. E. Q. Adams and H. L. Haller. J. Amer. Chem. Soc., 1920, 42, 2389—2391.

The quaternary additive compounds of pure lepidine or its homologues when treated with alcoholic alkalis in hot, concentrated solution give dyes of the isocyanine type, similar to, but not identical with, those given by the corresponding derivatives of quinaldine. Isocyanines of this type have been prepared from lepidine methiodide and ethiodide and from tolulepidine methiodide, ethiodide, and methonitrate. The isocyanine from lepidine ethiodide is probably isomeric with that from quinaldine ethiodide and resembles it in photosensitising properties. (*Cf.* J.C.S., Jan.)—W. G.

Photosensitising dyes; Synthesis of ——. *II. Dicyanine A.* L. A. Mikeska, H. L. Haller, and E. Q. Adams. J. Amer. Chem. Soc., 1920, 42, 2392—2394.

When *p*-phenetidine is condensed with paraldehyde and acetone, the product heated with acetic anhydride and then diazotised, and the diazo compound destroyed by heating the solution on a water-bath, 6-ethoxy-2.4-dimethylquinoline, b.p. 314°—316° C. is obtained. If the ethiodide of this base is converted into the ethonitrate and then treated with sodium ethoxide in absolute alcohol, air being bubbled through the mixture, grass-green crystals of Dicyanine A nitrate are obtained, whilst if the ethiodide is treated directly with sodium methoxide in methyl alcohol, Dicyanine A iodide is obtained.—W. G.

Kryptocyanines. A new series of photosensitising dyes. E. Q. Adams and H. L. Haller. J. Amer. Chem. Soc., 1920, 42, 2661—2663.

When lepidine ethiodide is dissolved in boiling alcohol and slowly treated with a solution of sodium ethoxide and formalin, air being excluded, a purple-black dye of a new class designated "Kryptocyanines," and specified as "K III.," is formed. It has an absorption-maximum near 7000 A. units and a sensitisation-maximum near 7400 A. (*Cf.* J.C.S., Feb.)—J. C. W.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wood and wood pulp infection and decay. O. Kress. Pulp and Paper Mag., 1920, 18, 1225—1229.

In a study of the various moulds and wood-destroying fungi commonly found on pulp or pulp wood, more than seventy different kinds of organisms were isolated. The chemical changes involved in decay of the four chief pulp woods (spruce, hemlock, balsam, and aspen) are considered, and complete analyses of sound and infected woods are reported. The progress of decay is indicated most distinctly by decrease in the content of α- or stable cellulose and increase in the content of β- or unstable cellulose. Papers made under similar conditions from infected pulps, or pulps prepared from woods in varying degrees of decay, show decreasing strength

tests compared with paper made from sound pulps, especially in those tests which measure the tenacity and the brittleness of the pulp. If pulp is prepared from infected wood it shows a remarkable decrease in fibre length, it is much darker in colour, and it produces a paper with a decidedly reduced strength. It will also require more sizing than sound pulp or pulp produced from sound wood.

Cellulose; Conversion of —— into glucose [dextrose]. Constitution of polysaccharides. II. J. C. Irvine and C. W. Soutar. Chem. Soc. Trans., 1920, 117, 1489—1500.

In previous researches on the hydrolysis of cellulose the yields of dextrose which have been claimed have not been based on the quantity of the sugar or of a characteristic derivative actually isolated, and the statements made are unreliable. With the object of ascertaining whether cellulose is really essentially a polyglucose anhydride, yielding the theoretical quantity of dextrose on hydrolysis, a normal cotton cellulose was hydrolysed by means of acetic anhydride and sulphuric acid. The product was poured into water and the precipitate of polysaccharide acetates simultaneously hydrolysed and converted into methylglucoside by heating in an autoclave with 0·5% methyl-alcoholic hydrogen chloride. About 25% of the material resisted hydrolysis by this method and was hydrolysed with dilute aqueous hydrochloric acid and the product again brought into reaction with acid methyl alcohol. The water-soluble products first obtained were also converted into methylglucoside, and in this way a total yield of pure crystalline methylglucoside was obtained in three distinct stages of progressively increasing difficulty, amounting to 85% of the quantity theoretically possible if cellulose consisted entirely of dextrose residues. Evidence of the non-uniformity of the dextrose linkages in cellulose is thus afforded by the variation in the ease with which the dextrose residues are eliminated from the polysaccharide by acid hydrolysis. The proportion of the cellulose molecule which is most resistant to hydrolysis agrees closely with that corresponding with the maximum yield of cellobiose octa-acetate obtained from cellulose, and this disaccharide apparently represents the most resistant portion of the cellulose molecule.—G. F. M.

Cellulose; Decomposition of —— by aërobic bacteria. J. Groenewege. Med. Geneesk. Lab. Weltevreden, 1920, 163—269.

There are two views as to the decomposition of cellulose in nature: one that it is anaërobic and brought about by organisms which are not positively determined; the other that it is aërobic and brought about by two groups of organisms, one group decomposing cellulose directly, the other group being denitrifying organisms. Extensive experiments were carried out from the second point of view, all the cultures being made aërobically. A septic tank liquid and earth were used as the sources of the organisms. The culture medium consisted of tap water to which were added 2% of filter paper, 0·25% of potassium nitrate, and 0·05% of dipotassium phosphate. When this medium was inoculated with either of the substances mentioned and incubated at 37° C. gas was given off, the nitrate was reduced to nitrite and to nitric oxide, and the paper was reduced to a pulp; if at this stage the solution was poured off from the pulp and fresh medium (without filter paper) added, reduction of nitrate again took place, and the pulp was gradually dissolved. The organisms in these cultures were sub-cultivated on agar plates and pure cultures obtained. These were found to fall into three groups: those which effected denitrification but did not attack cellulose; those which did not denitrify but attacked cellulose; and those which did neither. The first group contained *Bacillus viscosus* and *B. opalescens*, and the second group *B. cellaresolvens* α, β, and γ. Cultivations of each member of one group with each member of the other group were made and full details of the results are given. It is concluded that the three varieties of *B. cellaresolvens* attack cellulose, and that the decomposition products serve as food for the denitrifying organisms, *B. opalescens* and *B. viscosus*, the complete process being thus a symbiotic one. The end products of cellulose decomposition are acetic, butyric, and lactic acids, which are oxidised to carbon dioxide and water by the denitrifying organisms. It is suggested that the decomposition of the cellulose may be brought about by an enzyme, cellulase.—J. H. J.

Paper; Perishing of —— in Indian libraries. J. J. Sudborough and M. M. Mehta. J. Indian Inst. Sci., 1920, 3, 119—226.

Paper in Indian libraries, especially in Plains stations such as Calcutta, Madras, and Bombay, will not withstand the climate and perishes very rapidly. This is more noticeable with papers prepared from wood pulp, and especially those in which the fibres have been weakened because of the different treatments to which they have been subjected. The addition of arsenic trisulphide as a preservative is useless, because, although it preserves paper from the ravages of insects, it accelerates the perishing of the fibres. Paper used for books which have to be preserved in stations like those of the Indian Plains should be prepared only from strong rag fibres, should have no distinct acidity, and should withstand a severe test in the folding machine. Its contents of rosin and filling materials should be below certain fixed values. The rag fibres should not be weakened by prolonged digestion with alkali or by over-bleaching, and care should be taken to remove the last traces of bleaching agent and of free acid. (*Cf.* J., 1898, 595.)
—J. C. K.

Gas-stopping linings for use in aircraft, and media for fixing the same and processes for manufacturing said linings. V. C. Richmond. E.P. 154,942, 20.12.16 and 20.7.17.

A film suitable for ballonet linings consists of a central gas-stopping layer containing gelatin or glue as its chief constituent as regards low permeability to hydrogen, a protective layer containing nitrocellulose, and an attachment layer containing rubber. To prepare the film a mixture of nitrocellulose jelly 200 lb., butyl acetate 40 galls., naphtha 40 galls., and castor oil (to confer flexibility) 8 galls., is sprayed on to a highly-polished surface at 60°—100° F. (16°—38° C.), preferably at 75° F. (24° C.), and allowed to dry. A mixture of gelatin 5½ lb., water 5½ galls., and glycerin 45 oz., is applied as a second layer, and is allowed to dry. The third layer is formed by spraying on a mixture of 32 oz. of a solution containing nitrocellulose jelly 200 lb., butyl acetate 40 galls., naphtha 36 galls., which mixture is diluted to twice its bulk with butyl acetate; 13 oz. of a rubber solution composed of rubber 8·5 pts. and naphtha 91·5 pts. by weight; 6 oz. of naphtha, and 1 oz. of castor oil. After the third layer is dry, the composite film is peeled off, and may be suitably fixed to a fabric by means of a rubber solution. The film has a permeability for hydrogen of approx. ½ l. per sq. m. per 24 hr. both before and after severe crumpling, and its weight is approx. 70 g. per sq. m. A composite film may be made from separate films each containing rubber and dinitrocellulose by use of an adhesive solution prepared from rubber 5·5 pts., naphtha 83·5 pts., and amyl acetate 11 pts.

Vool washing and like machinery. T. W. Hawkins. E.P. 155,416, 21.10.19.

'HE floor of the washing bowl is sloped and along he lowest part is a mechanical scraper or con-eyor, whereby the accumulated sludge is led to a ank situated at one end of the bowl. A screw onveyor is so arranged and works at such a speed s to transfer the sludge, but not the scouring quor, in this receptacle to another tank where it ıay be suitably treated.—A. J. H.

Dyeing vats. A. A. Vallaeys. E.P. 140,764, 16.3.20. Conv., 21.3.19.

'HE dyeing vat, the gearing which is fixed inde-endent of the vat, and a hood through which apours are withdrawn are arranged to form a losed system. The vat is divided by a perforated ertical partition near one of the walls, and the maller division is further divided by a non-erforated plate extending to within 15 cm. of the ottom of the vat. The dyestuff is introduced into he smaller compartment. Inspection of the vat nterior is possible by means of two large flap doors. 'he hood is maintained under slightly reduced ressure, contains a steam-heated coil to prevent ondensation of water, and is connected with the emainder of the system by means of a flap valve. —A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

'itrogen oxides; Determination of —— in nitrogen fixation processes. G. B. Taylor. Chem. and Met. Eng., 1920, 23, 1112.

. 2-l. bottle is filled with the gas under examina-ion and oxygen is added, if not already present in sufficient excess, to convert nitric oxide into per-oxide. The temperature and pressure of the gas are determined, and 25—50 c.c. of 1·5% hydrogen peroxide solution, prepared by diluting commercial 3% solution with an equal volume of water and neutralising with $N/10$ sodium hydroxide, is then added and shaken with the gas till the red colour disappears. After standing for 5 mins. the mixture is again shaken, and finally titrated with $N/10$ sodium hydroxide, with methyl orange as indicator. The percentage of NO is found from

$$224a/[v\times(b-p)\times273/760(273+t)],$$

a being the c.c. of alkali, v the volume of the bottle, p the pressure in the bottle, b the barometric pressure, and t the temperature of the gas. This formula is accurate for concentrations up to 3% NO. If the temperature of the gas is considerably above room temperature a measured volume of water may be added after the agitation with hydrogen peroxide, and the formula then becomes

$$224a/[(v-v')(b-p-w)273/760(273+t)+2\cdot24a],$$

where w=vapour pressure of water at $t°$, and v'= volume of peroxide solution plus water.—W. J. W.

Phosphoric acid; Production of —— by smelting phosphate rock in a fuel-fed furnace. W. H. Waggaman and T. B. Turley. Chem. and Met. Eng., 1920, 23, 1057—1063.

For the continuation of their previous large-scale experiments (J., 1920, 595 A), the authors constructed a furnace of semi-commercial size with auxiliary equipment for burning the combustible gases and collecting the phosphoric acid evolved. The plant comprised an oil-fed furnace capable of dealing with a 700 lb. charge, a dust catcher for the gases and fumes, stoves for burning the combustible gases, a Cottrell precipitator, and an air preheater. The material was in the form of egg-shaped and pillow-shaped briquettes. The results of the last two of six runs were recorded. In the first case over 52% of the phosphoric acid was evolved during fusion of the charge, at the rate of about 80·5 lb. P_2O_5 per hr., with a fuel consumption of 9½ galls. of oil, or 8·5 lb. P_2O_5 per gall. The slag obtained after the furnace had cooled contained 7·99—13·63% P_2O_5; the volatilisation was therefore 38—65·3% of the original amount in the charge. The run was not completed. In the second case the yield per gall. of fuel during the last 2 hrs. at the maximum temperature (1500°—1600° C.), was 5·56 lb. P_2O_5. The phosphoric acid in the slag was 0·77%, indicating a volatilisation of 97% of the original acid. The cost per ton of phosphoric acid, assuming a 90% yield by this process, was estimated to be $49·83 as compared with $81·25 when produced as acid phosphate (superphosphate) by the sulphuric acid process.—W. J. W.

Electrolytic diaphragm cells [for production of alkali and chlorine]. H. K. Moore. Amer. Inst. Chem. Eng., June, 1920. Chem. and Met. Eng., 1920, 23, 1011—1015, 1072—1074, 1125—1128.

In the unsubmerged diaphragm cell filled with brine the gradual increase in strength of the caustic soda tends to cause its diffusion into the anode compartment, with consequent loss of carbon from the anodes caused by the action of nascent oxygen produced by the formation and subsequent decomposition of sodium hypochlorite. Diffusion may be checked by keeping the brine at a higher level in the anode compartment, by the addition of water to the caustic soda to lower the temperature and to decrease the concentration, or by causing the caustic soda to flow away as fast as it is formed. Anodes of Acheson graphite are less readily attacked than those of gas carbon. As a measure of the efficiency of cells the rate of flow which represents the volume or weight of caustic solution per ampère-hour per sq. ft. of diaphragm has been adopted. With a high rate of flow current efficiency is low on account of

the large amount of chlorine dissolved in the brine, and as the rate of flow diminishes the current efficiency rises to a maximum and then diminishes. In running a cell plant with the aid of rate of flow charts it is necessary to regulate each cell individually. The voltage of cells rises when the diaphragms are not washed periodically and is also higher with unpurified than with purified brine; a washed diaphragm is superior to a new diaphragm. Increase of temperature of the brine lowers the cell voltage and increases the rate of flow. Decrease of chlorate in the caustic liquor with increase of temperature is probably attributable to the increased activity of nascent hydrogen at the cathode. High efficiency in a cell is sometimes due to a temporary lag in the running-off of the caustic liquor. Small quantities of sodium sulphate in the brine have a deteriorating effect, the carbons being attacked to a greater extent and hence the amount of carbon dioxide in the chlorine increased. The presence of sulphate further increases the amount of chlorate, which constitutes a risk during evaporation of the caustic solution. Numerous graphs and tables of the results are given.—W. J. W.

Sodium permanganate; Electrolytic preparation of ——. C. O. Henke and O. W. Brown. J. Phys. Chem., 1920, 24, 608—616.

THE effect of temperature, current density, and concentration of the alkali upon the production of sodium permanganate was studied, using an anode containing 92% of manganese, the impurities being for the most part silicon, iron, and carbon. The anode was prepared by reducing pyrolusite with coke in an electric arc furnace. The cathode was a perforated platinum plate, and the electrolyte a solution of caustic soda containing 10 g. NaOH per litre. The presence of a diaphragm is not necessary if an excess of calcium hydroxide is added to the electrolyte. This addition increases the current efficiency from about 16% to 33%. The calcium hydroxide appears to form a film over the cathode, which acts as a diaphragm. The highest current efficiency was obtained with a current density of about 13 amps. per sq. dm. With a low temperature the current efficiency is increased, *i.e.*, from 3·1% at 60° and 20·1% at 40° to 38·6% at 8° C. As in the case of lead (J., 1920, 603 A), when used as an anode in sodium hydroxide solutions, the discharge potential is higher when the manganese goes into solution with a higher valence, *i.e.*, as permanganate.—J. C. K.

Phosphates; Volatilisation loss of phosphorus during evaporations of —— with sulphuric acid or fusions with pyrosulphate. W. F. Hillebrand and G. E. F. Lundell. J. Amer. Chem. Soc., 1920, 42, 2609—2615.

No volatilisation losses of phosphorus occur during evaporation of sulphuric acid solutions of phosphates, provided the evaporation is carried on at 150° C. and stopped when fumes appear. Volatilisation losses of phosphorus from sulphuric acid solutions of phosphates may occur during evaporation to complete expulsion of sulphuric acid, during evaporation at high temperatures, such as 200°—260° C., and by unduly prolonged evaporation above 150° C. Evaporations involving only a drop or two of sulphuric acid, such as apply in silica treatments, do not cause measurable losses. Fusion with pyrosulphate in covered crucibles and at dull red heat results in appreciable losses in the case of secondary phosphates, and may result in slight losses in the case of basic phophates. Orthophosphoric acid and primary and secondary orthophosphates suffer conversion to pyro- and metaphosphoric acid or phosphates when evaporated to dryness with sulphuric acid or fused with pyrosulphate; such "converted" compounds must be subjected to reconversion treatments before precipitation with molybdic acid o magnesia mixture.—J. F. S.

Adsorption by precipitates [of hydrous aluminium oxide]. H. B. Weiser and E. B. Middleton J. Phys. Chem., 1920, 24, 630—663.

HYDROUS aluminium oxide adsorbs ions relatively strongly, the adsorption values being approximately one-third larger than those for hydrous ferric oxide The results obtained for aluminium oxide confirm those obtained previously, viz., that the amount of various ions carried down by the precipitated colloid are not even approximately equivalent, contrary to Freundlich's assumption. The order o adsorption as estimated by direct analysis is not th same as the one deduced from the precipitation values of electrolytes, because the latter do no depend exclusively on the valence and adsorbability of the precipitating ions.—J. C. K.

Hydrogen peroxide; Properties of pure ——. O Maass and W. H. Hatcher. J. Amer. Chem Soc., 1920, 42, 2548—2569.

PURE hydrogen peroxide is prepared as follows 3% peroxide obtained from barium peroxide is concentrated to 30% by means of a sulphuric acid concentrator (see p. 69 A). It is then distilled at low pressure to remove non-volatile impurities, concentrated to 90% by the sulphuric acid concentrator and pure hydrogen peroxide then separated by fractional freezing. In this way a 50% yield of 100% hydrogen peroxide is obtained. Pure hydrogen peroxide is not very soluble in ether; it dissolve many salts and attacks glass. When sodium i added it explodes violently. It whitens but doe not permanently destroy living skin. It is quit stable if kept at 0° C. It has the following physical properties: Freezing point, $-1·70°$ C. sp. gr. of liquid at 0° C., 1·4633; mean coefficient c expansion, $-10°$ to $+20°$ C., 0·00107; sp. gr. o solid, 1·644; sp. heat of liquid, 0·579; latent hea of fusion, 74 cals.; specific heat of solid, 0·470 viscosity at 0° C., 0·0128 (Ostwald); $n_D^{22}=1·4139$ (*Cf.* J.C.S., Feb.)—J. F. S.

Hydrogen peroxide; Properties of pure ——. O Maass and O. W. Herzberg. J. Amer. Chem Soc., 1920, 42, 2569—2570.

THE freezing point curve of mixtures of hydrogen peroxide and water shows that the compound $2H_2O$ H_2O_2 exists and has m.p. $-51°$ C.—J. F. S.

Autoxidation [of phosphorus]; Pressure limit o —— considered as a particular case of the inferior limit of explosion. II. [Explosion limits o acetaldehyde.] W. P. Jorissen. Rec. Trav Chim., 1920, 39, 715—719.

A COMPARISON of the influence of carbon dioxide or the pressure limit of phosphorescence of phosphorus and on the inferior limits of explosion of hydrogen and methane. In each case the influence of carbon dioxide is greater than that of nitrogen. The limits of explosion of mixtures of acetaldehyde and air were found to be 5·7 and 13·5% by vol., whereas with a mixture of 21% O_2, 60% CO_2, and 19% N_2 by vol. in place of air the limits were 8·1% and 11% of acetaldehyde by vol.—W. G.

Flake graphite; Separation of mineral matter from natural ——. W. C. Ratliff and J. D. Davis. Chem. and Met. Eng., 1920, 23, 1027—1028.

REMOVAL of mineral matter from flake graphite is specially desirable in the case of graphite dust in order to provide a marketable product for the manufacture of stove polishes, graphite paints and lubricants, and electrodes. If the finely ground graphite is agitated with paraffin oil and water, it agglomerates with the oil, and the mineral matter suspended in the water may then be separated. Lighter and more volatile liquids which are im-

iscible with water, such as benzene, toluene, and ırbon tetrachloride, are more effective than oil ıd more readily recoverable, and of these carbon ·trachloride gives the cleanest separation. The nounts of mineral matter retained after treatent by Alabama graphite containing originally [·68%, were 4·28% with oil, and 3·30—3·44% with ıe other liquids, while with Pennsylvania graphite ıe mineral matter was reduced from 10·03% to 43% after oil treatment, and to 5·54—5·71% after ·eatment with the other liquids. Fineness of rinding has an important bearing on the result; ı almost every case a smaller amount of mineral ıatter was retained by graphite which had been round for 20 hrs. than by that which had been round for only 8 hrs. The effect of grinding is ot so much to reduce the size of the flakes as to iminish their thickness and so expose the mineral ıatter between the laminæ.—W. J. W.

'raphite; Method for rapid analysis of ——. G. B. Taylor and W. A. Selvig. U.S. Bureau of Mines, Bull. 112, 1920, 43—45.

'HE following method is used at the Pittsburgh ,aboratory of the U.S. Bureau of Mines:—If much ;angue is present the sample is ground to pass hrough a 60-mesh sieve. Moisture is determined y heating 1 g. in a weighed platinum or porcelain rucible, ⅞ in. deep by 1¾ in. wide, for 1 hr. at 05° C. The crucible is cooled in a desiccator over ulphuric acid and the loss of weight noted. Volaile matter is determined by heating the dry ;raphite for 3 mins. in a muffle furnace at 800° C., ooling as before, and noting the loss of weight. ısh is determined by heating the non-volatile esidue at 800° C. until all the graphite is burned .way. Graphitic carbon is taken as the difference ›etween the sum of the percentages of moisture, ısh, and volatile matter and 100. Graphitic carbon n an ore is determined by heating 0·2—1·0 g. in a .00 c.c. evaporating dish with 25 c.c. of hydro-:hloric acid (1:1) on a hot plate for 15 min., filterng the mixture through ignited asbestos and washng the residue with hot water. The filter and ·ésidue are transferred to a porcelain or platinum ›oat, dried on a hot plate, transferred to a com-›ustion tube (containing fused lead chromate to ·etain any sulphur present), and burned in a stream ›f oxygen. The carbon dioxide formed is passed nto a weighed potash bulb containing 30% potas-ıium hydroxide solution and weighed. Graphitic :arbon is determined in a concentrate by placing)·2—0·5 g. of the sample in a small Erlenmeyer ‌łask, adding about 25 c.c. of ether, corking loosely, ınd allowing to stand for ½ hr., shaking at intervals. The mixture is filtered through ignited asbestos, the residue washed with alcohol and distilled water, then treated with acid to remove carbonates, and the determination continued as described for ores.
—A. B. S.

Liquefaction of air; Physical principles of the ——. R. Plank. Z. ges. Kälte Ind., 1920, 27, 1—8. Chem. Zentr., 1920, **91**, IV., 705.

In the liquefaction of air the cooling due to the Joule-Thomson effect for small differences of pressure has been found to be above ½ at 200° abs. over ¾ at 175° abs., and about 87% at 150° abs. of that produced by adiabatic expansion. Adiabatic expansion is never fully attained in practice.—W. J. W.

Hydrogen-helium mixtures. Ledig. *See* IIA.

PATENTS.

Nitric acid; Manufacture of ——. N. C. Hill and H. L. Moyler. U.S.P. 1,362,418, 14.12.20. Appl., 28.4.20.

In an apparatus for the continuous manufacture of nitric acid, which includes a rotating retort, the alkali nitrate is introduced midway into a flow of hot sulphuric acid, which gradually merges into a flow of molten sulphate. The nitric acid vapours are drawn off at a point near the origin of the sulphuric acid flow.—W. J. W.

Nitrogen oxides; Process for the catalytic conversion of ammonia into ——. Badische Anilin und Soda Fabr. G.P. 301,362, 9.3.15.

The catalyst consists of copper oxide mixed with a subordinate quantity of a compound of lead or manganese containing active oxygen. For example, 5 pts. of granular cupric oxide is soaked in 1 pt. of an aqueous solution of lead or manganese nitrate and the mass heated. By passing a 7% ammonia-air mixture over the catalyst heated to 750° C. a yield of over 90% of nitrogen oxides is obtained.
—A. R. P.

Nitrogen oxides; Process for melting solid —— *in the freezing apparatus for condensing nitrous gases.* Norsk Hydro-Elektrisk-Kvaelstofaktieselskab. G.P. 325,636, 29.8.19. Conv., 14.10.18.

So much nitrogen tetroxide is added that the heat furnished by its condensation is sufficient to melt the solidified nitrogen tetroxide, or, alternatively, nitric oxide is introduced, which combines with the solid nitrogen tetroxide to form the trioxide, which melts at a very low temperature.—A. R. P.

Nitrogen; Regenerative furnace for combustion of ——. Gewerkschaft des Steinkohlenbergwerks "Lothringen," and M. Kelting. G.P. 325,635, 31.12.19.

In a regenerative furnace for the combustion of nitrogen, at each side of the combustion chamber there is a heat regenerator consisting of two or more concentric tubes. One or both of the reacting gases are pre-heated in the regenerator on one side of the combustion chamber, whilst the regenerator on the other side is being heated by the exhaust gases from the furnace.—W. J. W.

Hydrobromic acid; Process for manufacture of —— *from bromine and hydrogen.* H. R. Napp. From A. Tschudi. E.P. 154,472, 6.1.20.

Bromine is vaporised in an electrically-heated quartz vessel, having a vertical quartz tube above it into which the bromine gas passes and comes in contact with hydrogen introduced through a lateral inlet. The mixed gases are ignited by bringing the tube to reaction temperature by means of an electrically heated spiral, after which the heat of reaction suffices to maintain the requisite temperature. To ensure that the gases are being admitted in molecular proportions, a sight glass is fixed in the quartz tube through which the colour of the flame can be observed. The hydrobromic acid is conducted to an absorption system.—W. J. W.

Ammonia-alum; Production of iron-free —— *from aluminium sulphate solutions containing ferric sulphate.* R. Gans. E.P. 132,510, 8.9.19. Conv., 21.9.17.

Ferruginous aluminium sulphate solution, which may be obtained by dissolving aluminous rock in sulphuric acid, is treated with an excess of ammonium sulphate dependent on the amount of ferric sulphate present. The solution is then caused to react with a base in such quantities as to convert the ferric sulphate, remaining in the solution after crystallisation of the ammonium alum, into basic ferric sulphate, such crystallisation being conducted under agitation with a view to the formation of small crystals; these are finally washed with ammonium sulphate solution. Alum prepared by this method contains considerably less than 0·1% Fe referred to the alumina content.
—W. J. W.

Blast-furnace slag; Arrangement for blowing air through —— in particular for recovering the sulphur as sulphur dioxide. L. H. Diehl. E.P. 139,173, 16.2.20. Conv., 24.9.17. Addn. to 139,172.

For the process of blowing air through blast-furnace slag described in the original patent, a trough is used consisting of sections of hæmatite iron in the shape of gutters, with external air chests, the sides of the gutters being extended upwards by slabs. In the sides of the gutter sections and in communication with the air chests are air nozzles which are directed obliquely downwards, by which means the slag is kept violently agitated without the formation of a crust at the bottom, the air chests serving to prevent the gutters melting, whilst at the same time the air becomes heated. Lateral inlets and outlets for the slag are so arranged that by means of an overflow level above them, forming a seal, communication with the outside air is avoided, and the gases can only escape through a gas outlet, which passes round the rear end of a vaulted roof beyond the blast zone, and is thus protected against choking by slag spray. The slag crusts can be scraped out through a door in the front of the trough, and openings in the air chests which can be closed by doors enable the air nozzles to be cleaned from outside.—W. J. W.

Magnesium hypochlorite; Production of solid basic ——. G. Kereszty and E. Wolf. E.P. 142,081, 2.2.20. Conv., 19.4.19.

To obtain a satisfactory yield of solid basic magnesium hypochlorite by passing chlorine into a suspension of magnesia in water, there should be 5½ mols. of excess magnesium oxide for every mol. of hypochlorite formed. A better yield is obtained at 20° C. than at lower temperatures, there being no appreciable quantity of chlorate formed. If, finally, the reaction mixture is either allowed to stand for a week in the dark, or is heated for 6—8 hrs. gradually to 80° C., practically 100% of the total active chlorine is found in the precipitate. While drying the latter carbon dioxide must be excluded.—C. I.

Potassium carbonate and sodium carbonate; Process for manufacture of —— by wet process. S. Lamm. E.P. 154,498, 2.3.20.

Finely ground potassium sulphate and barium sulphide are intimately mixed with granular potassium bicarbonate and added to boiling water in a heated vessel. The nascent potassium sulphide formed by interaction of the first two salts reacts with the bicarbonate without secondary reactions taking place, and gives a product of a high degree of purity. The solution is separated from the precipitate, concentrated, and crystallised. The residual barium sulphate is utilised for regenerating barium sulphide, and the hydrogen sulphide evolved is available for other purposes. Sodium carbonate is manufactured by an analogous method. —W. J. W.

Potassium bichromate and sodium bichromate; Manufacture of ——, and production of normal sulphates of potassium and sodium. R. L. Datta. E.P. 154,810, 5.1.20.

Potassium chromate liquor is heated and treated with acid potassium sulphate cake, the latter being added until conversion of chromate into bichromate is complete. The solution is filtered, the potassium sulphate separated, and the mother liquor is crystallised. Sodium bichromate may be similarly produced by the interaction of nitre cake with sodium chromate liquors.—W. J. W.

Ammonia; Production of ——. A. Rollason. E.P. 155,313, 17.6.19.

A producer, constructed with an outer shell surrounding the producer chamber and provided with a superheater, is charged with pulverised coke, anthracite, or hard coal, the fuel being kept at a uniform height by means of an internal bell arrangement. Air, saturated with steam, is preheated by passing through the superheater and outer shell and forced at slightly above normal pressure into the fuel bed, the temperature of this being kept below 950° C. by introducing steam. The gases leaving the producer, free from oxygen, are cooled to about 500° C. either by steam or by means of a cooling arrangement, and enter a decomposer consisting of a steel or cast iron outer tube lined with firebrick and an inner tube, into which the gases pass and in which they are heated to 550°—600° C. by hot gases which circulate between the two tubes, thus causing the dissociation of the nitrogen molecule into free atoms. The gases are then conducted into the inner tube of a converter which is charged with breeze or coke to which limestone has been added, and is kept at 700°—800° C. by hot circulating gases. The water vapour in the gases is dissociated, the oxygen combines with the carbon, and combination of the free nitrogen and the nascent hydrogen takes place, the gases leaving the converter being cooled to 90° C., and the ammonia recovered. The final gases may be utilised for combustion in furnaces to heat the superheater, decomposer, and converter. —W. J. W.

Magnesium carbonate; Process of and apparatus for manufacturing [basic] ——. B. B. Grunwald, Assr. to National Magnesia Manufacturing Co. U.S.P. 1,361,324 and 1,361,325, 7.12.20. Appl., 18.3.18.

Calcined magnesite is hydrated and treated with carbon dioxide under pressure. The resulting product, containing excess of carbon dioxide, is mixed with more calcined magnesite and the mixture heated to precipitate basic magnesium carbonate.—B. V. S.

Monazite sand; Treating ——. E. L. Knoedler, Assr. to Welsbach Co. U.S.P. 1,361,735, 7.12.20. Appl., 1.5.18.

The sand is heated with sulphuric acid and the hot mixture poured into a "drowning tank." —B. V. S.

Titanium hydrates [hydroxides]; Removal of undesired acid substances from ——. C. Jebsen, Assr. to Titan Co. A./S. U.S.P. (A) 1,361,866 and (B) 1,361,867, 14.12.20. Appl., 12.10.17.

The acid is removed by treating the precipitated titanium hydroxide with (A) a compound of a metal forming a neutral insoluble salt with the acid or (B) an alkali which forms a neutral soluble salt. —C. I.

Sulphur dioxide and metallic sulphates; Manufacture of —— from burnt pyrites. Zellstoff-fabrik Waldhof. G.P. 298,552, 5.10.16.

Burnt pyrites is heated with sulphuric acid or an acid sulphate until the mass becomes dry. The temperature is then raised until all the iron sulphate is decomposed into iron oxide and sulphur dioxide without decomposing other metallic sulphates such as those of zinc or copper. Any unroasted pyrites present in the charge is converted into iron oxide with evolution of a further quantity of sulphur dioxide. The residual mass is extracted with water to remove soluble salts and leave a fairly pure iron oxide. When sodium bisulphate is used in the process sufficient common salt is added to the solution to convert the salts of

the heavy metals into chlorides, and the sodium sulphate present is then removed by crystallisation or by freezing.—A. R. P.

Sulphur dioxide; Manufacture of liquid —— from sulphur dioxide diluted with other gases. Manufactures de Prod. Chim. du Nord Etabl. Kuhlmann. G.P. 325,473, 23.11.19.

Gases containing a small percentage of sulphur dioxide, *e.g.*, those obtained from roasting blende or pyrites, are compressed and then agitated with heavy tar oil free from anthracene, which absorbs the sulphur dioxide. The latter is removed from the oil by warming, and liquefied in the usual way. Coal-tar oil of sp. gr. 1 dissolves at atmospheric pressure and ordinary temperatures about a quarter of its weight of sulphur dioxide.—A. R. P.

Hydrogen sulphide; Process of separating —— from gases. Zschocke-Werke A.-G. G.P. 325,966, 31.7.17.

The gas is first sprayed with excess of a washing agent, and is then treated with a portion of the liquid in a centrifugal gas-washing apparatus.
—W. J. W.

Nitric acid; Production of ——. K. B. Quinan. U.S.P. 1,355,357, 12.10.20. Appl., 24.2.19.

See E.P. 131,029 of 1918; J., 1919, 718 A.

Salt; Manufacture of table ——. C. Dietz, Assr. to Chemical Foundation, Inc. U.S.P. 1,362,087, 14.12.20. Appl., 14.11.16.

See E.P. 18,125 of 1915; J., 1916, 963.

Tin; Oxidation of ——. [Manufacture of tin oxide.] D. de Ros. U.S.P. 1,362,237, 14.12.20. Appl., 9.8.20.

See E.P. 118,664 of 1917; J., 1918, 622 A.

[Calcium] cyanamide; Apparatus for the manufacture of ——. A. Duchemin. U.S.P. 1,363,096, 21.12.20. Appl., 15.7.19.

See E.P. 142,354 of 1919; J., 1920, 488 A.

VIII.—GLASS; CERAMICS.

Glass; Annealing of ——. L. H. Adams and E. D. Williamson. J. Franklin Inst., 1920, **190**, 597—631, 835—870.

When judged by an arbitrary standard of annealing—that the maximum optical path-difference in an annealed block shall not exceed 10$\mu\mu$ per cm.—the release of stress in glass during annealing at constant temperature may be represented by

$$\frac{1}{F} - \frac{1}{f} = At$$

where F is the stress at any time, t; f is the initial stress, and A is a constant for the particular glass at a particular temperature. The annealing time for optical glass is defined as the time required at a given temperature to reduce the stress from 50 to 2·5$\mu\mu$ per cm. Most of the important operations in glass annealing occur over a temperature range of about 150° C. which is limited at its upper end by the temperature at which the strain disappears in 2 mins. At temperatures below this annealing range very little permanent stress can be introduced during cooling. The permanent stress acquired during cooling is equal and opposite in sign to the temporary stress when the glass is being annealed, and in order to obtain glass free from internal stress it is necessary to prevent the release of stress during cooling. The best way to do this is to cool the glass slowly through the annealing range and more rapidly later. Hence, instead of the customary method of annealing in which the glass is cooled slowly from the upper end of the annealing range to room temperature, the authors prefer to maintain the glass for a sufficient time at a temperature at which it requires several hours to release the stresses and then to cool it rather rapidly. With the latter method the chances of failure during cooling are very low. For a plate of ordinary crown glass, 2 cm. thick, the lower end of the annealing range is 511° C., the cooling period 2·2 hrs., and the total time of heating and cooling is about 4½ hrs. For optical glass slabs the rate of cooling should never exceed $10/a^{2}$° C. per min., where a is half the thickness of the slab in cm. The saving in time afforded by the authors' method is increasingly important with large pieces of glass. Tables of annealing schedules for various optical glasses are given.—A. B. S.

Iodine and bromine vapours; Permeability of glass to ——. J. B. Firth. Chem. Soc. Trans., 1920, **117**, 1602—1603.

Iodine and bromine do not diffuse through a glass partition under ordinary conditions. In an extreme case the diffusion of iodine through a glass bulb 0·21 mm. thick was observed after 9½ years, during 100 days of which the bulb had been heated to 360° C. Even under these conditions there was no evidence of the diffusion of bromine.—G. F. M.

Flake graphite; Refining Alabama —— for crucible use. F. G. Moses. U.S. Bureau of Mines, Bull. 112, 1920, 46—74. (*Cf.* J., 1919, 633 A.)

Investigations on refining crude graphite concentrates showed that no one refining treatment is equally applicable to all concentrates on account of the different characteristics of the crude graphites and their impurities. When the impurities are free or soft, they can easily be separated by grinding, but hard impurities interlaminated with the graphite are more difficult to separate. An aspirator and pneumatic jig are only useful for removing the coarse, hard and free impurities. An electrostatic separator or pebble mill, followed by flotation, may be used for all Alabama graphite concentrates, but a buhr mill is also essential in "finishing" the graphite and preparing it for the removal of interbedded impurities. The use of this machine presupposes that the impurities are ground much more finely than the graphite and so are separated in the subsequent screening. It should be possible to keep the recovery of graphite coarser than 100-mesh at 70% or more of the total carbon in the original concentrate. If only high-grade graphite is sent to the buhr mill it is not difficult to obtain a final product with over 90% of carbon. Care must be taken not to produce too much fine flake which will pass through a 100-mesh sieve. A loss of only 20% of fine graphite is not objectionable. Coarse grit in the material supplied to the buhr mill is the chief cause of loss through grinding the carbon too fine for use in crucibles, *i.e.*, finer than 100-mesh.—A. B. S.

Flake graphite [for crucibles]; Tentative specifications for ——. G. D. Dub. U.S. Bureau of Mines, Bull. 112, 1920, 38—41.

Tentative specifications suggested by the Columbus Experiment Station of the U.S. Bureau of Mines for No. 1 flake graphite are as follows:—The graphite carbon content, determined by weighing the residue left after heating the dried sample for 3 mins. at 800° C., should not be less than 85%. The cumulative percentage residues on a series of screens should be: 35% on 35 standard mesh, 50% on 65 standard mesh, and 100% on 100 standard mesh. The permissible allowance is not more than 3% through a 100-mesh screen.—A. B. S.

Graphite. (1) Ratliff and Davis. (2) Taylor and Selvig. *See* VII.

PATENTS.

Glass compositions and articles made therefrom. Corning Glass Works, Assees. of E. C. Sullivan and W. C. Taylor. E.P. 145,428, 17.6.20. Conv., 26.2.17.

CLAIM is made to a glass containing silica, soda, and at least one oxide of a divalent alkaline-earth, the molecular ratios falling within the following limits: silica 100, alkali oxide 20 to 36, and oxide of divalent alkaline-earth 6 to 36. Magnesia forms at least 40% of the alkaline-earth oxide content. Magnesia glasses have lower coefficients of expansion than lime glasses of equal softness and are suitable for electric lamp bulbs.—H. S. H.

Brick dryers; Supply of heat to tunnel ——. T. Entwisle. E.P. 154,966, 16.8.19.

IN an improved method of supplying heat to tunnel brick dryers, hot air from the cooling chambers of a continuous kiln is passed through an auxiliary flue to a mixing chamber provided with a cold air inlet and a fan, and thence through ducts below the tunnel dryer and opening up into the latter. The passage of the hot gases is controlled by dampers.—A. B. S.

Drying machines [for pottery]. T. Allsop and W. W. Sibson. E.P. 154,896, 3.9.19.

A CASING is divided by partitions into a heating compartment, a drying compartment, and an auxiliary compartment. The goods to be dried, *e.g.*, pottery, are moved through the second and third, and the drying medium, such as air, circulates between the first and second compartments. The goods are supported on long carriers, which extend practically across the full width of the casing, space being left only for a pair of conveyor chains which support the carriers and pass very slowly up and down several times over sprockets in the drying chamber, returning through a duct underneath and upwards through the auxiliary chamber, where they are unloaded and charged with fresh goods. The heating chamber may be provided with cross tubes heated by steam, and the air circulated by a fan in the partition between the heating and drying chambers.—B. M. V.

Tunnel kilns or furnaces. R. C. Metcalfe. E.P. 155,164, 7.4.20.

A TUNNEL kiln is provided with a single reciprocating truck to transport goods back and forth between a high temperature zone in the kiln and an inlet and outlet disposed laterally at right angles to, and at opposite ends of, the high temperature zone. The ends of the kiln chamber are so shaped that the truck prevents gases in the high temperature zone from passing out at either end of the chamber.—A. B. S.

[Tunnel] ovens or kilns; Gas-fired —— for tiles, pottery, etc. J. H. Marlow. E.P. 155,190, 30.7.20.

A GAS-FIRED tunnel oven has a number of burners of different diameters arranged to produce a gas flame at each side of the oven, and two combustion chambers at each side of the oven. Each combustion chamber communicates with a series of air pipes so that when the oven has reached a predetermined temperature the air in the pipes can be cut off and replaced by air heated recuperatively in a second series of pipes which supply heated air to the second combustion chamber on each side of the oven. The flames and products of combustion then pass over the auxiliary burners and away to the chimney.—A. B. S.

Furnace structures [linings]. J. H. Cumpsty. E.P. 155,315, 20.6.19.

A MONOLITHIC furnace lining or other structure is made by arranging suitable metal reinforcement in a mould and filling the latter with a thin cement composed of magnesia and sodium silicate or like binding material, or with a mixture of broken magnesite bricks or magnesite and 10% of sodium silicate. The moulded article is dried and fired and is then ready for use.—A. B. S.

Pottery ware [; Ornamenting ——]. A. P. Morris. E.P. 155,332, 15.8.19.

BLACK Burmese pottery, in which the black coloration is produced by the deposition of carbon from the smoke towards the end of the burning period, may be ornamented by removing the carbon from predetermined areas by oxidation and so revealing the natural colour of the burned clay. The oxidising or decarbonising material may consist of potassium chlorate, potassium nitrate, or the like made into a paste and painted on the ware, which is then re-fired at a low temperature (400° C.) sufficient to effect the oxidation but not to cause the oxidising agent to adhere to the ware. The re-fired ware when cold is freed from any excess of oxidising material, which usually flakes off.
—A. B. S.

Pots; Impts. in and in the manufacture of acid —— to be employed in the production of white lead. H. T. Arrowsmith. E.P. 155,373, 17.9.19.

EACH pot is moulded with two or more projections on its upper edge, and after glazing inside the pots are stacked with their mouths together. The projections prevent the pots from sticking owing to the glaze flowing on to the edges of the pots. Each pair of pots forms a chamber and the glazed interior is thus protected from contamination during firing so that no saggars are necessary.—H. S. H.

Refractory article and process of making same. F. J. Tone, Assr. to The Carborundum Co. U.S.P. 1,362,274, 14.12.20. Appl., 24.2.20.

A HIGHLY refractory material consists essentially of a burnt mixture of zirconia and sillimanite.
—H. S. H.

Refractory material and process of making it. Refractory article and process of making same. O. Hutchins, Assr. to The Carborundum Co. U.S.P. (A) 1,362,316 and (B) 1,362,317, 14.12.20. Appl., 7.1 and 24.3.20.

(A) A HIGHLY refractory material consists essentially of a burnt mixture of zirconia and alumina. (B) A shaped highly refractory article is formed of a burnt mixture containing zirconia and chromite.
—H. S. H.

Glass charges; Method of getting viscous ——. O. M. Tucker and W. A. Reeves. E.P. 131,586, 5.8.19. Conv., 12.8.18.

Glass; Apparatus for manufacture of articles of —— from glass tubing. W. A. Whatmough. E.P. 155,433, 10.11.19.

IX.—BUILDING MATERIALS.

PATENT.

Cement; Slow setting, fat and water proof —— and method of producing same. H. D. Baylor. E.P. 155,431, 8.11.19.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steel; Inclusions and ferrite crystallisation in ——. *II. Solubility of inclusions.* E. G. Mahin and E. H. Hartwig. J. Ind. Eng. Chem., 1920, **12**, 1090—1095. (*Cf.* J., 1919, 864 A.)

A CONSIDERABLE number of alloys and special steels were turned into small rods and driven into holes in carbon steels, the specimens being then heated to temperatures above the transformation range for the steel. The section of the slowly cooled piece showed, in nearly every case, ferrite segregation around the insert, but the ferrite ring varied greatly in width. It is suggested that the special element, elements, or compounds present in the insert diffused into the steel and caused, in varying degrees, separation of ferrite from the austenitic solution when the latter was cooling through the transformation range. If this hypothesis is correct, the importance of the uniform distribution of all elements of carbon and alloy steels is evident, as otherwise it is not possible to have uniform carbon distribution and the finished piece cannot be brought into its best condition by any ordinary heat treatment.—W. P. S.

Mild steel; Intercrystalline fracture in ——. W. Rosenhain and D. Hanson. J. Iron and Steel Inst., 1920, **102**, 23—37.

FOUR cases of intercrystalline fracture in mild steel are recorded. Some steel wrapper plates from the combustion chamber of a marine boiler cracked between the rivet holes near the edges. The explanation in this case is that near the surface free cementite occurred between the ferrite crystals. The same cause led to a similar failure in a $\frac{1}{4}$ in. mild steel plate from the drum of a water-tube boiler. Intercrystalline fracture in steel plates from a high-pressure marine boiler around and between the rivets is ascribed to the application of long-continued stresses over a period of years. A piece of the plate nicked and broken in several hours showed no intercrystalline weakness. The last case was a mild steel tube which had failed when under no stress at 300° C. in a nitre bath. Cold-drawing stresses had been left in through insufficient annealing which led to failure.—F. C. Th.

Steel [and other metals]; Effect of nitrogen [ammonia] on ——. O. A. Knight and H. B. Northrup. Chem. and Met. Eng., 1920, **23**, 1107—1111.

A PRELIMINARY investigation of the effect of ammonia at 650° C. on various metals and alloys, as indicated by their microstructure, showed that tungsten, chromium-vanadium steels, stellite, nichrome, and Monel metal, are not affected, or only slightly attacked. Wrought iron and low-carbon steels are readily attacked; high-carbon steel is much more resistant, and white cast iron is affected on the surface. The results have only a negative value, as the metals which are not acted on are unsuitable for use in making containers for ammonia either as regards price or physical properties. Nine samples of annealed steel wire were selected for physical examination, six of them being first heated in ammonia gas at 650° C., and of these, three were further heated in hydrogen at 650° C. The treated samples showed a diminished tensile strength and reduced elongation; hydrogen treatment partly restored the normal properties, and entirely removed the irregular "white layer." An investigation was made of the effect of ammonia on all grades of carbon steel. The samples were case-hardened at 950° C., then cut in half in the centre of the longest dimension, the exposed surface varying in carbon from 0·07% near the centre to 1% on the outside. One portion was ground, heated in ammonia at 650° C. for 12 hrs., and furnace-cooled; it was then cut on a plane normal to the previous exposed surface, mounted in an alloy of low fusion point and polished; as no effect was observed, the sample was etched with 4% nitric acid in absolute alcohol. The samples then showed a uniform outside layer which was the same in both the high- and low-carbon areas. Longer etching merely intensifies the corrosive action on the outer three-fifths of the layer, but on the inner two-fifths it develops a crystalline structure of a columnar nature. The base of these crystals forms a sharp demarcation from the pearlitic structure beneath. The outer layer is characterised by extreme hardness and brittleness. In the high-carbon area the pearlitic structure at the base of the columnar crystals appears to be normal; in the low-carbon region, however, the pearlitic layer is succeeded by a layer of apparently normal ferrite grains, and below this the ferric grains contain a number of "nitrogen needles," proving that nascent nitrogen has a greater penetrating power in low-carbon than in high-carbon steels.—W. J. W.

Steel, iron, and cast iron; Metallographic methods for determining the nature of the non-metallic inclusions in ——. M. Matveieff. Rev. Mét., 1920, **17**, 736—752.

To detect the presence of ferrous oxide inclusions the polished specimen is heated to dull redness in hydrogen and again polished, when the inclusion, if due to ferrous oxide, disappears. Inclusions of sulphides are best recognised by etching the specimen with a 0·2% solution of oxalic acid, which attacks manganese sulphide and yields a rose-coloured tint with ferrous sulphide. Silicate inclusions are not attacked by either of the above reagents and may be recognised by their dark colour. The distribution of phosphorus in the metal may be examined by etching with a mixture of 100 c.c. of methyl alcohol, 2 c.c. of hydrochloric acid, 1 g. of copper chloride, 4 g. of magnesium chloride, and 18 c.c. of water, when the parts richest in phosphorus remain clearer than the rest of the metal. Details are given of the use of the above reagents in discovering the reasons for the failure of ingots of iron and steel.—A. R. P.

Steel; Electrometric method for detecting segregation of dissolved impurities in ——. E. G. Mahin and R. E. Brewer. J. Ind. Eng. Chem., 1920, **12**, 1095—1098.

A METHOD is described for measuring the electrode potential of a single grain or microscopic point on a metal specimen. When the method is applied to a piece of steel containing a segregated ring of ferrite, produced by heating in contact with aluminium bronze, the average values for the ring are 0·051 volt lower than for ferrite in the unaffected part of the metal. This indicates a different degree of purity for ferrite under the two conditions.—W. P. S.

Nickel-iron alloys; Constitution of ——. D. and H. E. Hanson. J. Iron and Steel Inst., 1920, **102**, 39—64.

THE diagram of the changes which occur below the solidus for pure iron-nickel alloys (maximum carbon content 0·046%) shows that up to 9% Ni this is at room temperatures in solid solution. Between 9 and 32% Ni a eutectoid horizontal occurs at about 350° C., the eutectoid point being at about 25% Ni. The two curves above 30% Ni lie quite close to each other and join at about 700° C. Very long soakings are required to produce the equilibrium structure.—F. C. Th.

Aluminium; Influence of iron on the mechanical properties of cast ——. L. Guillet and A. Portevin. Rev. Mét., 1920, **17**, 753—756.

THE presence of iron in cast aluminium increases

the hardness and diminishes the ductility, metal containing about 4% Fe being so brittle that it cannot be bent without breaking. Figures are given showing the results obtained for aluminium containing 0·7 to 3·9% Fe in the Brinell, repeated impact, and notched bar tests. Photomicrographs show that the alloys have a eutectic structure when the iron content is between 0·7 and 1·7%, while those with higher proportions of iron contain large numbers of needles and star-like aggregates.
—A. R. P.

Sheet zinc; Occurrence of a foliated appearance on strips of ——. E. H. Schulz and R. Melaun. Forschungsarb. Geb. Ing., Sonderreihe M, [1], 23—27. Chem. Zentr., 1920, **91**, IV., 622.

On bending and twisting several different kinds of sheet zinc it was noticed that the surface split up into small leaves, giving the material a foliated appearance. While this could be traced partly to segregation of the lead in rolling, it otherwise did not appear to have any connexion with the chemical composition of the metal and was probably due to the method of rolling, the metal having been rolled out in fewer stages than usual, thus giving rise to temperature differences between the outer surfaces and the interior. This produced small longitudinal cracks along the edges of the rolled sheet and on the broken edges of a fracture, and on bending the metal caused the foliated appearance. No explanation, however, could be found for the fact that Rhenish and Belgian zincs behave worse under these conditions than zinc of similar composition produced in Upper Silesia.—A. R. P.

Forged zinc; Influence of the forging temperature on the tensile properties of ——. E. H. Schulz and R. Fiedler. Forschungsarb. Geb. Ing., Sonderreihe M, [1], 27—29. Chem. Zentr., 1920, **91**, IV., 622—623.

Tests made on zinc rods (containing 1·3% Pb and a trace of iron) forged down from 120 mm. to 50 mm. diameter at various temperatures showed that the highest tensile strength and elongation were obtained when the forging temperature was 120° C. As this temperature was increased the ultimate stress altered but little, but the elongation and resistance to impact of the resulting bar were considerably decreased, while the metal became coarser grained. Metal containing more iron must be worked at a higher temperature than pure zinc, and if worked just below 120° C. it gives a greater elongation.—A. R. P.

Forged zinc; Development of a coarsely crystalline structure in —— *by heating.* E. H. Schulz and O. Zeller. Forschungsarb. Geb. Ing., Sonderreihe M, [1], 32—38. Chem. Zentr., 1920, **91**, IV., 623.

By heating forged zinc for ½ hr. at gradually rising temperatures from 100° C. upwards and examining the fracture and microscopic structure of polished and etched surfaces, it was established that, at a definite temperature, depending on the forging temperature of the sample, but at least 140° C., a fairly sharply separated zone of larger-grained metal developed round the outer edges of the test-piece. As the temperature was raised this zone gradually increased in extent until at 200° C., or higher, according to the original forging temperature, complete recrystallisation of the metal took place. As the grain of the metal became coarser the tensile strength, and especially the elongation, decreased, the latter very considerably after recrystallisation had set in, but no change was noticed in the Brinell test. Heating zinc to 150°—200° C. has a bad effect on the elongation. The tensile strength is not appreciably altered by heating for ½ hr. at 200° C., but at 300° C. a considerable decrease in strength is produced.—A. R. P.

Zinc; Behaviour of —— *in the impact test.* E. H. Schulz and R. Fiedler. Forschungsarb. Geb. Ing., Sonderreihe M, [1], 29—31. Chem. Zentr., 1920, **91**, IV., 622.

Forged zinc with a tensile strength up to 20 kg. per sq. mm. and an elongation of 30% or more gave results in the impact test with a notched bar varying from 0·55 to 0·75 kg.-m. per sq. cm., and this figure could not be improved upon by preparing the specimen by other methods, by further refining, or by alloying the zinc with other metals. The results obtained with bars with V-shaped notches decreased as the angle of the notch increased, and the broken bars showed a short granular fracture. Bars with a circular notch had a resistance several times as great as those with angular notches, and the fractured surface was very jagged. Tests at various temperatures showed that the resistance of zinc to impact decreased with fall of temperature.
—A. R. P.

Forged and rolled zinc [; Effect of addition of copper and aluminium on mechanical properties of ——]. E. H. Schulz and R. Melaun. Forschungsarb. Geb. Ing., Sonderreihe M, [1], 38—42. Chem. Zentr., 1920, **91**, IV., 621—622.

Addition of 2½% Cu to forged zinc increases the tensile strength and hardness of thick bars to an extent depending on the temperature of forging, but does not appreciably improve the ductility or the toughness. Similar results are obtained by the addition of aluminium up to 4·4%, but in this case the metal appears to be more brittle. Thick plates that have been rolled from 30 cm. down to 1 cm. have good tensile strength and ductility combined with a low hardness number if 2% of copper has been alloyed with the metal. Addition of aluminium does not give such good results, it being necessary to add more than 4% Al to get the same effect as with 2% Cu, and even then, for the same tensile strength the elongation is less than that of the copper alloy. According to the particular method of working forged zinc with 2% Cu, the elongation and contraction of area vary from 9 to 30%.—A. R. P.

Brass; Influence of gases on high-grade ——. T. G. Bamford and W. E. Ballard. J. Inst. Metals, 1920, **24**, 155—200.

At 300° C. brass absorbs sulphur dioxide, but at higher temperatures, *viz.*, between 950° and 1050° C., and low partial pressures, the gas is eliminated from the metal. Thus the metal to be sound must be poured at such a temperature as to permit it to remain entirely fluid in the mould for a few moments. The conclusions reached regarding the solubility of hydrogen in 70:30 brass are: Between 500° and 900° C. the gas is absorbed in very large quantities depending on the temperature, pressure, and character of the surface. The larger part of the gas absorbed is retained on cooling, but much may be removed by treatment with a neutral gas at 600° C. or above. It is considered that in ordinary foundry practice with a coke fire and natural draught, it is impossible seriously to impair the mechanical properties of the casting by overheating. Cooling to within 40° C. of the liquidus will certainly ruin the mechanical properties of the casting by making it porous. In casting tubes a higher casting temperature is required than when casting solid ingots—at least 1150° C. in the case of 70:29:1 tubes. Exceptionally prolonged heating of the metal in the furnace does not impair the mechanical properties of the brass but results in a high loss of zinc. The casting temperature rather than the furnace treatment is believed to be the important factor in regard to the mechanical properties of the metal.—F. C. Th.

Beta brass; Behaviour of —— when cold-rolled. F. Johnson. J. Inst. Metals, 1920, 24, 301—314.

The brass examined contained 44·4% Zn. After casting the ingot was annealed for 1 hr. at 650° C. and then reduced in cross-section by 50% without further heat treatment. As a result of the rolling the maximum stress rose from 25·5 tons for the cast and 22·7 tons for the annealed alloy to 38·2 tons per sq. in., the elongation fell from 17% (cast) and 27% (annealed) to 8·6%, and the Brinell hardness (500 kg. load) rose from 95 (cast) and 86 (annealed) to 173. The microstructure of the alloy in the annealed condition consisted of the β-phase exclusively. After the cold rolling the crystals were traversed by numerous lamellæ (analogous to the Neumann lamellæ observed in meteorites and in ferrite which has been subjected to shock), showing faulting. When the cold-rolled brass was subsequently annealed for 30 mins. at 400° C. it was along these lamellæ that the α-phase made its appearance. The influence of annealing for 30 mins. at different temperatures after cold rolling upon the harness is shown in the following table:—

Temperature of annealing, °C.	Brinell hardness. 500 kilos.	1000 kilos.	Shore (magnifier hammer).
As rolled	173	192	55
250	100	129	24
300	100	129	23
400	93	—	20

F. C. Th.

Admiralty gun-metal; Influence of increasing proportions of antimony and arsenic respectively upon the properties of ——. R. T. Rolfe. J. Inst. Metals, 1920, 24, 233—283.

In sand-cast gun-metal the effect of a progressive increase in the antimony content is to produce a lowering of the strength and ductility, the alloy become harder and more brittle. With 1% Sb the maximum stress is about 15 tons per sq. in. and the elongation just under 7%. For material required to attain the Admiralty standard it is considered that 0·75% Sb is the maximum permissible. Up to 1·5% Sb does not appear to exert any definite influence on the soundness of the castings or on the microstructure. In chill castings the effects are similar. In the case of metal which has been twice melted, chill castings containing increasing amounts of antimony are increasingly unsound, especially with 1% or more of that element, and 0·75% is again considered to be the maximum figure allowable. The effect of arsenic on sand-cast gun-metal once melted is also to produce a progressive falling off of strength and ductility. For the maintenance of a safe margin over Admiralty specifications a maximum of 0·3% As should not be exceeded. Where the alloy is remelted the bad effects of the arsenic are not so pronounced, and the metal may be melted once and cast into ingots and a second time into castings. Up to 1·0% As does not appear to affect the soundness of gun-metal chill castings if these are melted once only. In the case of remelted metal chill castings become less and less sound as the arsenic content is raised, and a limit of 0·4% is suggested.—F. C. Th.

Manganese bronze; Note on a failure of ——. J. H. Dickenson. J. Inst. Metals, 1920, 24, 315—332.

Some peripheral projections of the end plate of a turbo-alternator rotor made of cast manganese bronze failed near soldered joints. The machine had run hot in service and the fracture of the bronze was clearly intercrystalline. Any fusible metal will cause manganese bronze to fail in a similar way provided that the fusible metal has been molten and that the bronze is under even a slight tensile stress. However tough the bronze is away from the solder, it will under these conditions act in its vicinity as a typical brittle substance. The fusible metal passes between the crystals, which part without appreciable deformation. Although the bronze which failed was of the β type, α-brasses will fail in a similar manner, and these alloys should not be used for the purpose mentioned or in electrical or other work where heating may occur and where solder or other fusible metal is present.

—F. C. Th.

Tin; Precipitation of —— by iron. N. Bouman. Rec. Trav. Chim., 1920, 39, 711—714. (*Cf.* J., 1920, 569 A.)

A reply to Kolthoff (J., 1920, 747 A) in which the author gives an account of certain new experiments in support of his views.—W. G.

Tin-antimony-copper alloys; Constitution and structure of ——. O. F. Hudson and J. H. Darley. J. Inst. Metals, 1920, 24, 361—371.

The size of the cuboid γ-crystals depends on the rate of cooling and only indirectly on the casting temperature. The latter factor, however, determines the grouping of the primary ϵ constituent, whilst the size of these crystals is a function of the rate of cooling. It is possible that the effect of the casting temperature may be the result of some molecular arrangement in the liquid state, though it is more probable that convection and other currents by breaking up the grouping formed first play a very large part. Vigorous stirring during casting produces a structure like that which results from a low casting temperature even when the latter is high. The casting temperature should not exceed 50° C. above the temperature at which solidification commences, or, say, 300°—350° C. for an alloy containing 89% Sn, 8·7% Sb, and 2·3% Cu.

—F. C. Th.

Crystal growth and recrystallisation in metals. H. C. H. Carpenter and C. F. Elam. J. Inst. Metals, 1920, 24, 83—154.

The work relates to aluminium and an alloy of tin and antimony containing about 1·5% Sb. This alloy is of special value for the study of crystal growth and recrystallisation, since if re-arrangement of the crystal system occurs on heating a polished and etched specimen to 150°—200° C. both the new and the old boundaries can be seen. The more important conclusions arrived at are: Neither crystal growth nor recrystallisation takes place unless the metal has been subjected to plastic deformation, *i.e.*, they do not occur in castings. Further, they do not occur unless the metal is heated to a certain minimum temperature and for a certain time. The effects of work vary according to the degree of deformation, *i.e.*, twin crystals or slip bands may be produced, but no crystal growth, or twins or slip bands may be produced with crystal growth on heating, or twins or slip bands may be produced, or entire recrystallisation on heating. The degree of deformation required to produce each of these types of effects is less as the temperature of heating is higher. There is no evidence that when equilibrium is reached the whole piece of metal will consist of a single crystal, but a certain definite degree of growth, dependent on the deformation, results for each temperature and time of reheating. Recrystallisation commences from a few points at the crystal boundaries of the old distorted crystals, and spreads through the mass. The recrystallisation is then followed by growth of the new crystals into each other, and crystals can both grow and be grown into at one and the same time. A large crystal may grow into a small one or *vice versâ*. The orientation of the crystal does not affect crystal growth. Growth always occurs by slow boundary migration and not by sudden coalescence.

—F. C. Th.

Metals; Crystallisation of —— by electrolytic deposition and certain connected phenomena. A. H. W. Aten and L. M. Boerlage. Rec. Trav. Chim., 1920, 39, 720—735.

THE conditions governing the form of the deposit obtained by electrolytic deposition of a metal from a solution of its salt are examined particularly for the case of the deposition of silver from a solution of its nitrate. The formation of different types of crystalline deposits or of a homogeneous layer is regulated by three factors, namely, number of nuclei, velocity of their growth, and variation of the polarisation tension with current density. The number of crystals per sq. mm. of cathode surface is practically a linear function of the intensity of the current, except when the current density becomes too great, the number being the greater the more dilute is the silver nitrate solution. It is only in the case where the polarisation tension is small that isolated crystals can be formed. The formation of a uniform deposit of a metal on an irregular object is regulated by the magnitude of the variation of the polarisation tension with the current density, a high value of $\Delta e / \Delta i$ giving a homogenous, flexible deposit. The addition of potassium nitrate, nitric acid, or gelatin to the solution of silver nitrate very considerably increases the number of crystals formed on a given area of the cathode.—W. G.

Corrosive action of chlorine-treated water. Clark and Iseley. *See* XIXB.

PATENTS.

Iron; Process for building up or growing of —— upon steel or other surface. S. O. Cowper-Coles. E.P. 154,282, 6.8.19 and 13.1.20.

THE required thickness of iron is deposited electrolytically from a hot saturated ferrous sulphate solution by immersing the part or parts to be restored in an electrolytic vat, the part which is not to be coated being protected by rubber or wax, or having the surface sulphided or oxidised so that any deposit is non-adherent. The deposited iron is annealed to produce soft tough iron which can be converted into steel by cementation. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 11,393 of 1889, 15,524 of 1900, 28,746 of 1910, 16,565 of 1913, 8795 of 1914, and 116,509; J., 1890, 812; 1911, 752; 1914, 650; 1918, 473 A.)—J. W. D.

Ferrous metals; Electrical treatment of —— during casting. J. H. Wickett. E.P. 154,711, 3.9.19.

THE cavities in the moulding box are arranged in a more or less regular annulus, and a transformer core is inserted through the annulus out of contact with the molten metal and at an angle to the plane of the annulus, the core carrying a primary winding and the molten metal forming the secondary and being heated by the current induced in it.

—J. W. D.

Puddled iron; Manufacture of ——. J. E. Fletcher. E.P. 155,042, 18.9.19.

PIG-IRON or pig-iron and iron or steel scrap melted in a furnace, or cold, is treated and partially refined in an open hearth refining furnace, and is subsequently finished and balled in puddling furnaces, and the puddled iron is hammered or pressed or rolled by steam-driven power machinery. The open-hearth and puddling furnaces are heated by means of pulverised coal or a mixture of pulverised coal and oil, and the waste gases from the furnaces are utilised in heating the steam generators for the machinery.—J. W. D.

Steel; Manufacture of ——. A. H. Henderson. U.S.P. 1,361,383, 7.12.20. Appl., 2.10.18.

METAL heated in a furnace or converter is brought into contact with chloride of lime, anhydrous aluminium oxide, and anhydrous borax.

—J. W. D.

Cast-iron; Transforming molten iron into pure —— in the electric furnace. Gräflich von Landsbergsche Elektrostahl und Metallwerke G.m.b.H. G.P. 309,252, 16.12.17.

MOLTEN iron that has been purified in the electric furnace is tapped into a ladle from which, after settling and holding back the slag, it is poured back into the furnace while at the same time a stream of finely divided charcoal or the like is charged in to carburise the metal.—A. R. P.

Ores and oxygen compounds utilised as ores; Reduction of ——. F. M. Wiberg. E.P. 130,334, 23.7.19. Conv., 23.7.18.

THE ore, in particular iron ore, is reduced by a gas containing carbon monoxide which moves through the furnace in a direction opposite to that of the ore. The reduction process is divided into two stages, a portion of the gas being removed before passing through the whole mass of ore contained in the furnace and forced through a gas producer containing heated solid carbonaceous matter in order to regenerate carbon monoxide before re-introducing the gas into the furnace. The remainder of the gas passes through the whole charge of ore and exerts a further reducing action. The process may be carried out in a shaft furnace divided into three sections. A portion of the reducing gas is withdrawn at the upper end of the lowest section and is passed through a gas producer and then re-introduced at the bottom of the shaft. In the uppermost section the ore is heated to the reducing temperature by the combustion of gases rising from the lower sections of the shaft.

—J. W. D.

Chromium or alloys of chromium; Production of ——. Aktiebolaget Ferrolegeringar. E.P. 135,187, 10.11.19. Conv., 15.11.18.

SILICO-CHROMIUM alloy containing more than 10% Si is bessemerised in a converter lined with substances containing chromic oxide, without the application of extraneous heat, in the present of substances capable of forming silicates, whereby chromium alloys low in carbon and silicon are produced.

—J. W. D.

Electric furnaces for the production of zinc. B. Raeder, and A./S. Zink. E.P. 139,160, 3.2.20. Conv., 15.2.19.

THE furnace comprises three superposed chambers through which the charge passes successively. The electrodes, which are enclosed in tubes for protection from the flame in the flame or heating chamber, project from the top of the furnace through the upper drying chamber and intermediate heating chamber into the lower reduction chamber. The opening for the electrode in the roof of the reduction chamber serves also as an opening for feeding the charge, and the space round the electrode in the flame (heating) chamber is filled with pulverised charge to render the electrode opening gas-tight.

—J. W. D.

Zinc from ores; Process of extracting ——. F. Laist and J. O. Elton, Assrs. to Anaconda Copper Mining Co. U.S.P. 1,362,166, 14.12.20. Appl., 5.1.20.

THE process is cyclical and consists of leaching the ore with a quantity of dilute sulphuric acid which is insufficient for complete extraction of the zinc, purifying the zinc sulphate solution, and producing from it by electrolysis metallic zinc and a dilute acid solution, a portion of which is returned to the ore-leaching operation, and the other portion

applied to leaching the residue from the primary leaching operation.—T. H. Bu.

Furnaces; Oil fired [recuperative] ——. J. Lambot. E.P. 141,055, 31.3.20. Conv., 3.4.19.

A FURNACE for melting metals is provided with detachable heads at each end, between the recuperator and melting hearth, the joints being made gas-tight by means of sand. The detachable heads carry detachable hollow plugs, each containing an adjustable oil burner mounted on an interior support, so that the oil flame can be directed downwards on the bath of metal.—B. M. V.

Open-hearth furnaces; Reversible ——. C. D. Fuller. U.S.P. 1,362,412, 14.12.20. Appl., 8.7.20.

IN a reversible open-hearth furnace means are provided for closing the side passages to the stack, and for producing a positive auxiliary circulation while the passages are closed.—W. J. W.

Furnace; Soft-metal ——. J. B. McClain. U.S.P. 1,362,429, 14.12.20. Appl., 16.8.20.

A FURNACE suitable for melting aluminium or other soft metals is provided with a bowl projecting downwards into the furnace body and spaced therefrom. The products of combustion rising from the firebox pass through an opening in the wall of the bowl and over the metal in it.—T. H. Bu.

Furnace [; Metal-working ——]. H. D. Hibbard. U.S.P. 1,362,532, 14.12.10. Appl., 1.11.19.

A METAL-WORKING furnace comprises a vessel with a number of pockets or containers. When the vessel is rocked the molten charge is poured from one pocket to another over the intervening dam, whereby reaction between the elements of the charge is promoted. When this reaction is completed the charge is discharged in solid form through a door. —T. H. Bu.

Electro-deposited metals. C. P. Madsen. E.P. 142,432, 5.8.19. Conv., 26.4.19.

"NICKEL metal" or substantially pure nickel is produced in an electro-deposition bath containing a sulphate and a chloride of the metal, an agent, *e.g.*, sodium sulphate, adapted during the operation of electro-deposition to yield finely divided hydroxide of the metal, boric acid in solution, and a finely divided hydroxide in suspension. The temperature of the operation is 130° F. (54° C.) and the cathode employed is adapted to be intermittently or periodically exposed to a gaseous medium such as air, the time of exposure being not long enough to cause the successive deposits to separate.—J. W. D.

Metals; Extracting —— from metallic compounds, ores, foundry products, furnace dust, and the like. F. Krupp A.-G. Grusonwerke. E.P. 144,728, 11.6.20. Conv., 3.6.19.

THE material to be treated is reduced to a fine state of subdivision and intimately mixed either dry or wet with sodium chloride also reduced to a fine state of subdivision, and the mixture heated in a furnace to the volatilisation temperature of the sodium chloride. The volatilised metal is collected. When the process is applied to lead zinc ores, lead and associated silver are volatilised, and the zinc remains in the residue.—T. H. Bu.

Cleaning and coating metal articles. N. Meurer. E.P. 154,235, 8.1.18.

THE articles are charged into a heat-insulated rotary drum, provided with apertures for removing the dust, and with inner projections adapted to lift the pieces under treatment and drop them through the drum space and then through the jet of coating metal which is introduced obliquely into the drum from one of the ends. A shaft arranged crosswise to the drum in front of the injection opening carries the metal-squirting apparatus and also a sand jet blowing apparatus, these two devices being interchangeable.—J. W. D.

Metals; Method of coating —— [with aluminium]. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 154,808, 31.12.19.

THE metal to be coated, *e.g.*, iron or copper, is pickled in acid, coated with tin in the presence of a flux, dipped in molten aluminium, then fired at about 800° C. in order to produce an alloy of aluminium with the original metal.—J. W. D.

Copper; Production of coatings of —— on iron. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 324,472, 26.6.17.

A SMALL quantity of gelatin, glue, or the like, is added to the copper-plating bath for the purpose of obtaining fine-grain deposits suitable for wire drawing.—L. A. C.

Detinning of tinned iron scrap. M. A. Adam, J. Stevenson, and A. T. Mabbitt. E.P. 154,242, 26.2.19.

THE tin is dissolved from the scrap by a strong solution of the chlorides of tin and iron, with or without a small percentage of hydrochloric acid, and the resulting solution is electrolysed, the speed of rotation of the cathode, the liquid flow, and the current density being so regulated that only a comparatively small amount of the total tin content is deposited from the solution and that the tin is deposited in non-coherent form. The solution is then used again for detinning.—J. W. D.

Detinning. W. C. Zacharias, Assr. to Steel Works Appliances Co. U.S.P. 1,362,381, 14.12.20. Appl., 16.8.19.

TIN-COATED articles are heated to a temperature at which the coating material becomes friable, and subjected while heated to such mechanical treatment as will effect disintegration and consequent detachment of the tin.—J. W. D.

Copper; Production of spring or tempered ——. S. O. Cowper-Coles. E.P. 154,373, 11.9 and 29.11.19.

COPPER is deposited electrolytically from a copper sulphate solution, to which an organic substance (*e.g.*, glue or gelatin) or arsenic is added from time to time, on to a cathode or mandrel revolving at a critical speed of not less than 1000 peripheral ft. per minute. The greater the speed the harder is the deposited copper. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 21,974 and 26,724 of 1898, 26,211 of 1906, 30,377 of 1909, 23,775 of 1912, and 104,678; J., 1899, 1132; 1907, 1286; 1911, 137; 1917, 1277.)—J. W. D.

Copper; Process of extracting —— from its ores. L. D. Mills, Assr. to The Merrill Co. U.S.P. 1,360,666, 30.11.20. Appl., 23.1.17.

IN a process of extracting copper, finely-divided freshly-reduced iron is employed to precipitate copper from its solution– A. de W.

Sulphide ores containing lead and zinc; Treatment of ——. P. A. Mackay. E.P. 154,718, 4.9.19.

FINELY-GROUND sulphide ore containing lead is subjected to the action of sulphuric acid containing free sulphur trioxide in solution, or to the action of sulphur trioxide gas or vapour, whereby the lead is converted into lead sulphate. No external heat is supplied, the action being exothermic. The lead sulphate is subsequently separated from the un-

altered zinc sulphide by known methods. Bismuth, cadmium, silver, or the like when present are also converted into sulphates.—J. W. D.

Mineral residues in a pulverulent condition; Conglomeration of ——. L. A. E. Irazusta. E.P. 155,522, 29.6.20.

PURE alumina and water are employed as binding agent in proportions varying according to the character of the mineral to be smelted, and the mixture is then formed into briquettes.—T. H. Bu.

Ore-separator; Magnetic ——. H. W. Arnold. U.S.P. 1,362,072, 14.12.20. Appl., 17.11.17.

A MAGNETIC drum carrying a number of magnets enclosed in a water-tight casing revolves in a trough with an adjustable inlet apron for introducing water and material. An outlet apron with an adjustable scraper is arranged at the opposite side of the trough, and tailings are removed from the bottom by means of an adjustable gate with an adjacent partition for separating the tailings from particles on which the magnetic attraction is only slight.—T. H. Bu.

Rust-proofing process. E. P. Andrews. U.S.P. 1,362,213, 14.12.20. Appl., 22.12.19.

THE articles to be treated are subjected to an oxidising atmosphere at about 650° C. to form a coating of magnetic oxide, which is fixed by dipping the articles in a liquid medium.—J W. D.

Ores; Process of treating —— *and apparatus therefor.* C. S. Fogh. U.S.P. 1,362,408, 14.12.20. Appl., 17.7.19.

IN the treatment of ore with a gaseous reagent, a moving body of ore is preheated, subdivided, and the portions are delivered at various points along the line of movement.—W. J. W.

Ore-reducing process and furnace. E. H. Hamilton. U.S.P. 1,362,570, 14.12.20. Appl., 2.7.19.

A BLAST of air and finely divided fuel is introduced into the charge at a point within the interior wall of the furnace. By this means escape of the fuel up the walls of the furnace is avoided.—T. H. Bu.

Electric induction furnaces [; Three phase ——]. Comp. Franç. des Métaux. E.P. 138,604, 20.1.20. Conv., 7.2.19.

AN induction furnace operating with three-phase current at 50 periods, and suitable for the fusion of metals and alloys, comprises three laminated cores each surrounded by a primary circuit. The primary circuits are surrounded by channels completely filled with metal, forming induction circuits and communicating with one another. Two of the channels are of different length from the third, which may be operated simultaneously with the others, or otherwise. The power factor is improved by flattening two of the channels in the form of horns. A cylindrical charging device closes from the air a chamber to receive the metal and communicating with the channels. A separate channel contains a resistor adapted to be heated by electric current.
—J. S. G. T.

Electric furnaces. L. Tagliaferri. E.P. 155,476, 2.2.20.

IN electric furnaces employing two- or three-phase current, in which the electrodes enter from both the top and sides of the furnace, the neutral wire is connected with a metal casing enclosing the furnace, whence the current is conveyed to one half of the electrodes by connecting leads.—J. S. G. T.

Electrical etching; Composition for electrolytes for ——. J. H. Weeks, Assr. to J. S. and R. M. Weeks. U.S.P. 1,362,159, 14.12.20. Appl., 4.4.17.

AN anode carrying a resistant image to be etched is employed in conjunction with an electrolyte compound of iron sulphate and a mineral acid.
—J. S. G. T.

Storage battery; Electric ——. *Electrolyte for electric storage batteries.* E. Hacking. U.S.P. (A) 1,362,294 and (B) 1,362,295, 14.12.20. Appl., (A) 17.12.19 and (B) 8.6.20.

(A) A SEPARATOR for electric storage batteries is formed by mixing an aqueous solution of sodium silicate and a solution of borax and sulphuric acid, with powdered pumice to the consistency of cream and allowing the mixture to solidify. (B) An electrolyte for storage batteries is composed of pumice and sulphuric acid.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Chaulmoogra oil; Fractionation of ——. A. L. Dean and R. Wrenshall. J. Amer. Chem. Soc., 1920, **42**, 2626—2645.

THE mixed fatty acids were distilled in 1-kg. portions from a 2-l. flask of the Claisen type, evacuated by a mechanical pump, and provided with a special receiver. The first 350 c.c. was worked up for hydnocarpic acid by fractional crystallisation from 80% alcohol and light petroleum, the next 300 c.c. was added to subsequent mixtures of crude acid, and the remaining distillate was treated for chaulmoogric acid by fractional crystallisation from 80% alcohol. The yields vary largely according to the quality of the oil, but even from low-grade oil 1 kg. of mixed acids yields at least 50 g. of pure hydnocarpic acid and 100 g. of pure chaulmoogric acid. (*Cf.* J.C.S., Feb.)—J. C. W.

Cantaloup seed oil. W. F. Baughman, D. Brauns, and G. S. Jamieson. J. Amer. Chem. Soc., 1920, **42**, 2398—2401.

CANTALOUP (*Cucumis melo, L.*) seeds were found to yield 30·4% of oil by extraction with ether. The cold-pressed oil had the following characters:—Sp. gr. at 25°/25° C., 0·9210; $n_D^{20}=1·4725$; iodine value (Hanus), 125·9; saponif. value, 192·3; Reichert-Meissl value, 0·33; Polenske value, 0·26; acetyl value, 15·8; acid value, 0·43; unsaponifiable matter, 1·1%; soluble acids, 0·4% (as butyric acid); insoluble acids, 94·0% unsaturated acids, 80·2%; saturated acids, 14·3%. The oil consisted of glycerides of myristic acid 0·3%, of palmitic acid 10·2%, of stearic acid 4·5%, of oleic acid 27·2%, and of linolic acid 56·6%; unsaponifiable matter, 1·1%. No film developed even after 1 week when the oil was exposed to the air on a glass plate.—W. G.

Catalytic activity of platinum [in hydrogenation]; Influence of lead on the ——. E. B. Maxted. Chem. Soc. Trans., 1920, **117**, 1501—1506.

THE influence of the addition of successive small increments of lead, which was chosen as a typical non-volatile catalyst poison, on the subsequent activity of finely-divided platinum as a hydrogenating catalyst was studied by measuring the velocity of the absorption of hydrogen by a given weight of oleic acid under standard conditions in presence of a fixed amount of the catalyst and varying proportions of lead acetate dissolved in acetic acid. The depression of the catalytic activity of the platinum due to increasing proportions of lead was found to follow a linear law analogous to that observed for the inhibition of occlusion (J., 1920, 782 A). The view is developed that a certain proportion of the catalyst is poisoned by each milligram of lead added, the remaining catalyst functioning normally. This involves the assumption that the initial velocity of absorption induced by varying weights of catalyst under otherwise identical conditions, varies directly with the weight of platinum available for hydrogenation. This was shown experimentally to be the case.—G. F. M.

[Cottonseed oil soapstock;] Application of super-centrifugal force [to recovery of oil from ——]. E. E. Ayres, jun. Chem. and Met. Eng., 1920, **23**, 1025—1026. (*Cf.* Menzies, J., 1920, 231 T.)

BY diluting soapstock, obtained as a by-product in cottonseed oil refining, until it is no longer gelatinous and then centrifuging it, a light emulsion and a heavy effluent are produced. The former contains oil globules of almost uniform size, 0·008 mm. diam., and closely packed together, whilst the latter comprises a few scattered globules, 0·002 mm. diam., By adding salt water to the light emulsion and re-centrifuging, a yield of about 60% of the oil in the soapstock may be recovered.—W. J. W.

Mustard seed and substitutes. I. Chinese colza (Brassica campestris chinoleifera Viehoever). A. Viehoever, J. F. Clevenger, and C. O. Ewing. J. Agric. Res., 1920, **20**, 117—140.

A BOTANICAL and chemical study of seeds imported as rape seed, sold as mustard seed, and identified as Chinese colza, *Brassica campestris chinoleifera*, Viehoever, n. var. The characteristics of the seeds have been established, and those which permit the identification and differentiation from true mustard seed are pointed out. The volatile oil from these seeds was identified as crotonyl isothiocyanate, an oil formerly found in rape, and not a suitable substitute for mustard oil in respect to condimental, bactericidal, or medicinal value. The yield varied from 0·4 to 0·6%, as compared with about 0·7—1·0% of volatile oil from true mustards, except *Sinapis alba*. The fixed or fatty oil expressed from the seed (yield 40—50%) showed the general characteristics of rape oil. It had sp. gr. 0·9097 at 25° C.; iodine value (Hanus), 100·3; saponif. value, 173·8; insoluble acids and unsaponifiable matter, 96·1%; soluble acids, 0·07%; $n_D^{25}=1·4695$, solid acids, 19·52%; liquid acids, 75·82%. From the general composition of the seed and the character of the volatile oil it is suggested that the pressed oilcake may well be used as a stock feed. The plants, which are very vigorous and apparently hardy, offer possibilities as a forage crop.—W. G.

Spermaceti and its examination for purity. P. Bohrisch and F. Kürschner. Pharm. Zentralh., 1920, **61**, 703—710, 719—726, 733—737.

STEARIC ACID, tallow, and paraffin, the usual adulterants of spermaceti, when present, alter the coarse leafy structure, rendering it small-leaved or granular, duller, and causing the spermaceti to lose its characteristic mother-of-pearl lustre. The sp. gr. of 21 samples of spermaceti obtained from wholesale and retail druggists in 1916 was determined; the values for trustworthy samples varied between 0·916 and 0·942, average 0·929. The determination of the sp. gr. does not, however, yield trustworthy results owing to the presence of air pockets in the sample as melted and cast for the determination. The limits of m.p. for the 21 samples examined were 44° C.—47·5° C. Spermaceti rapidly becomes rancid when exposed to light, but in metal or porcelain containers it may be kept for at least two years without becoming rancid. The so-called grease-spot test is of no value as a criterion of purity, since samples adulterated with 10% of stearic acid or tallow yield no grease spot when rubbed on paper. In the melted condition even the pure article greases paper. For the detection of paraffin in spermaceti the method of Branderhorst (Pharm.-Weekblad, 1909, 1043) is recommended. The sample (0·25 g.) is boiled with 5 c.c. of 10% potassium hydroxide solution in a test-tube, and 2—3 c.c. of cold distilled water is added. The presence of even 1% of paraffin is shown by the formation of an immediate clouding. Pure spermaceti also develops a cloudiness after one minute. For the detection of stearic acid Frerichs' modification of the ammonia test

(Apoth.-Zeit., 1916, 209) is best: 1 g. of spermaceti is warmed with 10 c.c. of ammonia in a test-tube until melted and is then thoroughly shaken. The cooled filtrate should show no separation on addition of dilute hydrochloric acid. The addition of acid may be omitted, as even in presence of 1% of stearic acid a cloudy filtrate is obtained. The acid and ester values of spermaceti are conveniently determined by a modification of von Hübl's method as follows: 3 g. of spermaceti is dissolved in 20 c.c. of light petroleum spirit in an Erlenmeyer flask, 5 c.c. of absolute alcohol added, and the mixture titrated with $N/2$ alcoholic potash until permanently red to phenolphthalein. This gives the acid value. A further 25 c.c. of $N/2$ alcoholic potash is added, the mixture carefully agitated, and allowed to stand in a stoppered vessel for 24 hrs. Titration with $N/2$ hydrochloric acid gives the ester value. Genuine spermaceti shows an acid value up to 2·0, and a saponification value of 118—135. The iodine value serves as a measure of the sperm oil contained in a sample of spermaceti, commercial samples of the latter giving iodine values of 3·0—5·0. The preparation known as "spermaceti sugar," used as a remedy against coughs and hoarseness, is best prepared by moistening a mixture of spermaceti and sugar with alcohol and evaporating the solvent. Its purity is tested by extraction of the spermaceti with ether, and determination of the acid and saponification values on the sugar-free sample.
—A. de W.

Soap solutions; Surface tension of certain ——, and their emulsifying powers. M. G. White and J. W. Marden. J. Phys. Chem., 1920, 24, 617—629.

THE cleansing power of soap is due to the fact that soap solutions have a low surface tension compared with that of pure water (but of approximately the same order as that of many oils) and not to the free alkali which is liberated by the soap when it is dissolved in water. Determinations of the surface tension of solutions of sodium stearate and sodium palmitate showed that this decreases with increasing concentration. The emulsifying power of solutions of sodium palmitate and sodium stearate for kerosene and linseed oil increases with increasing concentration of the soap solution, *i.e.*, as the surface tension increases, the emulsifying power decreases. The presence of glycerin does not affect the surface tension to a considerable extent, and, therefore, the presence of glycerin should have no deleterious effect on the cleansing power of soap. The presence of large amounts of sodium carbonate in soap is undesirable, because this raises the surface tension and reduces the cleansing power.
—J. C. K.

Sodium oleate solutions; Investigation of —— in the three physical states of curd, gel, and sol. M. E. Laing and J. W. McBain. Chem. Soc. Trans., 1920, 117, 1506—1528.

A SOAP solution of one and the same concentration at any definite temperature may be prepared in the three characteristic states of clear fluid sol, transparent elastic gel, and white opaque curd. The sol and gel forms are identical in osmotic activity, concentration of sodium ions, conductivity, and refractive index, and differ only through the mechanical rigidity and elasticity of the gel. This proves that identical chemical equilibria and constituents are present in the two cases. The quantitative identity of conductivity in sol and gel is irreconcilable with all theories of gel structure hitherto advanced except the micellar theory of Nägeli. The formation of soap curd is analogous to a process of crystallisation, neutral soap separating from the solution in the form of curd fibres of microscopic or ultramicroscopic diameter. Coagulation and crystallisation are thus sharply distinguished from gelatinisation. The curd fibres consist of hydrated neutral soap, the hydration depending on the origin and previous history. Within corresponding limits their solubility is definite for each temperature, the so-called melting points being the temperatures at which the solubility curve rises to a value equal to that of the total concentration of the soap, and at which the last curd fibre just dissolves. The above results are of general applicability. A transparent commercial soap is a gel, all other hard soaps being gels containing a felt of curd fibres.—G. F. M.

PATENTS.

Hydrogenation of unsaturated organic compounds [fatty acids and fatty acid esters]; Catalysts for use in ——. De Nordiske Fabriker De-no-fa Aktieselskap. E.P. 140,371, 13.1.20. Conv., 17.3.19.

CATALYSTS are prepared by precipitating aluminates of heavy metals, especially nickel aluminate, with a soluble aluminate, *e.g.*, sodium aluminate, the heavy metal aluminate being then washed, dried, and reduced in a current of hydrogen at 300°—400° C. Alternatively nickel aluminate may be precipitated on an inert carrier, *e.g.*, kieselguhr, and subsequently reduced.—A. de W.

Oils and fats; Method of refining —— whereby they are deodorised and their acidity is reduced. K. H. Vakil. E.P. 155,020. 9.9.19.

A VEGETABLE, fish, or animal oil or fat is heated to 220°—300° C., and then brought into intimate contact with a current of carbon dioxide or a mixture of carbon dioxide and nitrogen, which may be at ordinary or higher temperature. For example, on heating coconut oil to 250° C. and passing carbon dioxide through it for 2 hrs., the acidity is reduced from 5·4% to 0·58% and the odour is completely removed.—A. de W.

Soap and detergent; Process of making ——. M. Aisen, Assr. to Grain Soaps Corp. U.S.P. (A) 1,360,252, (B) 1,360,253, and (C) 1,360,254, 30.11.20. Appl., (A) 20.11.19, (B) 30.9.20, (C) 7.10.20.

(A) CEREALS are hydrolysed by subjecting them for 2 hrs, to a high temperature, below that of carbonisation (180° C.), anhydrous sodium carbonate or equivalent alkali carbonate in the proportion of 1 pt. to 2½ pts. of cereal is added, one-seventh by weight of caustic soda dissolved in water is sprayed into the mixture, and the mass is heated to the melting-point of the sodium carbonate crystals (below 100° C.) and maintained thereat for 1 hr. to effect saponification, after which any excess of sodium carbonate and caustic soda is neutralised with a fatty acid. (B) To the hydrolysed cereals from the heat treatment described above are added 1 pt. of a fatty acid to 1¾ pts. of cereal, and caustic soda dissolved in water in the proportion of 1 pt. of caustic soda to 5 pts. of cereal. (C) A cereal flour is hydrolysed by means of a mineral acid and heat, the hydrolysed mass saponified by an alkali, and any free alkali then neutralised with a fatty acid.
—A. de W.

Saponaceous cleansing composition; Method of manufacturing a ——. R. Gans. E.P. 132,511, 8.9.19. Conv., 24.6.18.

SEE G.P. 313,526 of 1918; J., 1920, 121A.

Fatty acids from paraffin. E.P. 142,507. *See* IIA.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Prussian blue; Decolorisation of —— by oxidised oils. F. Fritz. Chem. Umschau, 1920, 27, 242—243.

ON cutting a section through a piece of blue or green linoleum, a banded structure can be fre-

quently observed, the face and back layers retaining their original colour, whilst the middle layer has changed to brown. On exposing the brown layer to air or, better, to air and light, the original blue colour is restored. The loss of colour is ascribed to the reduction of the Prussian blue to ferrous ferrocyanide, $Fe_2Fe(CN)_6$, by the oxidised linseed oil. If a small quantity of Prussian blue be allowed to stand for a long time in contact with oxidised linseed oil in a test-tube, with frequent shaking, decolorisation of the pigment takes place if a sufficient amount of moisture is present. The examination of a section of blue or green linoleum can serve for the determination of the degree to which air has penetrated.—A. de W.

PATENTS.

Lacquering; Process of ——. Soc. Anon. l'Hélice Intégrale, anc. Etabl. L. Chauvière. E.P. 118,610, 23.7.18. Conv., 30.8.17

In a process of lacquering on an industrial scale in climates unfavourable to the rapid progress of hardening, the lacquered articles are subjected in a dark chamber to the regulated action of heat, humidity, ozone, and electricity, the source of the latter two agents being disposed behind screens to protect the lacquered articles from the ultra-violet rays. In this way hardening of the lacquer is effected in a reasonably short time.—A. de W.

Japans [; Manufacture of black ——]. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 155,427, 5.11.19.

A NON-OLEAGINOUS protective colloid, *e.g.*, a solution of glue, starch, agar, or water-glass, is added to the "water-japan" described in E.P. 121,533 (J., 1919, 81 A), and which consists of an emulsion in an ammoniacal solution of a japan base consisting of asphaltic material and a drying oil; *e.g.*, to 5 galls. of japan base in 10 galls. of water containing 0·5 gall. of ammonia (sp. gr. 0·9) is added 10—20% by vol. of a 20% solution of glue. The colloid may be added before emulsification.—A. de W.

Phenolic bodies; Condensation of —— *with aldehydic compounds.* Vickers, Ltd., The Ioco Rubber and Waterproofing Co., Ltd., and W. H. Nuttall. E.P. 154,656, 29.7 and 15.12.19.

A METALLIC carbide, nitride, silicide, phosphide, or cyanamide is used as condensing agent and to remove part of the water resulting from the reaction between a phenol and an aldehydic compound. For example, a mixture of 30 lb. of phenol, 27 lb. of paraformaldehyde, and 5 lb. of calcium carbide is heated to 100° C. until a resin of the desired consistency is obtained, further heating producing an insoluble and infusible product. Such condensing agents may also be employed only for the completion of the reaction, in which case the lower layer resulting from the reaction between a phenol and an aldehydic substance in the presence of a catalyst is separated and mixed with the condensing agent; *e.g.*, 30 lb. of cresol, 30 lb. of 40% formalin, and 1 lb. of ammonium chloride are heated together in the usual manner, the lower layer separated, mixed with 4—8 oz. of powdered calcium carbide and warmed to 40°—50° C. until the heat of reaction is sufficient to complete the condensation.—A. de W.

Varnish and other ingredients; Recovery of —— *from waste micanite and the like.* H. C. S. de Whalley, and The Micanite and Insulators Co., Ltd. E.P. 155,318, 5.7.19.

WASTE micanite, or other material in the form of sheets of insulating material united together by varnish under pressure, is heated in a dilute aqueous solution of ammonia or other alkali or salts of alkaline reaction, such as borax, by means of steam at 4—6 atm. pressure, whereby the varnish is softened and the solvent penetrates between the surfaces of the sheets. Alternatively, the micanite may be treated with water in place of ammonia or other solvent, and the hot, wet material stirred into the cold alkaline solution. The resins are recovered from the alkaline solution after straining and, if desired after concentrating the same, by neutralising with sulphuric acid or the like, and heating the solution to facilitate the formation of a clot of melted resin which is then purified by remelting and washing.—A. de W.

Painting, priming, and like compositions [emulsion paints]; Manufacture of ——. E. Schou, and Emulsion A./S. E.P. 155,398, 30.9.19.

AN "oleaginous material," *e.g.*, 40 pts. of a drying oil, oil varnish, lacquer, resin or wax solution, etc., is emulsified in a suitable emulsifying agent, *e.g.*, a thin aqueous solution or very fine mixture of 2 pts. of starch, casein, glue, etc. with 58 pts. of water, in homogenising apparatus of the type described in E.P. 140,147 (J., 1920, 377 A), or in other suitable apparatus, whereby the oleaginous particles are reduced to a diameter of 10μ or less. Materials solid at ordinary temperatures are melted previous to emulsification. An increased "body" is obtained in the emulsified material by further addition of emulsifying ingredients, with or without the addition of suitable organic matter, or the emulsion may be concentrated by evaporation, osmosis, etc. of the water.—A. de W.

Linseed oil substitutes [for paints]; Preparation of ——. D. Schoonderwaldt. E.P. 155,508, 26.5.20.

CRUDE American petroleum, *e.g.*, fuel oil, 1 pt. by wt., is heated in an open cauldron and 1/25th pt. by wt. of methylated spirit, 1/10th pt. by wt. of lime from shells, and 1/10th pt. by wt. of fatty pipe-clay added. The mixture is boiled well for 2 hrs. with agitation, strained to remove coarse particles, and mixed with 1/10th pt. by wt. of stand oil.—A. de W.

Resin; Process of producing ——. S. P. Miller, Assr. to The Barrett Co. U.S.P. 1,360,665, 30.11.20. Appl., 8.3.20.

THE polymerisable constituents in naphtha are polymerised with a polymerising agent below 20° C. —A. de W.

Acid pots for making white lead. E.P. 155,373. *See* VIII.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc; Action of sulphuric acid on natural and artificial varieties of ——. F. Kirchhof. Kolloid-Zeits., 1920, 27, 311—315.

COLD concentrated sulphuric acid converts raw rubber immediately into a hard, brittle mass which after several days becomes soft again. The action is accompanied by the evolution of sulphur dioxide, and the soft product becomes hard again when treated with water. Benzene solutions of raw rubber, gutta-percha, and artificial dimethyl-caoutchouc H, yield white solid substances which may be powdered and constitute oxidation products of the rubber. The action of sulphuric acid and the nature of the product are controlled by the nature of the solvent, by the quantity and particularly by the duration of the action of the acid, and by the concentration and nature of the rubber.—J. F. S.

Rubber; Regeneration of —— *in its technical and economic relations.* P. Alexander. Chem. Ind., 1920, 43, 531—537, 543—545.

THE method of regeneration should be selected to suit the crude material and the requirements of

the finished "reclaimed" rubber. The operation is essentially one of heat treatment for the restoration of plasticity, but the removal of fabric from the rubber scrap is commonly necessary, and for this purpose the so-called "acid," "alkali," "solution" and "mechanical" processes are available; of these the "alkali" method is most widely adopted, but the "solution" process possesses an advantage in that not only are both fabric and rubber recovered, but a partial separation of the compounding ingredients from the latter is also possible. For the evaluation of reclaimed rubber it is important that chemical examination should be supplemented by physical tests. The value of aniline in the "reclaiming" process is probably merely as a softening agent for the rubber, and not at all as a desulphurising agent. Regenerated rubber has nothing to fear from the competition of synthetic rubber, and in view of the probable increase in the demand for rubber goods the "reclaimed rubber" industry will be of importance in the future.—D. F. T.

PATENTS.

Rubber-proofed fabrics. L. Minton. E.P. 155,469, 20.1.20.

RUBBER-PROOFED fabrics with a lustrous finish are produced by applying mica powder to the adhesive rubber surface before vulcanisation, or by incorporating mica in the rubber before this is spread on the fabric.—D. F. T.

Rubber; Treatment of ——. Hunter Dry Kiln Co., Assees. of H. Hunter. E.P. 138,915, 11.2.20. Conv., 25.9.15.

XV.—LEATHER; BONE; HORN; GLUE.

Bating; Mechanism of ——. J. A. Wilson. J. Ind. Eng. Chem., 1920, **12**, 1087—1090.

THE mechanism of bating is shown to comprise reducing limed skins to a condition of minimum swelling, and digestion of the elastin fibres present in the outer layers of the skins.—W. P. S.

Tannin of oak bark. K. Feist and R. Schön. Arch. Pharm., 1920, **258**, 317—318.

THIS tannin contains no methoxyl group, but is converted by diazomethane into a stable methyl derivative, which has $[\alpha]_D^{15} = -43°$ and molecular weight ca. 1800. A precursor of the tannin could not be discovered in the bark, but a preparation of catechin—which gives the same degradation products—was also found to be lævo-rotatory. (*Cf.* J.C.S., Feb.)—J. K.

PATENTS.

Hides or skins; Curing ——. G. R. Olliphant. U.S.P. 1,362,502, 14.12.20. Appl., 6.4.20.

THE hides are soaked in an aqueous solution containing the leached constituents of "acid iron earth."—L. A. C.

Refuse from tanneries and the like; Treatment of ——. H. C. Marris, and W. Walker and Sons, Ltd. E.P. 154,961, 1.8.19.

A MIXTURE containing ferric oxide or hydroxide prepared by treating spent vegetable matter (tan bark etc.) from tanneries or sawdust with a solution of an iron salt, *e.g.*, iron chloride or sulphate, and spent lime liquor, is suitable for absorbing sulphur compounds from coal gas or the like.—L. A. C.

XVI.—SOILS; FERTILISERS.

Soil air; Carbon dioxide of the ——. H. W. Turpin. Cornell Univ. Agric. Exp. Stat., Memoir 32, Apr., 1920, 319—362.

EXPERIMENTS with oat and millet plants showed that the plant itself, and soil organisms, produce most of the carbon dioxide in the soil; at the period of its most active growth the plant often produces many times as much carbon dioxide as is produced by the soil organisms. There is little relationship between temperature and carbon dioxide content of a soil bearing crops, but with bare soil the carbon dioxide content is usually high during warm weather. The excess carbon dioxide in a soil growing a crop is due to respiratory activity of the plants rather than to decay of root particles. —W. P. S.

Plants; Influence of the lime-magnesia ratio on the growth of ——. O. Loew. J. Landw., 1920, **68**, 225—233.

ALTHOUGH there is some evidence that a lime-magnesia ratio of 1:1 or of 2:1, according to the nature of the soil, is the most favourable for the growth of plants (wheat and oats), pot cultures tend to give misleading results owing to crowding of the plants, interference with root growth, etc. —W. P. S.

Plants; Action of soda in the presence of potash as a food for ——. T. Pfeiffer, A. Rippel, and C. Pfotenhauer. J. Landw., 1920, **68**, 255—284.

SODIUM salts may to some extent replace potassium salts as food for plants (cereals), and sodium is then found in the leaves and stalks.—W. P. S.

Carbon dioxide; Assimilation of —— *by green plants.* P. Mazé. Comptes rend., 1920, **171**, 1391—1393.

LEAVES were collected from a number of different species of trees and plants under the most varied atmospheric conditions and immediately distilled, without the addition of water, under reduced pressure at 60° C. In almost every case the distillate contained ethyl alcohol, acetaldehyde, and nitrous acid, but formaldehyde was never detected. In addition the leaves of maize and kidney beans, collected in very fine weather, gave acetylmethylcarbinol, elder leaves gave free hydrocyanic acid and glycollic aldehyde, and poplar leaves gave lactaldehyde and a substance which on oxidation yielded propionic acid. (*Cf.* J.C.S., Feb.)—W. G.

Dicyanodiamide; Direct method for the determination of —— *in [calcium] cyanamide and mixed fertilisers.* R. N. Harger. J. Ind. Eng. Chem., 1920, **12**, 1107—1111.

DICYANODIAMIDE is precipitated completely when its aqueous solution is treated with silver picrate; cyanamide and urea do not yield a precipitate with the reagent, and do not interfere with the determination of the dicyanodiamide. To determine dicyanodiamide in commercial calcium cyanamide, 10 g. of the sample is shaken for 30 mins. with 300 c.c. of water, then rendered slightly acid with nitric acid (litmus indicator), 75 c.c. of 5% silver nitrate solution is added, the mixture diluted to 500 c.c., and filtered; 100 c.c. of the filtrate is treated with 15 c.c. of 5% silver nitrate solution and 100 c.c. of saturated picric acid solution, cooled in ice-water for 30 mins., the crystalline precipitate

collected on a weighed asbestos filter, washed with water saturated with the crystalline compound (*e.g.*, a precipitate from a previous determination), afterwards with ether, dried at 100° C., and weighed. To the weight is added 0·0044 g. for each 100 c.c. of solution from which the crystals were filtered, and the result is divided by 5 to obtain the amount of dicyanodiamide present. In the case of mixed fertilisers, 20 g. is mixed with 50 c.c. of water, 100 c.c. of saturated barium nitrate solution is added, the mixture rendered alkaline with barium hydroxide solution, shaken for 30 mins., diluted to 500 c.c., and filtered; 100 c.c. of the filtrate is then treated as described. If the sample contains chloride, the mixture should be filtered after the addition of silver nitrate and before the picric acid solution is added.—W. P. S.

[Calcium] cyanamide; Changes taking place in —— when mixed with fertilising materials. R. N. Harger. J. Ind. Eng. Chem., 1920, **12**, 1111—1116.

WHEN calcium cyanamide is mixed with fertilisers containing acid phosphate (superphosphate) and 5—10% of moisture, the cyanamide content decreases rapidly, dicyanodiamide being the chief product of the decomposition; calcium cyanamide is not, however, affected by dry superphosphate. Moisture alone is capable of decomposing calcium cyanamide slowly.—W. P. S.

Bacterial decomposition of cellulose. Groenewege. *See* V.

PATENTS.

Fertiliser, and process for making the same. P. C. Hoffmann, Assr. to Virginia-Carolina Chemical Co. U.S.P. (A) 1,360,401 and (B) 1,360,402, 30.11.20. Appl., 19.6 and 10.8.20.

A FERTILISER is prepared by treating calcium cyanamide with (A) concentrated or (B) dilute phosphoric acid.—W. J. W.

Peat; Treatment of —— for making useful products. W. B. Bottomley. U.S.P. 1,355,732, 12.10.20. Appl., 19.5.19.

SEE E.P. 124,629 of 1918; J., 1919, 381 A.

XVII.—SUGARS; STARCHES; GUMS.

Sugars; Changes in the polarising value of —— during refining. A. F. Blake. J. Ind. Eng. Chem., 1920, **12**, 1104—1107.

THE changes which occur in the relationship between polarisation, true sucrose, and invert sugar during the refining of raw sugar are due in part to the destruction of lævulose by the action of heat and lime, and to the absorption of lævulose in excess of dextrose by the bone-black.—W. P. S.

Glucose [dextrose]; Disodium phosphate as catalyst for quantitative oxidation of —— with hydrogen peroxide. E. J. Witzemann. J. Biol. Chem., 1920, **45**, 1—22.

THE oxidation of dextrose by hydrogen peroxide is accelerated by the presence of disodium phosphate. The product of oxidation is carbon dioxide, and the reaction is catalytic and quantitative.—J. C. D.

Inulin; Relationship of —— to fructose [lævulose]. Constitution of polysaccharides. I. J. C. Irvine and E. S. Steele. Chem. Soc. Trans., 1920, **117**, 1474—1489.

INULIN yielded a dimethyl ether on treatment in sodium hydroxide solution with dimethyl sulphate. This was converted by further methylation with methyl iodide and silver oxide into trimethylinulin, a colourless viscous syrup, soluble in organic solvents, which represents the limit of methylation of inulin, showing that the latter contains three hydroxyl groups in each $C_6H_{10}O_5$ unit. On hydrolysis with 1% oxalic acid at 100° C. trimethylinulin is converted into a trimethylfructose belonging to the γ-series. For purposes of identification this was converted by way of its methylfructoside into tetramethyl-γ-fructose which proved to be identical with the tetramethylfructose obtained previously by the hydrolysis of octamethylsucrose. The structural relationship between sucrose and inulin is therefore a close one. From the uniformity of the products formed in the above reactions it appears that inulin is an aggregate of γ-fructose residues, each ketone molecule having lost two hydroxyl groups in the formation of the polysaccharide.—G. F. M.

Erythrodextrin; Individuality of ——. J. C. Blake. J. Amer. Chem. Soc., 1920, **42**, 2673—2678.

DEXTRINS which give deep-red colours with excess of iodine-water, preceded by little or no blue colour, that is, specimens which are comparatively poor in amylodextrin, are the best as sources of erythrodextrin. After precipitating amylodextrin from the solutions by means of dilute alcohol, the erythrodextrin fraction is separated as a heavy liquid by adding more alcohol. This is treated with ammonium sulphate, when the erythrodextrin separates in a high degree of purity and in a form which is easily desiccated. The chief impurity which is thus removed is amylocellulose. (*Cf.* J.C.S., Feb.)—J. C. W.

Conversion of cellulose into dextrose. Irvine and Soutar. *See* V.

Carbohydrates of the pecan. Friedemann. *See* XIXA.

PATENT.

Beet-molasses; Process of purifying ——. W. D. Bonner. U.S.P. 1,362,078, 14.12.20. Appl., 12.10.17.

SUFFICIENT tartaric acid is added to the diluted molasses to precipitate the bulk of the potassium as acid potassium tartrate, and, after separation of the precipitate, the purification is completed by evaporation of the solution.—L. A. C.

XVIII.—FERMENTATION INDUSTRIES.

Alcoholic fermentation; Chemically defined catalysts in ——. C. Neuberg and M. Sandberg. Biochem. Zeits., 1920, **109**, 291—329.

FERMENTABLE sugars, carbonyl acids of the carbohydrate series, aldehydic and ketonic plant bases, quinone and natural dyes, nitro and nitroso compounds, hydroxylamine derivatives, organic and mineral disulphides, polysulphides, thio and selenous acids, reducible metallic salts, and elements were investigated in regard to their effect on alcoholic fermentation.—S. S. Z.

Bacterial decomposition of cellulose. Groenewege. *See* V.

Alcohols. Macht. *See* XX.

PATENT.

Yeast and like substances; Air-pressure filtering apparatus for pressing ——. F. W. Littleton. E.P. 155,738, 1.4.20.

XIXA.—FOODS.

Milk; Influence of the diet of the cow upon the nutritive and anti-scorbutic properties of cow's ——. Vitamin studies. R. A. Dutcher, C. H. Eckles, C. D. Dahle, S. W. Mead, and O. G. Schaefer. J. Biol. Chem., 1920, **45**, 119—132.

THE vitamin content of cow's milk is dependent upon the vitamin content of the cow's ration. The anti-scorbutic value of summer milk was found to be superior to that of winter milk.—J. C. D.

Milk; Relation of fodder to the anti-scorbutic potency and salt content of ——. A. F. Hess, L. J. Unger, and G. C. Supplee. J. Biol. Chem., 1920, **45**, 229—235.

THE anti-scorbutic value of the milk and the percentage of certain inorganic and organic constituents may be influenced very greatly by the diet of the cow.—J. C. D.

Milk; Comparison of some methods for determining the fat content of skimmed ——. T. J. McInerney and H. C. Troy. Cornell Univ. Agric. Exp. Stat., Bull. 401, Jan., 1920, 69—85.

THE Adams gravimetric method, the Röse-Gottlieb method, and the Mojonnier modification of the same yielded concordant and trustworthy results, as did also the Babcock method when modified as follows: At least 25 c.c. of sulphuric acid should be used, the temperature of the testing machine should be at least 180° F. (82° C.), the centrifuge disc should have a diameter of 15 in. and a speed of 1800 revs. per min., and the test should be centrifuged for 10, 2, and 1 min. periods.—W. P. S.

Butter; Lecithin content of —— and its possible relationship to the fishy flavour. G. C. Supplee. Cornell Univ. Agric. Exp. Stat., Memoir 29, Sept., 1919, 101—151.

THERE is in normal butter a sufficient amount (0·04—0·07%) of lecithin to yield, on decomposition, small quantities of trimethylamine, and this substance is essential for the manifestation of a fishy odour.—W. P. S.

Butter; Phosphorus in ——. J. T. Cusick. Cornell Univ. Agric. Exp. Stat., Memoir 30, Apr., 1920, 159—187.

DURING churning, about 25% of the total phosphorus present in the cream is retained in the butter, the remainder passing into the buttermilk, washings, etc. Butters prepared by the author contained 0·025—0·041% of P_2O_5. In storage the soluble organic phosphorus compounds break down, yielding inorganic phosphorus compounds. This change is to some extent controlled by the treatment of the milk and cream before churning, but, under certain conditions, bacterial action is the chief cause of the change. Salt has a marked effect in promoting protein decomposition in butter during storage. The new alcohol-soluble protein found by Osborne and Wakeman (J., 1918, 220 A) in milk is also present in butter. Decomposition of lecithin with the formation of trimethylamine is the cause of fishy flavour in butter (*cf. supra*). When this fishy flavour develops there is always an appreciable loss of soluble organic phosphorus.—W. P. S.

Globulin of the cohune nut, Attalea cohune. C. O. Johns and C. E. F. Gersdorff. J. Biol. Chem., 1920, **45**, 57—67.

THIS globulin resembles that derived from the coconut (J., 1920, 169 A), and contains a relatively high percentage of arginine and histidine.—J. C. D.

Carbohydrates of the pecan. W. G. Friedemann. J. Amer. Chem. Soc., 1920, **42**, 2286—2288.

PECAN (*Carya olivaeformis*) kernels contained: Moisture 3·75%, ash 1·70%, crude protein 12·27%, crude fibre 1·71%, ether extract 69·76%, and nitrogen-free extractives 10·81%. The oil in the crushed kernels was completely removed by extraction with ether, and the carbohydrates were determined in the resulting meal. The results obtained, calculated as percentages on the moisture-free pecan kernel, were: Sucrose 1·18%, invert sugars 2·88%, araban 1·95%, methylpentosans 0·22%, cellulose (crude fibre) 1·76%, amyloid 0·59%, tannins 0·33%, hemicellulose etc. 4·09%. There was no indication of the presence of xylan, mannan, or starch. —W. G.

Humin formed by the acid hydrolysis of proteins. VI. Effect of acid hydrolysis upon tryptophan. G. E. Holm and R. A. Gortner. J. Amer. Chem. Soc., 1920, **42**, 2378—2385.

WHEN tryptophan is boiled with 20% hydrochloric acid it is slowly altered, and by prolonged hydrolysis parts of the molecule are broken down. In the absence of aldehydes or other reactive substances, tryptophan contributes but a very small fraction of its nitrogen to the "acid-insoluble" humin, but after boiling with acid for 144 hrs. a much larger amount of the tryptophan appears in the "soluble humin." As a protein hydrolysis rarely requires more than 24 hrs.' boiling, it is very improbable that the "total" humin in the products of hydrolysis is derived from tryptophan without the intervention of some other reactive compound. Tryptophan is relatively easily deaminised by boiling with 20% hydrochloric acid, and probably some of the ammonia in the normal products of protein hydrolysis is derived from tryptophan. After hydrolysis of this amino-acid the distribution of the nitrogen is such that errors may be introduced into both the "basic" nitrogen and the "non-basic" nitrogen fractions of a Van Slyke determination (*cf.* J., 1911, 1135).—W. G.

Mustard seed and substitutes. Viehoever and others. *See* XII.

Phosphatides. Brauns and MacLaughlin. *See* XXIII.

PATENTS.

Coffee substitutes; Manufacture of —— from cereals and the malt of cereals. K. Lendrich. E.P. 131,304, 12.8.19. Conv., 28.4.17.

CEREALS or malted cereals are uniformly moistened with water, which may contain a small quantity of sodium or calcium chloride, and treated with steam at a continually increasing pressure and with agitation, until the starch, albumin, and cellulose have been rendered sufficiently and uniformly soluble. The product is then roasted.—J. H. J.

Grain; Apparatus for determining the amount of moisture in ——. J. S. Remington and J. P. Bennett. E.P. 154,315, 22.8.19.

GRAIN is fed through a spout on to the upper end of a shoot placed at such an inclination that the grain just slides down it. A weighted spring attached to the lower end of the shoot permits of slight variations in its inclination, such variations being indicated by a pointer on a scale or being recorded on a revolving drum. The angle of repose of grain increases with increasing moisture content. —J. H. J.

Fish and the like; Cooling and freezing of ——. J. J. Piqué, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 154,250, 28.5.19.

FISH are placed in wire baskets which are simul-

taneously rotated on their axes and circulated in the inner compartment of a tank of cooled brine. The baskets are each provided with an inclined baffle on opposite sides, so as to effect a shuffling of the fish as the basket rotates. The brine is cooled by evaporation surfaces placed underneath the inner compartment and is circulated by paddle wheels, passing through an immersed filter in the course of its circulation.—J. H. J.

Fish and the like; Cooling and freezing of ——. W. B. Hardy, J. J. Piqué, and The Imperial Trust for the Encouragement of Scientific and Industrial Research. E.P. 154,669, 22.8.19.

A TANK contains a horizontal cylindrical chamber, the top of which is in the form of a lid, through which fish or other articles are introduced. A central rotating shaft running through the chamber carries three blades reaching to the circumference. An opening covered with gauze runs along the side of the chamber for the introduction of the cooling liquid, and another opening is provided in the bottom for its exit. Valves are provided in the tank for adjusting the height of the cooling liquid. The lid of the chamber opens into a gutter into which the fish are floated for removal after being rotated in the chamber for a sufficient period to effect freezing.—J. H. J.

Food product and process for making same. R. De O. McDill. U.S.P. 1,361,079, 7.12.20. Appl., 2.3.20.

SUFFICIENT sugar to act as a sweetener and preservative is added to citrus fruit juice and the mixture is dehydrated below 175° F. (79° C.) to a heavy paste.—J. H. J.

Food products; Method of manufacturing ——. Food product and method of manufacturing the same. R. S. Fleming, Assr. to Merrell-Soule Co. U.S.P. 1,361,238 and 1,361,239, 7.12.20. Appl., 2.10.19.

A MIXTURE of fruit juice and a solution of glucose and dextrin produced by the hydrolysis of starch is atomised into a current of dry air, whereby the water is completely vaporised and the solids collect in the form of a dry powder.—J. H. J.

XIXB.—WATER PURIFICATION; SANITATION.

Water; Purification and sterilisation of —— by means of lime in connexion with the supply of drinking water in Netherlands E. Indies. J. Smit. Med. Geneesk. Lab. Weltevreden, 1920, 127—161.

A DARK brown moorland water on the east coast of Sumatra was treated with 1 g. of lime in the form of milk of lime per litre of water; after standing for 4 hrs. the number of bacteria was found to have been reduced to 40 per c.c., and after 10 hrs. to 6 per p.c. The water was neutralised by passing in carbon dioxide and then filtered. The filtrate was colourless and tasteless. In another water 0·1 g. of lime per litre was required to effect precipitation, leaving 0·084 g. per litre in solution, but the water was not sterile after standing for 24 hrs., and on further standing the alkalinity decreased and the bacteria increased. This result was due to the high temperature of the tropics. On infecting water with a culture of the cholera organism and treating with lime, no organisms were found in suspension at the end of 24 hrs., but the organisms in the precipitate were not all killed. Experiments were made to determine whether alum could be replaced by lime in the rapid filtration method of water purification. A turbid river water was mixed with 50—200 mg. of lime per litre and immediately filtered through ordinary laboratory filter paper under sterile conditions, giving a clear and alkaline filtrate. The first portion of this was rejected, and the subsequent portion collected separately and neutralised with carbon dioxide. The neutral filtrate was tested bacteriologically and found to be nearly sterile. The precipitate on the filter paper contained living bacteria. For more polluted waters quantities of lime up to 300 mg. per litre had to be used. Clear river water and distilled water were used also with the same results, so that the important factors were alkalinity and filtration. Pathogenic organisms added to water were removed in the same manner as ordinary organisms. The same results were obtained when the treated water was filtered through a layer of sand.—J. H. J.

Feed water for boilers; Purification of ——. G. Paris. Chim. et Ind., 1920, 4, 722—730.

THE continuous purification method, using sodium carbonate, with continuous removal of the precipitated calcium carbonate, is recommended. The method effects considerable saving in heat, amount of sodium carbonate required, supervision, etc., compared with other methods. Diagrams are given showing the application of the method. —W. P. S.

Water; Corrosive action of chlorine-treated ——. I. Effects of steel on the equilibrium $Cl_2+H_2O \rightleftharpoons HCl+HClO$, and of products of the equilibrium on steel. G. L. Clark and R. B. Iseley. J. Ind. Eng. Chem., 1920, 12, 1116—1122.

IN the presence of chlorine, the most active agent in rusting iron in water is hypochlorous acid, which disappears first from the solution. Rust is formed rapidly during the disappearance of the hypochlorous acid and practically ceases to form when the concentration of hydrochloric acid becomes constant; this indicates an equilibrium,

$$FeCl_3+3H_2O \rightleftharpoons Fe(OH)_3+3HCl.$$

The reaction $H_2O+Cl_2 \rightleftharpoons HOCl+HCl$ proceeds very slowly and comes to equilibrium; iron has an apparent catalytic action on this reaction, resulting in the disappearance of both chlorine and hypochlorous acid, but as the iron is present almost completely as ferric ion its action must be almost entirely chemical and not catalytic, since the equilibrium is entirely destroyed.—W. P. S.

Water analysis; Turbidity standard of ——. P. V. Wells. U.S. Bureau of Standards, Sci. Paper No. 367, 1920.

THE standard of turbidity adopted by the U.S. Geological Survey is shown to be inaccurate; this standard is a water containing 100 pts. per million of silica in such a state of fineness that a bright platinum wire of 1 mm. diam. can just be seen when 100 mm. below the surface of the water. The variations from the average may, in some cases, amount to 50%; this error could be eliminated largely by having all the standards prepared and distributed by some central authority.—W. P. S.

Active carbonic acid in drinking water; Calculation and determination of ——. I. M. Kolthoff. Chem. Weekblad, 1920, 17, 390—396.

FROM a review of the available data, assuming dissolved calcium carbonate to be completely dissociated, and the hydrolysis of carbonate to bicarbonate only to influence the results, the values $[OH']=7{\cdot}7\times10^{-6}$ and $p_{OH}=5{\cdot}11$ at 16° C. were calculated, this result indicating that the dissolved carbonate is hydrolysed to the extent of 57%. Estimation of p_{OH} in a solution of pure carbonate confirmed these figures. On boiling, the bicarbonate formed by hydrolysis loses carbon dioxide, hydroxide being formed; after boiling for

½ hr., the hydroxyl ion concentration was found to have increased tenfold, the new value being $7 \cdot 7 \times 10^{-5}$. A series of measurements of the solubility of powdered marble for various concentrations of carbon dioxide was carried out, carbon dioxide and bicarbonate being determined in the solutions after equilibrium was reached. The figures agreed fairly with the calculated, but were considerably lower than those determined from the table of Tillmans and Heublein. A new table is given, from which the active CO_2 can be deduced, when HCO'_3, CO_2, and $[Ca^{\cdot\cdot}]$ are known. The values of Tillmans and Heublein hold only where $[Ca^{\cdot\cdot}]$ is equivalent to $[HCO_3']$, which is only true for drinking water which has no permanent hardness. (*Cf.* J.C.S., 1921, ii., 59.)—S. I. L.

Active carbonic acid in drinking water. I. M. Kolthoff. Chem. Weekblad, 1920, 17, 558.

A reply to criticisms of the table put forward by the author (*cf. supra*). The values given in the table are stated to be not affected by the presence of such quantities of alkali or magnesium bicarbonates as would be found in drinking water, though if large quantities are present corrections must be made. The author's results are confirmed independently by Noll (J., 1920, 581 A), who also gives corrections for the presence of iron.—S. I. L.

Sewage; Purification of —— by the activated sludge process. L. Cavel. Comptes rend., 1920, 171, 1406—1407.

The author quotes experiments in support of his view that the purification of sewage by the activated sludge process is due to bacterial action. It is possible to shorten considerably the period of activation (normally 60 days). For example, by introducing some of the clinkers from a percolating bed, stopped seven months before, activation was accomplished in less than 15 days, and in one experiment in the laboratory the sludge was activated in 3 days.—W. G.

Phenol; Chemical potential of —— in solutions containing salts; and the toxicity of these solutions towards anthrax and staphylococcus. J. S. Laird. J. Phys. Chem., 1920, 24, 664—672. (*Cf.* J., 1920, 799 A).

The toxicity of a solution containing salt and phenol is the same as that of a solution containing phenol alone if the two solutions are in equilibrium with the same solution of phenol in kerosene. The use of this hydrocarbon offers the advantage over toluene that in the equilibrium experiments only a small proportion of the phenol passes into the upper layer. By the addition of salts the toxicity of a 4% phenol solution is altered owing to the change in the chemical potential of the phenol.
—J. C. K.

Germicidal value of some of the chlorine disinfectants. F. W. Tilley. J. Agric. Res., 1920, 20, 85—110.

Compared on a basis of weight of chloramine T (sodium toluene sulphone chloramide; Dakin, J., 1916, 651) as against weight of chlorine as sodium hypochlorite (Dakin's solution; *cf.* J., 1915, 919) or hypochlorous acid (eusol; *cf.* Rettie, J., 1918, 23 T), or as chlorine in aqueous solution, chloramine T is less efficient than the others. If, however, the comparison is made on the basis of "available chlorine" it is much more efficient against *Staphylococcus aureus*, much less efficient against *B. pyocyaneus*, and approximately equal in efficiency against *B. typhosus*. These chlorine disinfectants are apparently of little value against *B. tuberculosis*. Experiments upon anthrax spores indicate that the germicidal action of chlorine compounds is not always so speedy as is commonly supposed, but may extend over several days. The addition of ammonia to solutions of chlorine or hypochlorites very greatly increases their germicidal activity and tends to prevent depreciation in value on the addition of organic matter.—W. G.

Poisoning by nitrohalogen derivatives of methanes. A. Mayer, Plantefol, and F. Vlès. Comptes rend., 1920, 171, 1396—1397.

A description of the symptoms produced in the human organism when substances like chloropicrin, bromopicrin, or dichlorodinitromethane are inhaled or injected intraperitoneally. (*Cf.* J.C.S., Feb.)
—W. G.

Air contaminated with poisonous gases; Use of liquid sprays for purifying ——. A. Desgrez, H. Guillemard, and A. Savès. Chim. et Ind., 1920, 4, 814—817.

A fuller account of work, the chief results of which have been given previously (J., 1921, 59 A).

Bacterial decomposition of cellulose. Groenewege. *See* V.

Patents.

Waste organic substances; Process of and apparatus for treating ——. A. Maclachlan, Assr. to F. G. Reigart. U.S.P. 1,360,427, 30.11.20. Appl., 16.4.18.

Organic waste is placed in closed cylinders connected in series and is submitted to the action of an oxidising gas which is admitted to the first cylinder of the series below the level of the waste. The gas from the first cylinder is passed to the bottom of the second cylinder, and so on. Oily matter is precipitated upon the heavier oxidised waste.—J. H. J.

Sewage and like liquids; Separating and removing semi-solids from ——. S. H. Adams. E.P. 154,370, 11.9.19.

The crude sewage flows at a reduced speed over a perforated floor through which the sand and other heavy solids fall into a conical chamber below, where the solids pass directly into a displacement ejector worked by compressed air. The sewage passes on at an increased rate of flow to a second conical chamber into which it is directed in a downward direction, so that the flocculent matter and other solids fall to the bottom into an ejector, which is in the form of a continuous length of pipe, while the sewage flows upwards through a perforated screen in the upper portion of the chamber. Instead of using two chambers the whole operation may be conducted in one chamber, in which case the sewage passes downwards into the chamber and upwards through the perforated screen.—J. H. J.

Water softening. G. L. Borrowman. E.P. 155,092, 5.11.19.

See U.S.P. 1,348,977 of 1920; J., 1920, 671 A.

Clarifying liquids. E.P. 154,766. *See* I.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Cinchona series; Syntheses in the ——. VI. Aminoazo and hydroxyazo dyes derived from certain 5-amino cinchona alkaloids and their quinoline analogues. W. A. Jacobs and M. Heidelberger. J. Amer. Chem. Soc., 1920, 42, 2278—2286.

5-Aminodihydroquinine readily couples with diazotised aromatic amines to give crystalline azo dyes in which the amino group is remarkably labile. Most of these aminoazo dyes are red and give orange-red solutions in neutral solvents and deep purple solu-

tions in dilute acids. On boiling the solution in mineral acid the purple colour rapidly changes to brownish-red, the amino group being replaced by a hydroxyl group. Similar results were obtained with 5-aminodihydoquinidine and 5-aminoethyldihydrocupreine, amino-optochin). The lability of the amino group is apparently in part a function of the quinoline nucleus, as 5-aminoquinoline gives azo dyes which behave in a similar manner though somewhat less readily. The presence of a methoxy or ethoxy group in position 6 facilitates the replacement of the amino group.—W. G.

Codeine; Two new reduction products of ——. C. Mannich and H. Löwenheim. Arch. Pharm., 1920, **258**, 295—316.

Attempts were made so to modify the partially reduced benzene nucleus of morphine and codeine as to permit the normal application of the usual methods for determining constitution, since these give anomalous results when applied directly. Dehydroxydihydrocodeine, $C_{18}H_{23}O_2N$, m.p. 107° C., $[\alpha]_D = -81{\cdot}47°$, obtained as the chief product of reduction of β-chlorocodide in presence of palladium, behaves normally when subjected to degradation through exhaustive methylation, and gives dehydroxydihydrocodomethine, $C_{19}H_{25}O_2N$, m.p. 86° C., which in turn similarly yields 3-methoxy-5-vinyltetrahydrophenanthrylene oxide. Dehydroxytetrahydrocodeine, $C_{18}H_{25}ON_2, \frac{1}{2}H_2O$, m.p. 144°—145° C., $[\alpha]_D^{18} = -36{\cdot}92°$, is a secondary product of the above reduction and is also obtained by Clemensen's method (J., 1913, 711; 1914, 217) from dihydrocodeinone, $C_{18}H_{21}O_3N$, m.p. 193°—194° C., which is itself prepared by reducing codeine in presence of palladium. (*Cf.* J.C.S., Feb.)—J. K.

Angostura alkaloids. J. Troeger and K. Bönicke. Arch. Pharm., 1920, **258**, 250—277.

The existence of galipidine and cusparidine could not be confirmed by Troeger and Kroseberg (J., 1912, 1050), and it is now shown that the former is an impure form of galipine, and further that the formula of this base is $C_{20}H_{21}O_3N$. Like cusparin (Troeger and Müller, J., 1915, 449), it suffers demethylation when heated in dry hydrogen chloride, giving a phenol, $C_{17}H_{15}O_3N$, m.p. 225° C., and it is isomerised to isogalipine when gradually heated in a stream of methyl iodide vapour from 130° to 190°—200° C. (*Cf.* J.C.S., Feb.)—J. K.

Hyenanchin and other constituents of Hyenanche globosa. T. A. Henry. Chem. Soc. Trans., 1920, **117**, 1619—1625.

By extraction of the stems, leaves, and fruits of *Hyenanche globosa* (a South African plant of the order *Euphorbiaceæ*) with hot 95% alcohol, after removal of wax etc. by percolation with hot chloroform, a thick syrup was obtained, from which two crystalline isomeric toxic substances, of the probable formula, $C_{15}H_{18}O_7$, were isolated, to which the names hyenanchin and isohyenanchin are given. Hyenanchin is probably a dilactone, and is converted by the regulated action of weak alkali into a dihydroxydicarboxylic acid, $C_{15}H_{22}O_9$, which is unstable and readily loses a carboxyl group. It has a physiological action almost identical in kind with that of picrotoxin, but much weaker, and probably belongs to the same group of convulsant non-nitrogenous poisons as picrotoxinin and tutin. A new wax alcohol, $C_{24}H_{49}OH$, m.p. 82°—83° C. (corr.), and a new phytosterol, $C_{28}H_{46}O$, m.p. 265° C. (corr.), were isolated from the chloroform extract of the leaves and stems, and a yellow colouring matter of the flavone group from the ethereal extract of the tannin.—G. F. M.

Cocaine solutions; Influence of the reaction of —— *on their stability.* A. Rippel. Arch. Pharm., 1920, **258**, 287—295.

The activity of cocaine solutions of definite acidity or alkalinity after sterilisation by heat was determined by physiological tests. Boiling for one hour in neutral solution or in a solution of the same alkalinity as the blood caused diminutions in activity of 60—70% and 80% respectively, but no deterioration occurred in solutions varying in acidity from $p_H = 1$ to $p_H = 5{\cdot}8$. Similar, but less rapid, changes took place at the ordinary temperature. (*Cf.* J.C.S., Feb.)—J. K.

Santonin; New source of ——. H. G. Greenish and C. E. Pearson. Pharm. J., 1921, **106**, 2—3.

About 1% of santonin was found to be present in the leaves of *Artemisia brevifolia*, a plant growing abundantly in Cashmir and Western Thibet at an altitude of 9000—14,000 ft.—W. P. S.

Anti-body studies. III. Chemical nature of bacterial anti-bodies. F. M. Huntoon, P. Masucci, and E. Hannum. J. Amer. Chem. Soc., 1920, **42**, 2654—2661.

The anti-bodies of pneumococcus serum have been isolated as far as possible and the solution tested with protein reagents. It appears that they do not belong to the class of serum proteins. (*Cf.* J.C.S., Feb.)—J. C. W.

Arsphenamine (*3.3'-diamino-4.4'-dihydroxyarsenobenzene dihydrochloride*); *Hypophosphorous acid preparation of* ——. W. G. Christiansen. J. Amer. Chem. Soc., 1920, **42**, 2402—2405.

The reduction of 3-amino-4-hydroxyphenylarsinic acid gives a salvarsan (Fargher and Pyman, J., 1920, 465 A) which is relatively non-toxic. This furnishes a means of converting toxic arsphenamine (salvarsan) into a relatively non-toxic form by oxidation and subsequent reduction with hypophosphorous acid. Although the product obtained by this method is less readily soluble in water than that obtaind by the methyl alcohol-ether method, the use of warm water in dissolving it has not been found to be injurious. The source of the amino-hydroxyphenylarsinic acid does not affect the toxicity of the arsphenamine obtained from it.
—W. G.

Mercury derivatives of phthaleins. E. C. White. J. Amer. Chem. Soc., 1920, **42**, 2355—2366.

Mercury derivatives may be prepared from the phthaleins either by the action of yellow mercuric oxide on a solution of a phthalein salt or by the action of mercuric acetate on the free phthalein in alcoholic solution or aqueous suspension. Where an alcoholic solution is used in the second method an acetoxy-mercury derivative, $R.HgOOC.CH_3$, is formed. The mercury apparently enters the phenolic group of the phthalein molecule in the ortho position to the hydroxyl group or the quinone oxygen. The number of atoms of mercury entering the molecule is limited by the number of such free ortho positions, and if all four are occupied, as in Eosin, no substitution of mercury takes place. Mercury derivatives containing from one to four atoms of the metal have been prepared from the following phthaleins: phenolphthalein, *o*-cresolphthalein, fluorescein, dibromofluorescein, and phenolsulphonphthalein. In the determination of mercury in these compounds, the organic matter is destroyed by potassium permanganate and sulphuric acid and the mercury subsequently precipitated as sulphide and weighed. These compounds appear to be of some value in the treatment, both internally and externally, of genito-urinary infec-

tions and of syphilis. Identity of composition may or may not mean identity of biological behaviour if the two samples have not been made by precisely the same procedure.—W. G.

Mercury compounds of some phenylcarbinols. M. C. Hart and A. D. Hirschfelder. J. Amer. Chem. Soc., 1920, 42, 2678—2686.

Saligenin and *m*-nitro-*p*-hydroxyphenylcarbinol react with boiling mercuric acetate solution to form very insoluble mercury compounds of the formulæ

$$(HgOH)(CH_2OH)C_6H_3<\begin{matrix}O\\Hg\end{matrix} \quad \text{and}$$

$(HgOH)(CH_2OH)C_6H_2(NO_2)OH$ respectively. These yield insoluble salts with acids, but soluble salts with alkali hydroxides. They are about as powerfully antiseptic as mercuric chloride, but are far less irritant, and they are being used successfully in the treatment of gonorrhœa. (*Cf.* J.C.S., Feb.) —J. C. W.

Cyclohexane; Preparation of certain derivatives of ——. A. E. Osterberg and E. C. Kendall. J. Amer. Chem. Soc., 1920, 42, 2616—2626.

The preparation of cyclohexane derivatives on a large laboratory scale is described. Cyclohexane and cyclohexanol are obtained by reducing benzene and phenol by hydrogen under 115—120 atm. pressure in steel bombs at 250° C., the catalyst being nickel. Cyclohexanol is used as the source of cyclohexanone and cyclohexene. Cyclohexylamine is made from cyclohexanone-oxime, and 2-chlorocyclohexanol by the action of hypochlorous acid on cyclohexene. Chlorocyclohexanol is converted into aminocyclohexanol and this into 2-halogenocyclohexylamines. (*Cf.* J.C.S., Feb.).—J. C. W.

Dichloroacetic acid; Preparation of —— from chloral. G. W. Pucher. J. Amer. Chem. Soc., 1920, 42, 2251—2259.

Dichloroacetic acid may be prepared on a large scale by adding 400 g. of commercial sodium cyanide dissolved in 1100 c.c. of water to a solution of 1 kg. of chloral hydrate in 3 l. of water at 40° C., with constant stirring. The addition should be at such a rate that the temperature does not rise above 50° C. After one hour the water is evaporated off, the crude sodium salt is suspended in benzene, and dry hydrogen chloride is passed into the ice-cold suspension. The precipitated sodium chloride is filtered off and the dichloroacetic acid is recovered from the filtrate after distilling off the benzene. A yield of 60—65% of the calculated amount is obtained. Various metals were examined as to their resistance to corrosion by this acid. Aluminium appears to be the most resistant to the pure acid at 90° C., whereas the dilute acid attacks it readily, but does not attack copper or lead appreciably.—W. G.

Methylamines from methyl alcohol and ammonium chloride. W. D. Turner and A. M. Howald. J. Amer. Chem. Soc., 1920, 42, 2663—2665.

A mixture of ammonium chloride (1 mol.), zinc chloride (1·5), and methyl alcohol (12 mols.) heated at 303° C. for 8 hrs. in a steel tube gave yields of 55·0, 7·5, and 1·86% respectively of mono-, di-, and trimethylamines, calculated on the weight of ammonium chloride. A mere trace of amine is formed in the absence of a dehydrating agent. —J. C. W.

Ethyl iodide; Preparation of ——. B. E. Hunt. Chem. Soc. Trans., 1920, 117, 1592—1594.

The preparation of ethyl iodide is more successfully accomplished by using 80% instead of absolute alcohol, and the use of a large excess is unnecessary. The modified procedure is to add during the course of about 20 mins. 50 g. of red phosphorus to a mixture of 500 g. of iodine and 281 g. of 80% alcohol (by weight) in a 4 l. flask. The reaction mixture is then boiled gently for 2½ hrs. on a water bath, and the ethyl iodide thereupon distilled off, and purified in the usual way. The yield amounts to 92% of the theoretical. The main reaction appears to proceed according to Beilstein's interpretation with the formation of phosphoric acid, and not phosphorous acid as usually stated. The use of a few drops of thiosulphate solution in purifying ethyl iodide gives a product which darkens less rapidly than when sodium carbonate alone is used.—G. F. M.

Ether; Catalysis in the manufacture of ——. H. Schlatter. J. Ind. Eng. Chem., 1920, 12, 1101—1102.

The addition of aluminium sulphate offers no advantage in the manufacture of ether and is actually harmful since it causes pitting and rapid failure of the coils; the slight catalytic effect of the aluminium salt is not greater than that produced by the lead sulphate normally present in lead ether stills.—W. P. S.

Formaldehyde; Commercial ——. G. F. Merson. Pharm. J., 1921, 106, 4.

A supply of commercial formaldehyde solution received from the United States contained over 13% of proof spirit (ethyl alcohol); the use of ethyl alcohol in place of the usual methyl alcohol as a "filler" was evidently made for economic reasons. —W. P. S.

Alcohols; Toxicological study of ——. D. I. Macht. J. Pharm. Exp. Ther., 1920, 16, 1—10.

In the normal aliphatic series (methyl, ethyl, butyl, and amyl alcohols) the toxicity increases with the mol. wt. Secondary (propyl, butyl, and amyl) alcohols are less toxic than the corresponding primary alcohols.—J. C. D.

Thymol; Determination of —— in Spanish thyme oil. H. Mastbaum. Chem.-Zeit., 1921, 45, 18—19.

Spanish thyme oil is distilled from four varieties of thyme, but only one of the latter, *Corydothymus capitatus*, yields an oil containing a high percentage (67%) of total phenols; the oils obtained from common thymes, *T. vulgaris*, *T. Zygis*, and *T. hemalis*, contain about 35% of total phenols (thymol and carvacrol). The quantity of the latter may be determined by shaking the oil with 5% sodium hydroxide solution and measuring the volume of residual oil; the difference between this and the volume of oil taken gives the volume of the total phenols present. To determine thymol, 25 g. of the oil is shaken for 30 mins. with 100 c.c. of 5% sodium hydroxide solution, the alkaline solution is drawn off, and the extraction repeated with 80 c.c. and 50 c.c. of sodium hydroxide solution. The united alkaline extracts are diluted to 250 c.c., filtered, 200 c.c. of the filtrate is acidified with concentrated hydrochloric acid, and cooled in ice-water; the crystallised thymol is collected on a small suction filter, the oily portion (carvacrol) is drawn off as much as possible, and the crystalline mass pressed between filter paper and weighed.—W. P. S.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plate; Action of light on the ——. G. I. Higson. Phot. J., 1921, **61**, 35—44.

THE equations previously deduced by Slade and Higson (J., 1921, 27 A) are further examined in relation to the ordinary characteristic curve. General curves are deduced for the two equations for intensity scale exposures when I is large and when I is small, and also for the equation for time scale exposure when *t* is moderately large. These curves are similar to the characteristic curve, and a mathematical analysis of their properties leads to conclusions as to constancy of inertia, occurrence of under-exposure period, central speed method of plate testing, etc., which are in agreement with the results deduced directly from the characteristic curve. There is also a short examination of the problems which arise in passing from the case of a thin film of emulsion containing grains of uniform size and speed to ordinary emulsion films, several grains in thickness, the grains varying also both in size and speed.—B. V. S.

[Photographic] characteristic curve; Interpretation of a —— *with the aid of its first derivative.* F. F. Renwick. Phot. J., 1921, **61**, 10—12.

THE characteristic curve is obtained by plotting densities (D) against logarithms of exposures (log E). If instead of density the rate of increase of density ($dD/d \log E$) is plotted against log E, thus getting the first derivative of the characteristic curve, an ordinate of the new curve is proportional at any point to the amount of silver bromide rendered developable by the exposure at that point, but which is not developable at a smaller exposure. It is suggested that the use of these curves and a study of their meaning will assist materially in the solution of various photographic problems.
—B. V. S.

Soluble iodides; Action of —— *on photographic plates.* F. F. Renwick. Phot. J., 1921, 61, 12—15.

THE action on photographic plates of soluble iodides in sufficient quantity to convert all the silver bromide into iodide has been previously described (J., 1920, 156 T). Very weak solutions, however (1:50,000) produce a definite colour-sensitising which explains the supposed fogging action which had previously been ascribed to such solutions. Of other salts tested only cyanides, in strengths from 1:2000 to 1:10,000, behaved similarly. Spectrographs showing the added sensitiveness are given.
—B. V. S.

Sensitiveness of silver bromide; Reduction of —— *by amidol and allied bodies.* Lüppo-Cramer. Phot. Ind., 1920, 505—506.

USING 1/2000 solutions, amidol reduces the sensitiveness to 1/200, triaminotoluene to 1/600, triaminobenzene and triaminophenol to 1/60—1/70, diaminoresorcinol less still, and metol to 1/3. Plates bathed with erythrosin still retain some colour-sensitiveness after treatment with amidol, so that the method of development previously recommended, using a bright yellow light (J., 1921, 28 A), is not applicable to such plates.—B. V. S.

Sensitiveness of silver bromide; Action of developing solutions on ——. Lüppo-Cramer. Phot. Ind., 1920, 664—668.

ALKALINE solutions of quinol, metol, and edinol free from sulphite desensitise considerably, though less than amidol (*cf. supra*), pyrogallol solutions desensitise much less, and *p*-aminophenol, glycin, and catechol hardly at all. Plain aqueous solutions behave similarly if allowed to oxidise. Sulphite, in as low concentration as 3·5%, almost completely prevents the desensitising action, but the effect is only temporary, desensitising starting as soon as the oxidation of the sulphite allows formation of developer oxidation products. The effect is therefore due to interaction between the silver salt and the oxidation product. Quantitative measurements were made with quinol (*i.e.*, with its oxidation product, quinone), and with metol. The fact that strongly oxidised amidol solution is less effective than a fresh, slightly oxidised solution is explained as due to the existence in the former case of oxidised substance in colloidal condition and incapable of penetrating the film. The treatment with oxidised metol, and to a less extent with oxidised quinol, increased both the printing-out speed to daylight and the resulting density of the image. Quinone mixed with quinol has a stronger desensitising action than quinone alone, but mixed with quinol developer or metol-quinol developer green solutions are produced, and there is no desensitising.—B. V. S.

Negative development by candle light. Lüppo-Cramer. Der Photograph, 1920, 377—379.

A LARGE number of dyes have been examined as to their action on the sensitiveness of silver bromide, the most active in this respect being dyes of the Safranine class, particularly Phenosafranine, Tolusafranine, the diethyl- and tetramethyl derivatives of Safranine, and Brilliant Rhoduline Red. Developers containing 1/20,000 of Phenosafranine may be used for the development of plates by a bright yellow light, provided they are not exposed to it for the first minute; the process is applicable to colour-sensitised plates, which was not the case with the amidol process (J., 1921, 28 A). The effect is not due to the screening action of the dye solution, since not only is this too weak, but the plate may be lifted from the developer for examination by transmitted light in the usual way. Development is quite normal with metol, metol-quinol, rodinal, amidol, edinol, catechol, pyrogallol, glycin, and quinol, except that the last-named is rendered much more active. By increasing the strength of the dye solution to 1/2000 and using it as a separate bath before development, increased desensitising is obtained along with an added protection due to the staining of the film, and it is then possible to develop any plates, including panchromatic, by unscreened candle light; thorough washing is required to remove the dye from the stained film, assisted, if necessary, by treatment with an acid-alum bath containing 5% of hydrochloric acid and 2% of alum. A desensitising action has also been found with Methylene Blue, Auramine O, and Brilliant Green, but these dyes are not suitable for use on account of fog production or of interference with development. The amino groups of the Safranines appear to be necessary as the replacement of one of them by oxygen (in safraninone) considerably reduces the effect and the replacement of both by hydroxyl (in safranol) almost entirely destroys it.—B. V. S.

Ives' mordant dye-toning process; New bleach formulæ for the ——. F. E. Ives. Brit. J. Phot., 1921, **68**, Col. Supplement, 3.

IN the bleaching baths previously recommended (J.,

1919, 56A), containing chromic acid with or without potassium ferricyanide, it is an advantage to replace a proportion of the chromic acid by another acid, such as acetic, or by acetic acid and ammonium bichromate. The hardening action of the bath is reduced, and prolonged washing between bleaching and dyeing is avoided.—B. V. S.

Isocyanine dyes. Adams and Haller. *See* IV.

Dicyanine A. Mikeska and others. *See* IV.

Kryptocyanines. Adams and Haller. *See* IV.

PATENT.

Photo-sensitive silver compounds; Process of desensitising ——. N. Sulzberger. U.S.P. 1,361,352, 7.12.20. Appl., 10.12.14. Renewed 7.9.20.

LIGHT-SENSITIVE silver compounds, *e.g.*, in photographic films etc., are desensitised by treatment with a solution of ammonio-palladous chloride.
—B. V. S.

XXII.—EXPLOSIVES ; MATCHES.

Nitrations; Decomposition of nitric acid in organic ——. F. O. Rice. J. Amer. Chem. Soc., 1920, **42**, 2665—2670.

THE following results reproduce the mean of ten experiments on the nitration of phenol under ordinary conditions, varying from the small laboratory scale to a technical operation. The results are calculated on the basis of 100 g. of phenol, 260 g. HNO_3, and 427 g. H_2SO_4. Of the nitric acid 256·78 was ac-427 g. H_2SO_4. Of the nitric acid 256·78 g. was ac-in the vapours evolved from the nitrating vessel, 9·3 g. evolved as nitrogen peroxide, 17·3 g. as nitric oxide, 36·0 g. as nitrous oxide, 21·78 g. as nitrogen, and 4·6 g. in the spent acid. Of the phenol 94·9 g. was accounted for, viz., 79·2 g. in the picric acid, 5·2 g. oxidised to oxalic acid, 2·4 g. to carbon monoxide, and 8·1 g. to carbon dioxide. By keeping the temperature well below 100° C., especially at the commencement, reduction of the nitric acid to the lowest stages may be avoided, but some oxides of nitrogen are always produced. The best results are obtained by sulphonating almost to the disulphonate stage and then nitrating at about 30°—40° C. (*Cf.* J.C.S., Feb.)—J. C. W.

Explosives; Velocity of decomposition of high —— *in a vacuum. II. Trinitrophenylmethylnitroamine (tetryl).* R. C. Farmer. Chem. Soc. Trans., 1920, **117**, 1603—1614.

THE velocity of evolution of gas in a vacuum at 120° C. forms a useful method for the control of the stability of tetryl in the process of manufacture (*cf.* J., 1921, 63 A), samples of well purified material giving evolutions of 1·5—3·0 c.c. from 5 g. in 40 hrs. The reaction is very sensitive to catalytic influences, and probably one of the main causes of instability is the presence of analogues of tetryl containing a nitro group in the *meta*-position. Traces of picric acid may also be present, and this substance likewise greatly decreases the stability. The temperature coefficient of the decomposition of solid tetryl is 1·9 for 5° C. At the melting point (129° C.) an abrupt change in velocity occurs, the molten substance decomposing about 50 times as rapidly as the solid, and the acceleration in the decomposition at 120° C. is to a great extent due to progressive melting. For a similar reason admixtures which lower the melting point, such as trinitrobenzene or trinitrotoluene, also give rise to a rapid gas evolution. This does not indicate any chemical interaction, and at temperatures below the melting point of the eutectic mixtures the stability does not differ from that of tetryl alone.—G. F. M.

2.3.6.-Trinitrotoluene; Formation of —— *in the nitration of toluene.* R. B. Drew. Chem. Soc. Trans., 1920, **117**, 1615—1618.

THE products of the further nitration of both 2.3- and 3.6-dinitrotoluenes each contain about 15% of 2.3.6-trinitrotoluene, and on this basis it is calculated that crude trinitrotoluene obtained by the direct nitration of toluene contains about 0·3% of this isomeride in addition to the 2.4.6-, 2.3.4-, and 3.4.6-trinitrotoluenes already identified. 2.3.6-Trinitrotoluene was also synthesised from trinitro-*m*-cresol by reducing this with ammonium sulphide to 2.6-dinitro-4-amino-*m*-cresol (methylpicramic acid), eliminating the amino-group, converting the resulting dinitro-*m*-cresol into its methyl ether, replacing the methoxyl group by the amino-group by heating with alcoholic ammonia, and converting the resulting 2.6-dinitro-*m*-toluidine into 2.3.6-trinitrotoluene by Körner and Contardi's method (J., 1915, 1046).—G. F. M.

Explosives; Identification of —— *by determining their critical temperature of solution.* L. Crismer. Bull. Soc. Chim. Belg., 1920, **29**, 28—33. Chem. Zentr., 1920, **91**, IV., 695.

DETERMINATION of the critical temperature of solution provides a simple, rapid, and accurate method of identifying explosives. 2 g. of the substance is heated with 0·9—1·8 c.c. of 95% alcohol till dissolved, and the temperature at which separation occurs on cooling is noted. The critical temperature of solution of α-mononitronaphthalene is 44° C., and of trinitrotoluene, 96·5° C.—W. J. W.

Tetranitromethylaniline [tetryl]; Critical temperature of solution of ——. L. Crismer and J. Timmermans. Bull. Soc. Chim. Belg., 1920, **29**, 34—35. Chem. Zentr., 1920, **91**, IV., 695.

IN a German explosive the presence of tetranitromethylaniline was confirmed by a determination of its critical temperature of solution, which is 105° C.
—W. J. W.

PATENTS.

Detonating caps; Manufacture of ——. W. Friederich. E.P. 138,083, 19.1.20. Conv., 27.7.18.

THE composition for the caps consists of a nitro-compound, having above it a charge of lead azide, and above this a charge of lead trinitroresorcinate, either crystallised or dehydrated. Suitable compositions are: tetranitromethylaniline 0·9 g., lead azide 0·2 g., lead trinitroresorcinate 0·2 g.; or nitropentaerythritol 0·7 g., lead azide 0·2 g., lead trinitroresorcinate, 0·2 g. The use of lead trinitroresorcinate ensures a firm surface which will not crumble, and enables the charge to be more easily ignited.
—W. J. W.

(A) *Explosive.* (B, C) *Explosive mixture.* R. L. Hill, Assr. to Atlas Powder Co. U.S.P. (A) 1,360,397, (B) 1,360,398, and (C) 1,360,399, 30.11.20. Appl., (A, B) 25.7.19, (C) 30.8.18. All renewed 8.10.20.

AN explosive mixture consists essentially of (C) ammonium perchlorate and nitro-starch, to which (A) an oil, or (B) another diluent ingredient may be added.—W. J. W.

Smokeless powders; Manufacture of stable ——. C. Claessen. G.P. 298,567, 18.8.15.

NITROCELLULOSE is mixed with more than 21% of a eutectic mixture of solid trinitrotoluene and solid dinitrotoluene, or with complex combinations of these two substances, in presence of a volatile solvent.—W. J. W.

Explosives; Manufacture of ——. H. Lohmann. G.P. 298,948, 14.1.16.

METALLIC oxides and aluminium, in a fine state of

division and intimately mixed, are compressed, and can then be detonated by means of picric acid, mercury fulminate, dynamite, or guncotton.
—W. J. W.

Nitration acids from the manufacture of nitrocellulose or the like; Recovery of waste ——. S. Hamburger. G.P. (A) 300,758, 3.3.17, and (B) 300,747, 24.5.17.

(A) AFTER removal of the bulk of the waste acid in a centrifuge the residual acid in the nitrocellulose is displaced by spraying in sulphuric acid of approximately the same concentration as the waste acid so as to avoid rise of temperature. To reduce the evolution of nitrous vapours during the removal of the waste acid the centrifuge is run at half speed, but after the sulphuric acid treatment the maximum speed may be attained. (B) The process is similar to that described under (A), but the sulphuric acid is sprayed in at a stage when the nitrocellulose still retains a considerable quantity of nitration acid. (*Cf.* G.P. 299,680; J., 1921, 29 A.)
—W. J. W.

Explosive. R. Mewes. G.P. 302,493, 13.2.17. Addn. to 301,796 (J., 1920, 282 A).

As an absorbent for the compound of oxygen with nitrogen or chlorine, wood or straw, previously digested with alkali and then dried, may be used. Combustible liquids may be added.—W. J. W.

Drying Explosives; Process for ——. C. Gielow and A. Faust. G.P. 325,611, 14.5.18.

BY means of a conveyor the explosives are caused slowly to traverse a closed receptacle into which hot air is introduced by means of numerous inlets in the roof and sides. The exhaust air escapes at the rear of the receptacle into a filter where any suspended dust is trapped.—W. J. W.

Nitric esters; Method of washing ——. F. Hofwimmer. G.P. 325,944, 21.9.18.

AFTER the waste acid has been drawn off, the free acid retained in the nitrated material is neutralised with a saturated solution of an alkali carbonate, in such quantity as to form bicarbonate and avoid evolution of carbon dioxide. A saturated solution of a nitrate may be mixed with the carbonate solution in order to increase the volume of the wash-water and to reduce rise of temperature. The process is applicable to the purification of nitroglycerin and ethyleneglycol nitrate.—W. J. W.

Explosives; Manufacture of —— *in a form in which they can be cast.* Sprengstoff A.-G. Carbonit. G.P. 326,184, 7.8.17. Addn. to 307,040 (J., 1920, 282 A).

UREA alone, without a halogen salt, is heated with metallic nitrates or their mixtures. Suitable compositions consist of ammonium nitrate, 80%; sodium nitrate, 10%; urea, 10%; and ammonium nitrate, 90%; urea, 10%.—W. J. W.

Guncotton and the like; Apparatus for stabilising ——. H. Eicheler. G.P. 326,215, 5.10.17.

THE stabilising apparatus consists of an inner and an outer vessel separated from each other. The base of the inner receptacle in which the guncotton is placed is perforated, so that the washing liquid passes through the holes into the intermediate space, which serves as a heating vessel, and circulation of the washing liquid is effected.—W. J. W.

Illuminating grenade. J. Sonntag. G.P. (A) 300,760, 15.1.16, (B) 305,099, 15.7.16, and (C) 307,730, 24.4.17.

THE charge in an illuminating grenade consists of (A) magnesium, or (B) aluminium, strontium, barium, or calcium, or of mixtures of these with or without magnesium. The igniting mixture is composed of barium peroxide and granulated aluminium, or (C) other oxygen carrier mixed with granulated aluminium, magnesium, barium, strontium, or calcium, to which may be added sulphur and a carbonaceous substance, such as charcoal, lampblack, pitch, naphthalene, paraffin, or collodion.
—W. J. W.

Match-head composition, and method of making same. Composition for match-heads. W. A. Fairburn, Assr. to The Diamond Match Co. U.S.P. (A) 1,360,282 and (B) 1,360,283, 30.11.20. Appl., 12.8 and 6.10.15.

(A) A match composition contains a mixture of sodium chlorate and zinc dust. (B) A match-head composition contains a mixture of magnetic iron oxide and a metal of which the normal oxide has a greater heat of formation than magnetic iron oxide.
—W. J. W.

XXIII.—ANALYSIS.

Dialysis or extraction; Apparatus for continuous ——. H. Mann. J. Biol. Chem., 1920, 44, 207—209.

A DISTILLING flask and a dialysing or extracting vessel are connected by two sealed-in tubes; the upper tube is surrounded by a condenser and serves to supply fresh liquid for the operation, while excess liquid is continuously returned to the flask through the lower tube. A bag of collodion etc. is suspended in the dialysing vessel, and means are provided for connecting the apparatus with a vacuum pump.

Ultra-filters; Simple method of preparing ——. E. Knaffl-Lenz. Kolloid-Zeits., 1920, 27, 315—316.

AN ultra-filter for use with a Buchner funnel or a Gooch crucible may be prepared as follows:—A 3% solution of collodion is poured into a crystallising dish of the same internal diameter as the Buchner funnel, or into a porcelain crucible of the same internal diameter as the Gooch crucible, and is uniformly distributed by rotating the dish. As soon as the ether has evaporated the dish is filled with water three or four times, and finally the membrane is removed by loosening it at the edges and allowing water to flow between it and the glass. It is then placed in the Buchner funnel, which contains a filter paper, and carefully pressed to the sides of the funnel.—J. F. S.

Nephelometer; A new —— *and the principles of nephelometric measurement.* H. Kleinmann. Kolloid.-Zeits., 1920, 27, 236—241.

A NEW type of nephelometer is described, which depends on the measurement of the height of a Tyndall cone which produces the same intensity of illumination in two liquids, one of which is a standard. The apparatus consists of two glass tubes each graduated to a suitable volume, and containing the liquids for comparison. These tubes are placed side by side on a metal table before two shutters which may be opened to any measured amount. Into the glass tubes, two cylinders of polished glass just dip, and the light passing through these from the Tyndall cones illuminates the two halves of an optical system. The width of the shutter opening is then regulated until the two halves of the field are equally illuminated. The height of the Tyndall cone is controlled by the width of the opening of the shutters, and the intensity of illumination varies directly with the concentration. Experiments show that there is a strict proportionality between turbidity and concentration in the two tubes for the ratio 1:4 between the concentration in the two tubes. The instrument is easy

to operate, and amounts of phosphoric acid (P_2O_5) down to 0·0005 mg. in 25 c.c. of solution may be estimated with it (*cf.* J., 1920, 707 A) with an average error of 0·5%. An essential point is that the size of the particles in the turbid liquid is uniform. —J. F. S.

Gas analysis by absorption and titration. R. S. Tour. Chem. and Met. Eng., 1920, 23, 1104—1106.

For determining the volume of residual gas, after absorption of one constituent by a suitable reagent, a gas volume compensometer is employed. It comprises a gas flask, having a two-way tap at one end, by means of which communication may be established either with the absorption vessel or with one limb of a manometer. The other limb of the manometer is connected with the compensometer, which is a closed tube or bulb completely enclosed by the gas flask. At the end opposite to the two-way tap the flask is connected with a water reservoir. After filling the flask with water, the residual gas is drawn in by putting the flask in communication with the absorption vessel and running out water from the flask. The tap is then turned to connect the flask with the manometer, on the scale of which either the correction factor or the corrected volume (at 760 mm., 0° C., dry) may be read off. The percentage of the constituent, Y, in the original gas is determined from the formula $(100-Y)/Y=VJ/22{\cdot}4NQ$, where V=vol. of residual gas corrected to standard conditions, J=valency of absorbed constituent, N=normality of reagent, and Q=c.c. of reagent used for titration. The methods of calibrating the compensometer and of graduating the manometer scale are indicated, and a nomograph for the graphical solution of the above equation is described.—W. J. W.

Hydrogen ion concentration; Determination of the —— by means of indicators. L. Michaelis and A. Gyemant. Biochem. Zeits., 1920, 109, 165—210.

On adding a solution of a certain hydrogen ion concentration to an indicator a coloration of a definite depth is obtained, and by estimating colorimetrically the depth of the colour produced it is possible to determine the hydrogen ion concentration. The best conditions under which these estimations can be carried out are described, and the formula for calculating the results is given.—S. S. Z.

Barium and strontium; Volumetric determination of —— as chromates. I. M. Kolthoff. Pharm. Weekblad, 1920, 57, 972—979.

Barium and strontium respectively can be quantitatively precipitated as chromates by addition of bichromate under suitable conditions, and the excess of chromate may be estimated iodometrically in an aliquot part of the filtrate. Barium can be accurately determined in the presence of strontium or calcium, but strontium is not quantitatively precipitated as chromate from solutions containing barium or calcium. (*Cf.* J.C.S., 1921, ii., 62.) —S. I. L.

Nitrogen; Micro-determination of —— in agricultural materials. W. Geilmann. J. Landw., 1920, 68, 235—249.

A method for the determination of nitrogen in very small quantities of such substances as proteins, ammonium salts, etc., is described. It consists essentially of a micro-Kjeldahl digestion, the ammonia formed being distilled subsequently in a current of steam or removed by a current of air, absorbed in a definite quantity of standard acid, and the excess of this then titrated. Directions are given for the preparation of the reagents used, means for preventing atmospheric contamination, etc.—W. P. S.

Kjeldahl method for determining nitrogen; Investigation of the ——. I. K. Phelps and H. W. Daudt. J. Assoc. Off. Agric. Chem., 1920, 4, 72—76.

The results confirm those given previously (J., 1920, 351 A). Using the proportions given there, the 10 g. of potassium sulphate may be replaced by 8·2 g. of sodium sulphate. The influence of the reagents and the apparatus on the accuracy of the modified Kjeldahl process is indicated, and the desirability of control by blank experiments in routine work is emphasised.—W. G.

Kjeldahl method modified for nitrates; Use of permanganate in the ——. I. K. Phelps. J. Assoc. Off. Agric. Chem., 1920, 4, 69—71.

In the estimation of nitrates by the modified Kjeldahl method using a mixture of sulphuric acid and salicylic acid, the addition of potassium permanganate at the end of the boiling may cause the loss of nitrogen and it should therefore be omitted. —W. G.

Nitrogen determinations; Influence of potassium permanganate on Kjeldahl ——. D. C. Cochrane. J. Ind. Eng. Chem., 1920, 12, 1195—1196.

The addition of permanganate to the hot acid digestion mixture did not cause loss of nitrogen, provided that the addition was made within 2 mins. after cessation of boiling; the results obtained for feeding-stuffs and fæces are more concordant and uniformly higher when permanganate is used. —W. P. S.

Amino-nitrogen; Iodometric determination of —— in organic substances. H. H. Willard and W. E. Cake. J. Amer. Chem. Soc., 1920, 42, 2646—2650.

The Kjeldahl estimation can be shortened by cooling the mixture as soon as the organic matter is thoroughly charred, adding dry potassium persulphate, warming carefully until the liquid is colourless, which requires about 1 min., and then boiling to decompose the excess of persulphate. The solution is then cooled, rendered just alkaline, and the ammonia is estimated by adding an excess of standard hypobromite, leaving for a few minutes, then adding potassium iodide and hydrochloric acid and titrating with thiosulphate.—J. C. W.

Methoxyl group; Volumetric determination of the ——. J. Troeger and E. T. Tiebe. Arch. Pharm., 1920, 258, 277—287.

The quantitative demethylation of cusparine by dry hydrogen chloride (Troeger and Müller, J., 1915, 449) suggested the use of the method for the determination of methoxyl. Essentially the process consists in heating the material (0·1 g.) in a stream of dry hydrogen chloride, the temperature being gradually raised until bubbles of gas are seen to escape from the substance. The methyl chloride so produced is collected in a nitrometer over 30—35% sodium hydroxide solution. The results obtained in a number of cases were not absolutely accurate, but sufficed as a clear indication of the number of methoxyl groups present. The Zeisel method is not applicable to compounds containing sulphur, but the present method gave an approximate value in the case of galipinsulphonic acid, although not in another instance. (*Cf.* J.C.S., Feb.)—J. K.

Phosphatides; Quantitative determination of ——. D. H. Brauns and J. A. MacLaughlin. J. Amer. Chem. Soc., 1920, 42, 2238—2250.

Animal or vegetable tissues which cannot be reduced to powder, or solutions in volatile liquids, are dried on a water bath with a mixture of anhydrous sodium and calcium sulphates (*cf.* Robertson, J. Biol. Chem., 1916, 24, 409). The dry material is extracted

with absolute alcohol at 50°—60° C. in a Soxhlet apparatus. The extract is evaporated to dryness and extracted with dry ether. The ethereal extract is evaporated to 30—40 c.c., shaken with 15 c.c. of a saturated solution of sodium chloride, and then separated and evaporated to dryness and the residue weighed. In this residue the phosphorus is estimated colorimetrically by Van Eck's method (J., 1918, 559 A) by reduction with stannous chloride, the organic matter being first destroyed by Neumann's method of heating with sulphuric and nitric acids (Z. physiol. Chem., 1902, 37, 130). As a check on the phosphorus estimation, choline is estimated as its platinichloride after acid hydrolysis and amino-nitrogen is estimated by Van Slyke's method (*cf.* J., 1911, 771). From the results for choline and amino-nitrogen the ratio of lecithin to kephalin is established.—W. G.

Patents.

Calorimeters. Soc. des Hauts-Fourneaux de Rouen. E.P. 145,437, 18.6.20. Conv., 10.5.19.

The combustible fluid is supplied at a constant rate to a burner placed within a chamber having conducting walls, *e.g.*, a hollow thick-walled copper cylinder, surrounded by a jacket and provided with means for supplying primary and secondary air for combustion. Means are provided for measuring or recording the temperature of the walls of the chamber, which serves as a measure of the calorific value of the combustible fluid.—J. S. G. T.

Combustible gases; Method of and means for determining the calorific value of ——. Igranic Electric Co., Ltd. From The Cutler Hammer Manufacturing Co. E.P. 153,817, 4.2.20.

Gas and air are supplied to a mixing chamber in constant proportions by two wet displacement meters geared together and immersed in a tank so that the gases are under similar conditions of temperature, pressure, and saturation. The mixed gas passes to a burner enclosed in a tube closed at the top, so that the products of combustion are forced to travel downwards through this tube. The heat of combustion is absorbed by a stream of air which passes upwards through an outer concentric tube, the air being in a definite proportion determined by passing it through a third meter geared to the other two meters. If the proportions are kept constant, the temperature of the last-mentioned stream of air gives a measure of the calorific value of the gas. The readings are taken by electric resistance thermometers, and means are provided for compensating for variations of the calorific value due to dilution of the gas with water vapour, variations in the specific heat of the cooling gas with temperature, and incomplete transfer of heat to the cooling gas.—W. F. F.

Analysis of gases; Apparatus for the continuous ——. T. R. Wollaston. E.P. 153,637, 23.7.19.

A symmetrical double acting pump delivers the gas into two graduated vessels filled with inert liquid. The pipe connexions are such that an absorption vessel may be placed in circuit between the pump and either receiver, or omitted from both circuits. The liquid displaced from each receiver in a given period is continuously measured or weighed by a recording apparatus, and if one receiver includes the absorption vessel in its circuit while the other does not, the difference in the readings gives the amount of gas absorbed.—W. F. F.

Gas-analysing apparatus; Automatic ——. O. Rodhe, Assr. to Svenska Aktiebolaget Mono. U.S.P. 1,351,129, 31.8.20. Appl., 26.1.20.

An automatic gas-analysing apparatus includes the usual primary measuring vessel, absorption vessel, and secondary measuring vessel. A branch pipe including a small additional measuring vessel connects the primary measuring vessel with the pipe connecting the absorption vessel with the secondary measuring vessel. This small additional vessel thus contains neutral gas, which is alternately forced into the absorbing vessel and into the secondary measuring vessel. This gas supplies the pressure necessary to effect a measurement in the second measuring vessel, and thus enables readings to be obtained up to 100% absorption.—W. F. F.

Quantitative analysis of colour; Instrument for the ——. A. E. Bawtree. E.P. 154,671, 25.8.19.

The operation of the instrument depends upon the principle that any shade of colour may be obtained by mixture in suitable proportions of two or more of the primary colours, scarlet, green, and violet-blue. Light from a single source is divided into two parts, one of which illuminates the sample to be tested while the other passes through three or more adjacent but not superimposed coloured screens or filters, the coloured beams thus produced being subsequently combined. A calibrated device is provided for regulating the quantity of white light illuminating the sample and for determining the relative intensities of the coloured beams transmitted by the three coloured screens when the colour afforded by the combined colours matches the colour of the sample. For the examination more especially of opaque objects, a slotted reflector is provided in the path of the coloured beam, enabling the sample illuminated by white light to be viewed through the slot.—J. S. G. T.

Carbon, hydrogen, and nitrogen determinations; New micro-combustion furnace for ——. W. Dautwitz. Chem.-Zeit., 1920, 44, 963.

The furnace, which can be used for ordinary combustions or for nitrogen determinations, is mounted, together with absorption stands, on a single board for convenience in moving. The combustion tube is heated from the sides by gas jets from two parallel gas tubes fed from three Bunsen burners which are fixed to the board and adapted as supports for the furnace. (*Cf.* J.C.S., Feb.)—J. H. L.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

American Coke and Chemical Co. By-product condensers. 1553. Jan. 10. (U.S., 17. and 15.)

Brown. Autoclaves. 2531. Jan. 19.

Cartner, Clewer, and Mather and Platt. Vacuum filtration apparatus. 2799. Jan. 21.

Catlin Shale Products Co. Decolorising-materials. 1314. Jan. 10. (U.S., 25.4.16.)

Chem. Fabr. Worms. Distillation. 1575. Jan. 10. (Ger., 6.8.17.)

Dinglers'che Maschinenfabr. A.-G. Purifying gases and vapours. 1532. Jan. 10. (Ger., 1.9.13.)

Gerken. Furnaces. 1408—1410. Jan. 10.

Griffith. Grinding-machines. 1551. Jan. 10. (U.S., 18.4.18.)

Hernu. Apparatus for purifying and treating gases. 1198. Jan. 10. (Fr., 9.12.18.)

Hodge and others. 1946. *See* VII.

Hulsmeyer. Separating air and gases from boiler feed-water etc. 1505—6. Jan. 10. (Ger., 11.11.13 and 11.10.15.)

Kestner. Abstracting gases from water by metallic filters. 1399, 1400. Jan. 10. (Fr., 10.6 and 22.7.20.)

Kestner. Distillation of water. 1402. Jan. 10. (Fr., 15.6.20.)

Kestner. Metallic media for fixing oxygen of water in apparatus for abstracting gases from liquids. 2275. Jan. 17. (Fr., 9.6.20.)

Kestner. Heating and decanting apparatus for purifying feed-water. 2817. Jan. 21. (Fr., 12.6.20.)

Krause. Mixing granular substances. 1976. Jan. 13.

Lundie. Filtering apparatus. 2070. Jan. 14.

Mather. Pre-heaters, heat-exchangers, condensers, etc. 1786. Jan. 11.

Reid. Furnaces. 2448. Jan. 18.

Rialland. Centrifugal separator for clarifying liquids. 1746. Jan. 11. (Fr., 30.4.19.)

Rippl. 1528. *See* II.

Salenius. Centrifugal separators. 1248—1250. 1253—5, 1259—1262. Jan. 10.

Vaccaro. Desiccators. 2581. Jan. 19.

Vernon. Tunnel ovens or kilns. 2036. Jan. 14.

Wade (Schneible). Distilling. 2003. Jan. 13.

Complete Specifications Accepted.

3701 (1918). Paterson. Filtering apparatus. (156,270.) Jan. 19.

6069 (1919). Kirke. Boiler furnaces. (156,826.) Jan. 26.

15,543 and 32,529 (1919). Kermode. Furnaces. (156,834.) Jan. 26.

16,148 (1919). Derneden. Rotary furnaces. (156,835.) Jan. 26.

21,188 (1919). McLaughlin. Pulverising apparatus. (156,852.) Jan. 26.

24,516 (1919). Steinmuller. Travelling-grate furnaces. (133,691.) Jan. 19.

19,126 (1920). Still. Treating crude gas liquor to obtain ammonia solution. (147,099.) Jan. 19.

III.—TAR AND TAR PRODUCTS.

Applications.

Andrews, Conover, John, and Ruth. Purification of naphthalene. 2554. Jan. 19.

American Coke and Chemical Co. 1553. *See* I.

Mauthner and Pfeifer. Production of halogen derivatives from hydrocarbons. 1146. Jan. 10. (Hungary, 20.11.18.)

Otto. Treatment of tar oils etc. 2297. Jan. 17. (Ger., 17.1.20.)

Raschig. Recovery of benzol hydrocarbons from coke-oven gas. 1509. Jan. 10. (Ger., 23.11.13.)

Complete Specifications Accepted.

2366 (1918). Steele and Robertson. Conducting fusions with molten caustic soda or caustic potash. (156,269.) Jan. 19.

15,454 (1920). Kinzlberger u. Co. Purification of crude anthracene. (144,656.) Jan. 26.

IV.—COLOURING MATTERS AND DYES.

Applications.

Davies, and Scottish Dyes, Ltd. Production of colouring matters of the anthraquinone series. 1991. Jan. 13.

Lüers. 1593. *See* XVIII.

Phillips. Artificial dyes. 2493. Jan. 19.

Complete Specification Accepted.

14,767 (1920). Imray (Monsanto Chemical Works). Manufacture of phthaleins. (157,030.) Jan. 26.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

British Cellulose and Chem. Manuf. Co., and Dickie. Coating processes and apparatus. 2694. Jan. 20.

British Cellulose and Chem. Manuf. Co., and Addy. Manufacture of articles of plastic materials. 2695. Jan. 20.

Budde, and Hendon Paper Works Co. Substitute for celluloid. 2109. Jan. 14.

Clavel. Treatment of cellulose acetate. 1911. Jan. 12.

Dreaper. Manufacture of artificial silk etc. 2598. Jan. 19.

Gierisch and Waentig. Obtaining cellulose. 1562. Jan. 10.

Gierisch, Waentig, and Krais. Production of single fibres from bast fibre bundles, with simultaneous disintegration and removal of wood particles etc. 1566. Jan. 10. (Ger., 4.4.19.)

Kämpf. Apparatus for reducing alkali cellulose etc. 1832. Jan. 12. (Ger., 13.1.20.)

McKellar. Treatment of textile fibres to remove grease, wax, etc. 1968. Jan. 13.

Pollacsek. Manufacture of mastic or binding substance from sulphite lye. 1608. Jan. 10. (Austria, 17.10.19.)

Sabner. Degumming etc. textile fibres. 2680. Jan. 20.

Salmon. Bleaching fibres in manufacture of paper. 2099. Jan. 14.

Soc. Anon. la Cellophane. Bands of cellulosic material. 2587. Jan. 19. (Fr., 4.3.20.)

Soc. Anon. la Cellophane. Straw, hair, etc., manufactured from cellulose material. 2588. Jan. 19. (Fr., 4.3.20.)

Complete Specifications Accepted.

16,617 (1919). Picard. Extraction of fibres from flax straws or waste. (156,281.) Jan. 19.

16,861 (1920). Badische Anilin- u. Soda-Fabrik. Manufacture of solutions of cellulose acetate. (145,511.) Jan. 26.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Crompton. Treatment of printed fabrics. 2732. Jan. 21.

Hermon and McKerrow. Production of ornamental effects on silk etc. 1881. Jan. 12.

Krantz. Means for dyeing yarn on bobbins. 1343—6. Jan. 10. (Ger., 4.10 and 12.11.13, 12.1.14, 17.1.17.)

Krantz. Drying textile materials. 1350. Jan. 10. (Ger., 15.1.17.)

Morgan. Dyeing-machines. 2418. Jan. 18.

Pollak. Production of stiffening agents. 1341. Jan. 10. (Ger., 6.11.19.)

Salmon. 2099. *See* V.

Complete Specifications Accepted.

23,232 (1919). Walsh and Tomlinson. Apparatus for printing and sizing yarns etc. (156,302.) Jan. 19.

25,437 (1919). Calico Printers' Assoc., and Costobadie. Treatment of cloth. (156,913.) Jan. 26.

26,227 (1919). Hunt. Apparatus for bleaching treatment of open fabrics. (156,359.) Jan. 19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Brat. Recovery of ammonia from peat. 1447—8. Jan. 10. (Ger., 21.10 and 20.7.18.)

British Cellulose and Chem. Manuf. Co., and Bader. Manufacture of pyrosulphates. 2693. Jan. 20.

Delarozière. Manufacture of sodium and potassium ferrocyanide. 2224. Jan. 17.

Deuts.-Luxemburgische Bergwerks- u. Hütten-A.-G., and Hilpert. Treatment of waste sulphuric acids. 1415. Jan. 10. (Ger., 12.5.16.)

Foster. 1690. *See* IX.

Helbronner and Pipereaut. Manufacture of sulphuric acid. 1191. Jan. 10. (Fr., 29.4.18.)

Hodge, and Ovens and Sons. Sulphuric acid valves. 1946. Jan. 13.

Lidholm and others. 2411. *See* XVI.

Lunden and Thorssell. Production of nitrogen compounds. 2589. Jan. 19.

Lunden and Thorssell. Preparation of a mixture of compounds of alkaline-earth metals and carbon for absorption of nitrogen. 2914. Jan. 22.

New Jersey Zinc Co. 2104 and 2119. *See* XIII.

Parrish and others. 1790. *See* X.

Pearson. 2281. *See* XIII.

Wallin. 1687. *See* IX.

Complete Specifications Accepted.

24,386 (1919). South Metropolitan Gas Co., and Parrish. Manufacture of sulphuric acid. (156,328.) Jan. 19.

24,925 (1919). Wade (Lindsay Light Co.). Manufacture of insoluble thorium compounds. (156,892.) Jan. 26.

25,479 (1919). Dreyfus. Manufacture of acetic acid. (156,916.) Jan. 26.

28,278 (1919). South Metropolitan Gas Co., and Parrish. Means for drying salts. (156,963.) Jan. 26.

32,414 (1919). Toniolo, and Officine Elettrochim. Dr. Rossi. Production of hydrogen and mixtures of hydrogen and nitrogen. (152,975.) Jan. 19.

19,126 (1920). Still. *See* II.

19,675 (1920). Bea. Manufacture of copper sulphate. (147,689.) Jan. 26.

VIII.—GLASS; CERAMICS.

Applications.

Koppens. Tunnel kilns for pottery, lime-burning, etc. 1529. Jan. 10.

Pazsiczky. Producing spun glass. 1277. Jan. 10. (Ger., 7.4.19.)

Sutton. Colouring or treating glass etc. 2045. Jan. 14.

Vernon. 2036. *See* I.

Complete Specifications Accepted.

11,002 (1920). Rollason. Manufacture of refractory materials for furnace linings. (156,447.) Jan. 19.

26,523 (1920). Rheinberg. Producing reflecting surfaces on glass by means of metals of the platinum group. (156,472.) Jan. 19.

IX.—BUILDING MATERIALS.

Applications.

Berry. Manufacture of artificial stone, cement, etc. 2319. Jan. 17.

Foster. Production of lime for building, together with ammonia and a gas for power purposes. 1690. Jan. 11.

Renyi and Renyi. Bricks etc. 1356. Jan. 10. (Austria, 10.1.14.)

Renyi and Renyi. Building materials for use as wood substitutes. 1355 and 1358. Jan. 10. (Austria, 10.1 and 9.5.14.)

Wallin. Production of steinholz from magnesia and magnesium salts. 1687. Jan. 10. (Ger., 12.3.14.)

Complete Specifications Accepted.

18,844 (1918). Atkins and Colquhoun. Manufacture of bricks, clinker, etc. (156,820.) Jan. 26.

7901 and 11,042 (1920). Fabr. Akt. Kronstein. Insulating and building material. (140,431 and 142,111.) Jan. 19.

9786 (1920). Forrester (Internat. Isolations Komp.). Manufacture of porous stones for thermal insulating purposes. (156,442.) Jan. 19.

10,435 (1920). Holzbearbeitungs Ges., Haring, and Voit. Drying wood. (141,727.) Jan. 26.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Ashcroft. Metallurgy of lead and zinc and their sulphides. 2068. Jan. 14.

Ballantine. Manufacture of ferro chromium alloys. 2592. Jan. 26.

Basset. Direct production of iron, steel, iron alloys, etc. 1318-9. Jan. 10. (Fr., 2.10.18, 20.12.17.)

Bishop. Removing metallic constituents from a mixture thereof. 1890. Jan. 12. (U.S., 14.1.20.)

British Thomson-Houston Co. Platinum alloys. 1920. Jan. 12. (U.S., 5.3.14.)

Cliff. Treating scrap iron. 2585. Jan. 19.

Corsalli. Enriching iron alloys poor in silicon and manganese. 1655 and 1658. Jan. 10. (Ger., 27.6 and 27.7.17.)

Corsalli. Smelting iron and steel scrap. 1656. Jan. 10. (Ger., 8.5.18.)

Corsalli. Smelting. 1657, 1659, 1660. Jan. 10. (Ger., 2.6.16., 18.9.13, 20.3.18.)

Corsalli. Furnaces. 1661. Jan. 10. (Ger., 6.5.19.)

Davies. Steel or iron nickel welding. 1824 and 1826. Jan. 12.

Diepschlag. Regulating working of waste gases in blast furnace operations. 1757. Jan. 11. (Ger., 30.6.20.)

Dunkley and Ryan. White metal alloy. 2569. Jan. 19.

Halbergerhütte Ges. Purification of blast-furnace etc. gases. 2310 and 2696. Jan. 17 and 20. (Ger., 1.12.20.)

Halbergerhütte Ges. Air and gas purifiers. 2311 and 2697. Jan. 17 and 20. (Ger., 1.12.20.)

Kubasta. Heat treatment of steel. 1194. Jan. 10.

Linnmann. Production of raw or cast iron clippings. 1206. Jan. 10. (Ger., 28.4.19.)

Lohmann. Manufacture of blocks from wolfram, molybdenum, etc. 1449, 1452–3. Jan. 10. (Ger., 2 and 29.1 and 16.4.14.)

Lohmann. Manufacture of hard but ductile tools. 1475. Jan. 10. (Ger., 7.12.18.)

Lohmann. Manufacture of hard alloys. 1480. Jan. 10. (Ger., 7.12.18.)

Lohmann. Withdrawing carbon from alloys of high melting temperatures. 1488. Jan. 10. (Ger., 13.1.19.)

Loke. Manufacture of ferrous titanium or refined iron or steel. 1404. Jan. 10.

Parrish, Weight, and South Metropolitan Gas Co. Treatment of waste liquor from wet extraction of copper. 1790. Jan. 11.

Platt. Repairing aluminium sheet and castings and attaching copper, brass, steel, etc. thereto. 2849. Jan. 22.

Slatineanu. Electrolytic separation of platinum from other metals 1500. Jan. 10. (Switz., 19.12.19.)

Volmer. Production of copper coatings on non-metallic materials. 1300. Jan. 10. (Ger., 12.11.19.)

COMPLETE SPECIFICATIONS ACCEPTED.

23,960 (1919). Ashcroft. Treatment of ores or other metal-bearing materials. (156,866.) Jan. 26.

4864 (1920). Levoz. Manufacture of soft cast-iron. (140,756.) Jan. 26.

9651 (1920). Metropolitan-Vickers Electrical Co. Improving the magnetic qualities of magnetisable materials. (141,348.) Jan. 26.

26,523 (1920). Rheinberg. *See* VIII.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Adam and Antonoff. Electric batteries. 1592. Jan. 10.

British Thomson-Houston Co. (General Electric Co.). Electric furnaces. 2417. Jan. 18.

British Thomson-Houston Co. (General Electric Co.). Electrodes, and methods of making same. 2911. Jan. 22.

Cattley. Accumulator plates. 1291. Jan. 10.

Electrosynthese Ges. Carrying out electro-chemical gas reactions. 2269. Jan. 17. (Austria, 19.7.17.)

Juchli. Production of electric insulating material. 1340. Jan. 10. (Switz., 8.8.19.)

Rankin, and Van Raden and Co. Electric accumulators. 2899. Jan. 22.

Slatineanu. 1500. *See* X.

COMPLETE SPECIFICATIONS ACCEPTED.

17,821 (1919). Akt. Kfafveindustri. Heating material or performing chemical processes in electric furnaces. (141,656.) Jan. 26.

7901 and 11,042 (1920). Fabr. Akt. Kronstein. *See* IX.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Chadbourne. Manufacture of soap. 1460. Jan. 10.

Du Pont de Nemours and Co. Removing odours from treated oils. 1322. Jan. 10. (U.S., 13.6.18.)

Faester. Recovering oil from fish liver etc. 1547. Jan. 10. (Norway, 15.10.19.)

Gonyers, Reynard, and Lanoline Extractors, Ltd. Treatment of wool fats etc. 2917. Jan. 22.

Wright. Manufacture of margarine etc. 2633. Jan. 20.

COMPLETE SPECIFICATION ACCEPTED.

25,213 (1919). Bollmann. Extraction of fat or oil from raw materials. (156,905.) Jan. 26.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Clerc and Nihoul. Manufacture of zinc white. 1588. Jan. 10. (Fr., 15.11.19.)

Koller. Manufacture of synthetic resins. 2065. Jan. 14.

New Jersey Zinc Co. Manufacture of French oxide. 2104. Jan. 10. (U.S., 31.3.20.)

New Jersey Zinc Co. Manufacture of zinc oxide. 2119. Jan. 10. (U.S., 28.6.20.)

Pearson. Manufacture of zinc oxide. 2281. Jan. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

9433 (1919). Lillie. Poison compositions for use as antifouling paints etc. (156,827.) Jan. 26.

24,978 (1919). Howse. Solutions of phenol-aldehyde condensation products. (156,896.) Jan. 26.

29,417 (1919). Nishizawa. Sulphide composition for painting which resists the action of light and heat. (156,971.) Jan. 26.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Hopkinson. Products obtained from rubber-containing latex. 1769. Jan. 11. (U.S., 16.1.20.)

Hopkinson. Treatment of rubber-containing latex. 1782. Jan. 11. (U.S., 16.1.20.)

Western Rubber Co. Rubber substitute. 1561. Jan. 10. (U.S., 16.3.18.)

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Burger. Tawing and currying leather. 1640. Jan. 10. (Ger., 14.5.14.)

Chem. Fabr. Worms. Tanning hides. 1577. Jan. 10. (Ger., 6.8.17.)

Chem. Fabr. Worms. Manufacture of tanning agents. 1578. Jan. 10. (Ger., 31.5.16.)

Chem. Fabr. u. Asphaltwerke. Manufacture of tanning agents and process of tanning therewith. 1583-4. Jan. 10. (Ger., 21.6 and 17.7.16.)

Lamplough, and Townmead Construction Co. Material for use as a binder. 2467. Jan. 18.

Reubig. Clearing, removing colour from, and finishing leathers. 1595. Jan. 10. (Ger., 25.7.16.)

COMPLETE SPECIFICATION ACCEPTED.

10,445 (1920). Jackson (Dorr Co.). Recovery of proteids from waste liquors of the hide-treating art. (156,444.) Jan. 19.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Lidholm, and Wargöns Aktiebol. Producing cyanamide from calcium cyanamide. 2411. Jan. 18. (Sweden, 3.3.20.)

COMPLETE SPECIFICATION ACCEPTED.

12,571 (1920). Hamler. Fertiliser dryers. (143,846.) Jan. 26.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Campbell. Manufacture of starch. 1800. Jan. 11.

Kowalski. Obtaining sugar from extractions and molasses. 2296. Jan. 17.

COMPLETE SPECIFICATION ACCEPTED.

22,774 (1919). Kowalski. Manufacture of a precipitate rich in albumen and poor in ash from raw juices and waste liquors of sugar factories. (132,798.) Jan. 19.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Bevan. Siphons for making beer etc. 2738—9. Jan. 21.

Bevan. Vats for fermenting beer etc. 2740. Jan. 21.

Lüers. Production of colouring-medium for beers etc. 1593. Jan. 10. (Ger., 17.12.19.)

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Bartmann. Producing flour from corn. 2821. Jan. 21.

Berczeller and Graham. Synthetic milk. 1264—5. Jan. 10. (Austria, 26.7.19, 7.1.20.)

Candy Filter Co. Destruction of micro-organisms in liquids. 1190. Jan. 10. (Austria, 8.1.20.)

Cholet. Preserving meat, fish, etc. 2692. Jan. 20.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Bosshard, Strauss, and Elektrochem. Werke. Production of condensation products. 1627–8. Jan. 10. (Ger., 9.8.18, 4.7.19.)

Bräunig and Wohl. Production of glyoxal. 1241. Jan. 10. (Ger., 29.6.16.)

Farbw. vorm. Meister, Lucius, u. Brüning, Manufacture of complex aurothiophenols. 1579. Jan. 10. (Ger., 22.4.16.)

Farbw. vorm. Meister, Lucius u. Brüning. Manufacture of phlorobutyrophenone, phloroisobutyrophenone, and their homologues. 1580. Jan. 10. (Ger., 3.11.17.)

Haakh. Manufacture of oxyarylaldehydes. 1576. Jan. 10. (Ger., 6.2.18.)

Mauthner and Pfeifer. 1146. *See* III.

Morgan and Vining. Production of aromatic aldehydes. 2480. Jan. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

2366 (1918). Steele and Robertson. *See* III.

24,388 (1919). British and Foreign Chemical Producers (Rhein. Kampfer-Fabr.). Maufacture of p-cymene. (156,329.) Jan. 19.

14,767 (1920). Imray (Monsanto Chem. Works). *See* IV.

17,795 (1920). Boehringer Sohn. Obtaining the active ingredient of *Lobelia inflata*. (145,621.) Jan. 26.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Dorian. Colour photography. 2720. Jan. 20. (Fr., 21.1.20.)

Gorsky. Three-colour photography. 1879. Jan. 12.

Kühn. Photographic printing processes. 1527. Jan. 10. (Ger., 26.7.16.)

COMPLETE SPECIFICATION ACCEPTED.

9895 (1920). Dourlen and Chretien. Colour photography. (141,368.) Jan. 19.

XXII.—EXPLOSIVES; MATCHES.

APPLICATION.

Coleman. Method of making slow-burning matches. 1977. Jan. 13.

COMPLETE SPECIFICATION ACCEPTED.

4597 (1920). Eschbach. Manufacture of initial explosive priming compositions. (156,429.) Jan. 19.

I.—GENERAL; PLANT; MACHINERY.

Silica gel; Adsorption [of vapours] by ——. E. B. Miller. Chem. and Met. Eng., 1920, 23, 1155—1158, 1219—1222, 1251—1254.

The phenomena of adsorption of vapours have been investigated with silica gel, prepared by coagulation of a colloidal solution of silicic acid, this material being specially applicable inasmuch as it is easily reproducible, is inert, and is stable even at high temperatures. The factors which influence the adsorption of vapours are the ratio of the partial pressure of the vapour to its vapour pressure at the temperature of adsorption, this ratio being termed the "corresponding pressure," and the compressibility of the adsorbed liquid, and to secure activity of the adsorbent it must have as large an internal volume as possible made up of spaces of minimum dimensions. Laboratory-scale experiments were carried out on the adsorption and recovery of sulphur dioxide, ether, acetone, benzene, water, and petroleum ether. In the case of sulphur dioxide the rate of flow was 40 c.c. per min. per g. of gel, giving a time of contact of 0·8 sec. For a certain period adsorption reached 100%, after which it gradually fell to zero; at the "break point" for all concentrations of the vapour the gel showed 57% saturation. Size of the gel particles affects adsorption. Recovery of the sulphur dioxide was effected by heating the gel to 100° C. and introducing air; in this way any desired concentration may be obtained. In experiments with volatile solvents these were recovered after adsorption by heating the gel to 105° C. and then admitting steam. The amounts recovered with ether, acetone, benzene, and petroleum ether were 84·7 and 90·4%; 82 and 93·5%; 86·5 and 95·5%; and 84·7 and 94·5%, respectively; the results are shown graphically. The adsorption of water by the gel is increased if the water content of the latter is 5—7%; to remove the water the gel is heated to 125° C. in a current of air. A plant for effecting adsorption on a semi-commercial scale is described. The results obtained with it prove the applicability of adsorption by silica gel to industrial processes such as air drying, recovery of gasoline from gas wells and prevention of loss in storage tanks, solvent recovery, recovery of vapours such as sulphur dioxide and nitrogen oxides, and separation of gases from mixtures.—W. J. W.

Patents.

Centrifuges. C. A. Fesca & Sohn, Assees. of L. von May. E.P. (A) 137,827 and (B) 145,397, 12.1.20. Conv., 26.6.15 and 18.6.19.

(A) The basket of a centrifugal machine is made without a top rim, and is mounted so that it can be raised against an annular disc which rotates in separate bearings and retains the solid matter. When the basket is lowered (without stopping the rotation) the solid material is automatically discharged. (B) The annular disc has a cylindrical upward extension forming a feed duct, above which is a fixed feed hopper with inlet and outlet valves controlled by one face of a double cam, the other face of which operates on the footstep bearing of the basket, so that the various motions are operated in correct sequence.—B. M. V.

Acid-resisting receptacles, such as boilers, pipes, and the like. F. Krupp A.-G. E.P. 145,732, 2.7.20. Conv., 17.6.18.

The inner wall of the vessed is composed of acid-resisting iron, the outer wall of, *e.g.*, ordinary iron, and the space between is filled with lead by casting.—B. M. V.

Drying apparatus. T. Allsop and W. W. Sibson, Assrs. to The Philadelphia Drying Machinery Co. U.S.P. 1,355,117, 12.10.20. Appl., 4.8.19.

A number of carriers for the goods to be dried are disposed within an enclosure so that their vertical ends form a number of transverse channels. Means are provided for circulating air in a number of independent courses each comprising adjacent channels.—J. S. G. T.

Drying machine. M. F. Mangelsdorff. U.S.P. 1,355,238, 12.10.18. Appl., 14.9.18.

Heated air is admitted to a casing containing a series of superposed trays, which are perforated and divided into sections or leaves, each leaf being capable of rotation about an axis which is at right angles to the axes of the leaves of the tray next beneath. The sets of leaves are, at intervals, turned through 180° in succession, beginning at the bottom, the material being fed in a uniform layer to the top tray, and when dry, removed from the bottom of the casing by means that prevent escape of heated air.—B. M. V.

Desiccating liquids; Process and apparatus for ——. R. F. Barker. U.S.P. 1,362,590, 21.12.20. Appl., 23.6.19.

The liquid is atomised and evaporated to a viscous state in a drying atmosphere, and collected on a moving heated surface, from which it is removed when completely dry.—B. M. V.

Volatile solvents; Process of recovering ——. U. J. Lebourveau and A. M. Taylor, Assrs. to Atlas Powder Co. U.S.P. 1,355,401, 12.10.20. Appl., 5.3.20.

The solvent vapour is extracted from its mixture with air by means of acetone oil or aniline, which is then distilled and the solvent vapour condensed. —W. F. F.

Air separator. G. S. Emerick, Assr. to Emerick Mill Co. U.S.P. 1,355,596, 12.10.20. Appl., 7.1.19.

The apparatus comprises a casing within which is a chamber containing an upper and a lower receptacle with a space between the two. Walls connected with and extending from the receptacles form an air chamber around the space between the receptacles. The material under treatment is fed into the upper receptacle, and air is supplied through an adjustable passage to the air chamber, and passes through the space between the receptacles and upwards through and around the upper receptacle, carrying with it the lighter particles which are deposited in and removed from the outer casing. The heavier particles pass downwards into the lower receptacle and are discharged through a separate outlet.

Compound still. A. C. Badger. U.S.P. 1,362,666, 21.12.20. Appl., 29.1.17.

A container is provided with a heater at the upper part, a catch pan below the heater, and a condenser in the lower part. Outlets are provided from the catch pan and condenser, there is an inlet for liquid in the lower part of the container and an inlet pipe within the container leading to the condenser from the vapour space above the level of the liquid.—B. M. V.

Fractionating-column. L. V. Rogers. U.S.P. 1,363,485, 28.12.20. Appl., 7.7.19.

A fractionating column detachable from the boiling vessel is fitted with an inverted conical baffle over the vapour inlet at the bottom and with a number of horizontal perforated baffle discs. —L. A. C.

Gravity-kiln. T. F. Anderson. U.S.P. 1,363,215, 28.12.20. Appl., 26.5.20.

A TUBULAR oven is arranged in a slanting position, so that the material therein will travel downwards by gravity, and is heated by hot gases in a channel which first surrounds the oven and then leads vertically away from it, so as to leave the top and mouth of the oven unobstructed.—B. M. V.

Evaporator. R. D. Kehoe. U.S.P. 1,363,323, 28.12.20. Appl., 13.8.19.

IN an evaporator the steam for heating is led vertically downwards through the top of the vessel to a heater in the lower part, and the entrainment separator below the vapour outlet at the top is arranged round the steam inlet so that the vapour must pass close thereto.—B. M. V.

Mixing apparatus. F. A. Browne, Assr. to The Barber Asphalt Paving Co. U.S.P. 1,363,561, 28.12.20. Appl., 12.4.17.

A ROTATING cylindrical drum is provided with sets of baffles on its interior surface, the baffles of any one set being substantially parallel to each other, but extending across the path of material coming from an adjacent set.—B. M. V.

Gases, vapours and liquids; Apparatus for removing mechanically mixed solids from ——. R. Wussow and E. Schierholz. G.P. 324,260, 18.10.18.

THE liquid or gas is directed tangentially into a cylindrical apparatus provided with spiral guides. Outlet passages are connected with these guides round the circumference of the apparatus and are directed downwards. The particles of solid are driven against the periphery of the apparatus and pass into the outlet passages, while the purified liquids or gases pass down through the centre and out through a central outlet tube.—A. R. P.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Sulphur in the coal bed; Distribution of the forms of ——. H. F. Yancey and T. Fraser. J. Ind. Eng. Chem., 1921, 13, 35—37.

ANALYSES of samples of coal from different parts of the coal face showed that pyritic sulphur is extremely irregularly distributed, but the organic sulphur is much more uniform. There appears to be no definite relationship between the occurrence of organic and of pyritic sulphur. High-sulphur coals are ordinarily higher in both types than low-sulphur coals, though organic sulphur makes up a greater percentage of the total sulphur in the case of low-sulphur coals. No difference was found in the percentage of organic sulphur in washed and unwashed coal, and no evidence was obtained of a concentration of organic sulphur in the coal immediately adjacent to pyrites deposits.—W. P.

Sulphur content of coke and gas in the carbonisation of coal; Factors affecting the ——. A. R. Powell. J. Ind. Eng. Chem., 1921, 13, 33—35.

A DETAILED study has been made of the changes the pyritic and organic sulphur in coal undergo during carbonisation. Pyrites itself is completely decomposed at 1000° C., giving ferrous sulphide and free sulphur and a trace of pyrrhotite or magnetic iron sulphide. In coal the decomposition of the pyrites begins at 300° and is complete at 600°, the reaction reaching its maximum at 400°—500° C. From one-quarter to one-third of the organic sulphur is decomposed below 500° C., forming hydrogen sulphide. A small part of the organic sulphur gives volatile organic sulphur compounds which find their way into the tar. The remaining organic sulphur undergoes a decided change in character at 400°—500° C., and shows none of the properties of the original coal sulphur. Coke practically ceases to give off hydrogen sulphide above 600° C., but if hydrogen or gas containing hydrogen is passed through coke above 600° C., a further appreciable evolution of hydrogen sulphide is obtained. The reaction appears to be reversible, and for the removal of appreciable quantities of sulphur large quantities of the gas containing hydrogen must be passed through the coke at a rapid rate.—W. P.

Colloidal fuels, their preparation and properties. S. E. Sheppard. J. Ind. Eng. Chem., 1921, 13, 37—47. (*Cf.* J., 1920, 395 R, 413 R.)

Two types of colloidal fuels are distinguished. The A-type is stabilised by means of a "fixateur" or protective colloid. Soaps, particularly of the alkaline-earth metals, such as calcium soaps, are used as fixateurs. The B-type is stabilised by "peptisation" (or partial solution) with tar or tar distillates. The B-type are more easily prepared than the A-type, but are not completely stabilised. Colloidal fuel prepared by peptisation will remain homogeneous for 3 to 4 weeks, after which the oil and tar begin to separate. A second method of peptisation consists in partial oxidation of the cellulosic constituents of the coal. The machinery

for compounding these fuels consists of a mill for pulverising the coal, coke, etc., storage and blending tanks for the oil bases, and mixing vessels. The cost of manufacture is reckoned approximately at $1·50 per ton, inclusive of fixateur.—W. P.

By-product coke, anthracite, and Pittsburgh coal as fuel for heating houses. H. Kreisinger. J. Ind. Eng. Chem., 1921, **13**, 31—33.

The comparative values of by-product coke, anthracite, and Pittsburgh coal were examined, two steam boilers of the size ordinarily used for heating an average 7-room house being used for the tests. The efficiency obtained with the coke was a little better than that obtained with anthracite and 10—17% better than that obtained with Pittsburgh coal. Per lb. of fuel burned the coke was about 15% better than the Pittsburgh coal, and the anthracite about 9% better than the coke.—W. P.

Low-temperature coking of Utah coals. O. Monnett. Chem. and Met. Eng., 1920, **23**, 1246—1249.

Fifteen 30-lb. samples of different varieties of coal were analysed and examined in regard to their coking power in a 20-g. by-product apparatus at 540° and 700° C., the best ten being further tested in an apparatus of 8-lb. capacity at a maximum temperature of 1000° C. The tabulated results give the amounts of tar, coke, and gas, as well as the composition of the last, and the calorific power of the coal, and analyses of the coal are also quoted. The conclusion arrived at is that Castle Grade coal gives a fair grade of coke, but Sunnyside is the best coking coal, and a good mixture consists of equal parts of Standard and Sunnyside.—W. J. W.

Canadian lignite; Carbonisation of ——. E. Stansfield. J. Ind. Eng. Chem., 1921, **13**, 17—23. (*Cf.* J., 1919, 67 a, 491 a.)

New plant in the course of construction is described. This consists essentially of a strongly heated retort floor, inclined at an angle slightly steeper than the angle of repose of the crushed lignite. The material flows down the heated surface from a hopper at the top, passing under a succession of baffle plates, which control the thickness of the layer. The rate of flow of the material is controlled entirely by the rate of withdrawal from the bottom of the retort. The retort floor should be hottest at the bottom of the retort. Satisfactory results have been obtained with a small model of the same design capable of treating 200 lb. of raw lignite per hr.—W. P.

Ammonia; Influence of steam and gases on the yield of —— *from the carbonisation of coal and oil shales.* A. J. Franks. Chem. and Met. Eng., 1920, **23**, 1149—1154.

In the carbonisation of coal at low tmperatures (not exceeding 500° C.), the predominance of hydrogen over ammonia, and inert gases present, operate against dissociation of the ammonia, and if steam is introduced into the process it exerts a mechanical action in removing the ammonia from the reaction zone before decomposition takes place. At high temperatures the protective action of hydrogen is still more evidenced. At high temperatures with steam, apart from the normal effect of the hydrogen, dissociation of the steam gives rise to formation of large quantities of nascent hydrogen, which effect the synthetic production of ammonia, as indicated by Tervet (J., 1883, 445).—W. J. W.

Producer fire; Effect of cooling the —— *on gas production.* H. Koschmieder. Brennstoff-Chem., 1921, **2**, 3—5.

The heat balance on steaming the producer fire is examined. With large quantities of steam there is an increase in gas yield, but a decrease in calorific value. At the same time there is an increase in the yield of ammonia.—W. P.

Acetylene; Pyrogenic decomposition of —— *in contact with metallic catalysts.* E. Tiede and W. Jenisch. Brennstoff-Chem., 1920, **2**, 5—8.

The temperature at which decomposition of acetylene commenced in contact with different metallic catalysts was determined, and also the percentage decomposition with each metal at 600° C. The most active metals in promoting decomposition were iron, cobalt, nickel, copper, and manganese. The differences observed in the action of different metals are attributed to their varying solvent power for hydrogen, except in the case of the alkali metals, the activity of which is due to the ease with which they form carbides. (*Cf.* J.C.S., Feb.)—W. P.

Coal gas and air; Internal energy of inflammable mixtures of —— *after explosion.* W. T. David. Proc. Roy. Soc., 1920, a, **98**, 303—318.

About 10% of the heat of combustion of coal gas in mixtures with air, has not been converted into thermal energy when the maximum pressure of the explosion has been reached, and an after-burning continues for at least 0·25 sec. after this maximum pressure has been attained. The following figures show the distribution of the energy of combustion at the moment of maximum temperature for mixtures of gas and air containing respectively 15, 12·4, and 9·7% of coal gas:—Internal thermal energy, 81, 78, 72·5% of the total heat of combustion of the coal gas; available chemical energy in unburnt coal gas, 10, 12, 9·5%; heat loss to walls of vessel, 9, 10, 18%. (*Cf.* J.C.S., Feb.)—J. F. S.

Combustions; Mechanism of some ——. H. von Wartenberg and B. Sieg. Ber., 1920, **53**, 2192—2202.

Carbon monoxide must be moist before it will react with oxygen at ordinary flame temperatures, but the amount of water necessary to promote explosion of the ideal mixture is just the same whether the oxygen is provided as such or as nitrous oxide, and is roughly that quantity which corresponds with a partial pressure of 0·5 mm. The carbon monoxide flame contains hydrogen as well as formic acid (Wieland, J., 1912, 333 a), and therefore Dixon's theory of the mechanism of the combustion (J., 1886, 370), in which the first stage is the union of carbon monoxide and water to formic acid, is completely proved. The union of hydrogen and oxygen at 600°—1000° C. also begins by a direct addition, namely the formation of hydrogen peroxide, for the amount of this which may be proved to be present in the products when the combustion tube is rapidly cooled, is about one million times as great as would be formed by the secondary oxidation of water under the same conditions. The hydrogen peroxide, however, rapidly decomposes into water and oxygen, some of which changes to ozone, which persists better than the hydrogen peroxide. (*Cf.* J.C.S., Feb.)—J. C. W.

Gasoline losses due to incomplete combustion in motor vehicles. A. C. Fieldner, A. A. Straub, and G. W. Jones. J. Ind. Eng. Chem., 1921, **13**, 51—58.

Analyses of exhaust gases have been carried out in order to examine the gasoline losses in motor engines due to imperfect combustion. The composition of the exhaust gases from individual machines varies greatly, the controlling factor being the air-gasoline ratio supplied to the cylinders. The percentage of carbon monoxide in the exhaust gas lies between 5 and 9%, the average for 23 cars tested being 6·7%, and the heat lost in unburnt

gases passing into the exhaust is about 30% of the total heat value of the gasoline supplied. The maximum loss takes place when operating for full power on heavy load with rich mixtures.—W. P.

Oils and other liquids; Viscosity of —— as a function of temperature. H. Schwedhelm. Chem.-Zeit., 1921, 45, 41—42.

Determinations of the viscosity of mineral oils at different temperatures showed that the viscosities may be calculated approximately by the formula $z/G=(z'/G)^{H^{t'-t}}$, where z and z' are the absolute viscosities at temperatures t and t', and G and H constants. G and H have the following values:—mineral lubricating oils, 0·01887—0·02357, 1·01485—1·01858; rape oil, 0·01887, 1·01218; water, 0·00145, 1·01278; alcohol, 0·000160, 1·00441.—W. P. S.

Coke-oven refractories. Hancock. *See* VIII.

Patents.

Furnaces; Pulverised fuel ——. L. H. Bergman. E.P. 155,731, 17.3.20.

Air is injected into a combustion chamber through two concentric nozzles, and powdered fuel is also injected into the central nozzle to mix with the air. The mixed streams of air and fuel are directed downwards towards the forward end of the combustion chamber, and are then diverted to the rear of the chamber and thence through an outlet leading to a boiler.—W. F. F.

Furnace and the process of combustion of pulverulent and other fuel adapted for steam boilers. F. Seymour. U.S.P. 1,355,172, 12.10.20. Appl., 6.1.19.

Fuel and air are mixed in the exact proportions that are necessary for complete combustion and introduced as a blast into the combustion chamber, which is provided with walls of refractory material. The walls are heated to incandescence and the combustible material is ignited in contact with them. The maximum combustion temperature is obtained, and the gas is brought into contact with a steam generator after combustion is substantially complete. The melted residue is discharged through a water-cooled opening into a water-cooled ash-pit without agglomeration.—W. F. F.

Distillation or gasification of organic matter or minerals containing organic matter; Process of and oven for the continuous ——. F. Rippl, Assr. to The Chemical Foundation, Inc. U.S.P. 1,355,268, 12.10.20. Appl., 8.8.16.

The material is placed in receptacles and moved along an oven passage which is heated externally. In the preheating zone the oven is heated in one part only at its sole and in another part only at its lateral walls, whilst in the distillation zone it is heated at its sole as well as its lateral walls. In the final zone the material is cooled by means of the combustion air which is supplied to the oven.—W. F. F.

Gas producers. J. M. Wallwin. E.P. 155,679, 14.10.19.

In a suction gas producer having a circular stepped grate with central apertures in the grate plates, the plates are in the form of concentric truncated cones to facilitate the passage of ash. The bottom plate includes a movable piece to allow of clinkering.—C. I.

Gas producer. Bergmann Elektrizitäts-Werke A.-G. G.P. 323,769, 10.11.17.

The fire-grate of a gas producer is roof-shaped and is movable along the direction of the ridge. In order to prevent conglomeration and piling up of the coke, and to effect its reduction to small fragments, the fire-grate is further provided with projections which operate against other fixed projections and thereby impart an active movement to the mass.—W. J. W.

Hydrocarbons; Apparatus for treating ——. Art of cracking [petroleum] hydrocarbons. J. W. Coast, jun., Assr. to The Process Co. U.S.P. (A) 1,355,311 and (B) 1,355,312, 12.10.20. Appl., 5.5 and 27.9.17.

(A) The vapour from a still bubbles through a body of hydrocarbon oil contained in a reservoir and then through a reflux condenser which returns the condensed liquid to the reservoir, whence it flows by gravity through an overflow pipe into the still. The vapour not condensed in the reflux condenser passes into a main condenser. (B) In the apparatus described in U.S.P. 1,353,316 (J., 1920, 742 A), the oil is filtered both before and after passage through the pipe element to remove coke-forming matter.—L. A. C.

Gasoline; Manufacture of —— [from oil well gas]. G. H. Taber, jun., Assr. to Mexican Sinclair Petroleum Corp. U.S.P. 1,363,487, 28.12.20. Appl., 24.5.19.

Oil and gas are withdrawn from an oil well under high pressure; a portion of the gas is released under a lower pressure sufficiently high to prevent much volatilisation of gasoline, a further portion is then released at a still lower pressure, and gasoline is extracted from this portion.—L. A. C.

[Motor] fuel; Method of forming a liquid ——. A. Hayes, Assr. to U.S. Industrial Alcohol Co. U.S.P. 1,363,870, 28.12.20. Appl., 18.6.19.

Alcohol vapour is passed into a mixture of about 50 pts. of kerosene, 14 pts. of benzol, and 3 pts. of ether.—L. A. C.

Coking retort ovens. W. J. Mellersh-Jackson. From The Koppers Co. E.P. 155,316, 23.6.19.

See U.S.P. 1,312,372 of 1919; J., 1919, 710 A.

Lubricating oil; Process of purifying ——. C. H. Hapgood, Assr. to The De Laval Separator Co. U.S.P. 1,363,784, 28.12.20. Appl., 23.4.19. Renewed 17.11.20.

See E.P. 142,089 of 1920; J., 1921, 38 A.

Furnaces [gas producers]; Rotary grates for ——. J. Lambot. E.P. 141,056, 31.3.20. Conv., 3.4.19.

Hydrogen. U.S.P. 1,363,488. *See* VII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

Wood alcohol; Process for the manufacture of ——. L. F. Hawley. U.S.P. 1,363,730, 28.12.20. Appl., 19.10.20.

Wood is treated with sodium carbonate and subjected to destructive distillation.—L. A. C.

Retorts; Vertical —— [for distillation of bituminous materials]. K. Barthel. G.P. (A) 323,958 and (B) 323,959, 26.9.18.

(A) The material is delivered from a preheating chamber, by means of a revolving hollow drum, to the uppermost of a series of superposed plates in a

vertical retort, and is moved over the plates and from one plate to the next lower one by rotating scrapers. In the production of low-temperature tar from bituminous materials, the hollow shaft carrying the scrapers serves as a superheater for the steam which is introduced, and a better distillation is thereby secured. At the same time the temperature of the gases is appreciably lowered and their decomposition prevented. (B) In a vertical retort provided with plates and scrapers, the products of distillation from different zones are drawn off separately and their fractionation is thus facilitated.—W. J. W.

Incandescence electric lamps; Filament for ——. R. E. Myers and R. D. Hall, Assrs. to Westinghouse Lamp Co. U.S.P. 1,363,162, 21.12.20. Appl., 14.5.15.

A FILAMENT which tends to offset in use consists of tungsten and at least two of a group of substances including the oxides of the alkalis, alkaline earths, beryllium oxide, calcium oxide, and titanium oxide. —J. S. G. T.

Distilling coal and other materials; Process of and apparatus for ——. W. Thomas. U.S.P. 1,365,128, 11.1.21. Appl., 15.11.16. Renewed 28.10.20.

SEE E.P. 110,217 of 1916; J., 1917, 1230.

III.—TAR AND TAR PRODUCTS.

Sulphur in coal tar oils. Weissgerber. Brennstoff-Chem., 1921, 2, 1—3.

THE sulphur in coal tar oil exists mainly as compounds containing the thiophene ring, either alone or in the form of condensation products. These compounds are very stable and so are particularly difficult to remove. Metals have been used for the purification of the oils. The alkali metals act vigorously at comparatively low temperatures (110°—120° C.), but the reaction is much slower with the heavy metals, and nickel steel and cast iron are practically inactive. The use of sodium is out of the question, not only on account of its prohibitive price, but also because of the presence of phenols in the oils. For practical purposes copper and zinc have been much used, but here also the cost of purification is high.—W. P.

Phenols from low-temperature tar; Action of —— upon metals. U. Ehrhardt and G. Pfleiderer. Brennstoff-Chem., 1921, 2, 9.

THE solubility of metals in the oils from low-temperature tar was determined. The oils used were obtained by mixing 100 c.c. of first runnings, 600 c.c. of the fraction of b.p. 150°—250° and 300 c.c. of b.p. 250°—270° C. The mixture was saturated with water and was shaken with the metal to be tested (in most cases in the form of strips) in contact with air for a period of 4 weeks. The amounts dissolved in mg. per sq. cm. were as follows: copper, 6·5; brass, 0·6; German silver, 0·9; zinc, 1·2; galvanised iron, 0·73; nickel (wire), 0·09; nickel-plated brass, 0·17; lead, 1·1; aluminium, 0·0; tinplate, 0·22; sheet iron, 0·51; pickled sheet iron, 0·04; silicon iron (18%), 0·0; V2A-steel (Krupp), 0·0.—W. P.

Sulphonic acids; Identification of —— in the form of salts formed with aromatic bases. C. F. van Duin. Rec. Trav. Chim., 1921, 40, 99—102.

SULPHONIC acids can be identified by means of their salts with aromatic bases (*cf.* Ambler and Wherry, J., 1920, 815 A) and these salts can be analysed by titration with $N/10$ sodium hydroxide in the presence of phenolphthalein as indicator. This has been applied successfully in a number of cases. (*Cf.* J.C.S., Feb.)—W. G.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Dyestuffs; Process of producing ——. E. Hart and I. J. Stewart. E.P. 155,726, 21.2.20.

FINELY divided vegetable matter, such as the wood, bark, leaves, or the like of certain trees and shrubs, is heated with a solution prepared by boiling sodium carbonate and lime in water and separating the calcium carbonate by filtration. When extraction of the colour is complete, the solution is filtered and may be used direct for dyeing or may be concentrated to a paste or to dryness. A wide range of dyestuffs can thus be extracted from different varieties of the following species: eucalyptus, exocarpus, acacia, mallotus, casuarina, banksia, and aster.—L. A. C.

Disazo dye. T. H. Leaming and T. M. Susemihl, Assrs. to National Aniline and Chemical Co. U.S.P. 1,363,886, 28.12.20. Appl., 1.7.19.

CLAIM is made to a disazo dye having the formula, $(4)NH_2{\cdot}C_6H_4{\cdot}N{:}N{\cdot}(2)C_{10}H_3(1\text{-}OH,8\text{-}NH_2,5\text{-}SO_3H)(7)N{:}N{\cdot}C_6H_4{\cdot}(4)NH_2$, which yields *p*-phenylenediamine and triamino-8-naphthol-4-sulphonic acid on reduction with stannous chloride and hydrochloric acid, and dyes cotton, wool, and natural or artificial silk, greenish shades of black which can be developed on the fibre. —L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

"Ashi" fibre; Microscopical examination, chemical composition, and reactions of ——. M. Ishikawa. Kôgyô Kwagaku Zasshi (J. Chem. Ind. Tokyo), 1920, 23, 1153—1157.

"ASHI" reed fibre resembles straw in regard to the kind of cells, chemical composition, and reactions. It gave the following analytical results: Moisture 11·2%, water-soluble matter 3·78%, ash 1·24%, fat and wax 0·96%, lignin 14·7%, cellulose 49·8%, and pectin etc. 18·32%.—K. K.

Mechanical wood pulp; Determination of ——. M. G. Kotibhasker. J. Soc. Dyers and Col., 1921, 37, 11—13.

THE absorption of *p*-nitraniline by mechanical wood pulp is constant under defined conditions, experiment indicating that pure mechanical wood pulp in thin slices treated with the reagent in the proportion of 2 g. to 40—60 c.c. of an approximately 0·1% solution in dilute hydrochloric acid shows in 6—24 hrs. a constant absorption of 0·56—0·57%. The excess of *p*-nitraniline is determined by adding a known excess of titanous chloride to an aliquot portion of the solution, say 10 c.c., boiling to effect reduction, and titrating back the excess of titanous salt with standard solution of iron alum. By this means the mechanical wood in an unknown sample can be determined with an error of not more than about 2%. The absorption of *p*-nitraniline by jute also shows a constant figure of 0·35—0·37%. —G. F. M.

Sulphite-cellulose waste liquors; Extraction of —— with ether and benzene. B. Holmberg. Svensk Kem. Tidskr., 1920, 32, 56—67. Chem. Zentr., 1920, 91, IV., 753.

THE extraction of sulphite liquors with ether yields a tarry substance and a white crystalline compound, termed sulphite liquor lactone, $(C_9H_4O_2.OCH_3)_2$. The latter forms square plates or flat prisms, m.p. 250°—255° C., $[\alpha]_D = -192°$ (in acetone at room temperature), soluble in ether, alcohol, and methyl

alcohol, very soluble in acetone, but only slightly soluble in water. Sulphuric acid converts the lactone into a monosulphonic acid; on subsequent treatment with water a hydroxy-acid is formed. The lactone is only slowly dissolved by sodium carbonate solution, but is readily soluble in sodium or potassium hydroxide, from which it is precipitated by carbon dioxide. The hydroxy-acid has the formula $C_{17}H_{12}(OH)_3(OCH_3)_2CO_2H$; $[\alpha]_D = +280°$ (in acetone at normal temperature). The lactone combines readily with diazonium salts in alkaline solution. It is probably the lactone of diguaiacoltetramethylcarbinolcarboxylic acid.
—W. J. W.

Sericin. Türk. *See* XIXA.

Adsorption by cellulose. Kolthoff. *See* XXIII.

Patents.

Textile fibres; Process of producing ——. R. A. Marr. U.S.P. 1,362,723, 21.12.20. Appl., 26.3.17. Renewed 10.5.20.

Plant structures containing fibrous material are digested with a solution of a zinc salt, the digestion being stopped before the binding substances which hold the fibres together as filaments are attacked.
—A. J. H.

Woody constituents of vegetable fibres; Process for removing —— *by carbonising.* Deutsche Wollentfettung A.-G. G.P. 325,885, 1.3.19.

The material is immersed in dilute acid, after which it is rinsed with cold water before drying by heat. Bast fibres absorb the acid more readily than woody constituents, but also give up the absorbed acid more easily on washing. For the treatment of flax and hemp combings and waste derived from the spinning of bast fibres, sulphuric acid of 1° B. (sp. gr. 1·007) is effective.—W. J. W.

Cellulose solutions; Process for preparing ——. Z. Ostenberg. U.S.P. 1,355,415, 12.10.20. Appl., 1.11.16.

Cellulose is dissolved in a mixture of calcium chloride with sulphuric acid of more than 60% strength.—A. J. H.

Cellulose or the like; System for the treatment of ——. R. A. Kocher. U.S.P. 1,362,875, 21.12.20. Appl., 27.2.17.

The apparatus consists of a container, into which halogen acid gas may be forced under pressure, and provided with means for agitating and varying the temperature of the material therein. Means are also provided for removing the halogen acid gas and halogen acid solution from the container, for separating these and for returning the halogen acid solution, independently of the halogen acid gas, for the treatment of the material.—A. J. H.

Acetate of cellulose; Manufacture of solutions, compositions, or preparations having a basis of ——. H. Dreyfus. U.S.P. 1,363,763, 28.12.20. Appl., 7.7.19.

See E.P. 131,669 of 1918; J., 1919, 834 A.

Semi-cellulose; Method of manufacture of ——. T. and E. Kittelsen. U.S.P. 1,365,039, 11.1.21. Appl., 5.4.19.

See G.P. 324,053 of 1919; J., 1920, 779 A.

Paper-making machines. Process Engineers, Inc., Assees. of W. E. Metcalf. E.P. 145,440, 18.6.20. Conv., 9.3.15.

Paper pulp reclaimers. C. S. Bird. E.P. 146,891, 6.7.20. Conv., 21.1.15.

Removing fibrous material from the bottom of [pulp] digesters used in paper making. W. M. Wallace. E.P. 156,025, 10.3.20.

Cellulose. G.P. 300,703. *See* XXII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Patents.

Dyeing raw fibrous stock; Method for ——. P. MacIntyre. U.S.P. 1,355,797, 12.10.20. Appl., 15.9.19.

The raw material in bulk is treated with a dye liquor, and the dye is then oxidised by forcing an oxidising agent through the mass.—A. J. H.

Washing and drying clothes; Process for ——. A. R. Willford, Assr. to The Electric Ozone Co. U.S.P. 1,362,658, 21.12.20. Appl., 8.3.17.

At all stages in the washing process (washing, water extracting operation, mangling, and tumbling and shaking operations) the clothes are subjected to the action of ozone, and they are afterwards dried in a room containing ozonised air.
—A. J. H.

Bleaching agent. E.P. 147,535. *See* VII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Nitrites and nitrates; Reduction of ——. O. Baudisch and P. Mayer. Biochem.-Zeits., 1920, **107**, 1—43.

Nitrites are reduced quantitatively by excess of ferrous hydroxide in neutral and alkaline solution. In boiling solutions made alkaline with carbonates, nitrous oxide and ammonia are chiefly formed. In boiling caustic alkali solution the nitrite is reduced quantitativly to ammonia. Alkali nitrates are reduced quantitatively to ammonia by ferrous hydroxide in neutral solution and in alkaline solution containing 28% of sodium hydroxide. Starting with neutrality the amount of nitrate reduced diminishes with addition of alkali until the alkali content is 6·5% NaOH when a minimum is reached; beyond that limit the amount reduced increases with the increase of alkali until the maximum is reached at 28% NaOH. Up to a concentration of 6·5% NaOH the presence of oxygen is necessary for the reduction with ferrous hydroxide. With higher alkali concentrations reduction also takes place in the absence of oxygen. Up to an alkali concentration of 6·5% NaOH the amount of nitrate reduced is proportional to the amount of oxygen present in solution or absorbed by the ferrous hydroxide. The above observations may be utilised for the estimation of nitrites and nitrates separately and when together.—S. S. Z.

Salts; Double decompositions of —— *and the phase rule.* E. Rengade. Comptes rend., 1921, **172**, 60—62. (*Cf.* J., 1917, 961.)

In a discussion of Raveau's work (J., 1920, 819 A) the author considers the effect of the addition of a small amount of water to a mixture of sodium nitrate and ammonium chloride and shows that at the ordinary temperature there are only two ternary mixtures, $NaNO_3$—NH_4NO_3—NH_4Cl and $NaNO_3$—NH_4Cl—$NaCl$, which can exist without change in contact with a small amount of water. All other mixtures of the two, three, or four salts containing the four ions will decompose giving,

according to the conditions, one or other of the ternary mixtures mentioned.—W. G.

Hydrogen cyanide; Detection of —— in air. A. Sieverts and A. Hermsdorf. Z. angew. Chem., 1921, 34, 3—5.

FILTER-PAPER is dipped in a solution of copper acetate and benzidine acetate and then exposed in the atmosphere to be tested; a blue colour appears on the paper within 7 secs., if the air contains more than 15 mg. of HCN per cb. m. The copper acetate solution (2·86 g. per l.) and benzidine acetate solution (475 c.c. of cold saturated benzidine acetate solution and 525 c.c. of water) are kept separately and equal volumes are mixed immediately before use.—W. P. S.

Hydrogen arsenide; Preparation of —— of high purity, and its quantitative determination. H. Thoms and L. Hess. Ber. Deuts. Pharm. Ges., 1920, 30, 483—489.

PURE hydrogen arsenide is conveniently obtained by the action of water or acids on calcium arsenide, and the difficulty and danger of preparing this latter substance can be entirely obviated by adding a neutral diluent such as sand (5·5 kg.) to the mixture of powdered arsenic (3·1 kg.) and coarse calcium filings (2·4 kg.). The mixture is placed in a sheet iron container enclosed in a second vessel, and ignited by means of a mixture of potassium chlorate and magnesium. The mass glows intensely, but no flame and but little arsenious oxide is produced. The arsenide is removed when cold and ground to a coarse powder which may then be used instead of sand as diluent in the same proportion in succeeding preparations. The evaluation of calcium arsenide is carried out in a nitrometer charged with brine, the hydrogen arsenide being absorbed from the evolved gas by cupric chloride solution. Calcium arsenide prepared as above gives about 37—38% of hydrogen arsenide containing about 0·004% by weight or 14% by vol. of hydrogen. The remainder of the arsenic in the metallic arsenide appears as a brown powder (probably solid hydrogen arsenide) in the reaction vessel. Aqueous solutions of hydrogen arsenide undergo rapid decomposition with the formation of metallic arsenic which remains in colloidal solution. The decomposition can be followed by titrating the solution with $N/100$ iodine, when the arsenide is oxidised first to arsenious acid, and then, if the solution is rendered alkaline with a bicarbonate, to arsenic acid in the usual way. (*Cf.* J.C.S., Feb.)—G. F. M.

Bromine; Technology of ——. W. Hüttner. Chem.-Zeit., 1921, 45, 49—51.

A DESCRIPTION of methods used for the manufacture of bromine; the general process consists in the decomposition of bromides by chlorine (*cf.* Kubierschky, J., 1914, 135), but the electrolytic process is used in a few works. In Germany, the production of bromine rose from 7500 kg. in 1867 to 866,000 kg. in 1911; during the same period, the production in America increased from 5000 to 3,236,000 kg.—W. P. S.

Ammonia. Franks. *See* IIA.

Mercuric chloride and lead salts. Sasse. *See* XXIII.

PATENTS.

Bleaching and disinfecting agents; Production of ——. G. Kereszty and E. Wolf. E.P. 147,535, 3.3.20. Conv., 12.7.19.

A MIXTURE of 1 pt. of basic magnesium hypochlorite and 3 pts. of sodium bicarbonate, which is stable in the dry state, yields a solution which after 10 mins. contains 50%, and after 4 days 90% of the active chlorine of the hypochlorite. The slow decomposition compensates for the loss of chlorine on standing, and the mixture thus gives a solution of which the chlorine content is maintained better than in the case of other bleaching agents.—C. I.

Alkali-metal compounds; Process of producing water-soluble —— from water-insoluble substances. H. S. Blackmore. U.S.P. 1,355,381, 12.10.20. Appl., 19.3.17.

INSOLUBLE minerals containing alkali compounds are treated with a non-acid silicofluoride.—C. I.

Alkali-metal compounds; Process of producing water-soluble —— from water-insoluble substances. H. S. Blackmore, Assr. to Kali Co. of America. U.S.P. (A) 1,355,588 and (B) 1,355,794, 12.10.20. Appl., 14.12.18.

(A) SILICATES containing potassium are exposed to the action of a silicofluoride of a metal of the iron group, whereby the potassium is converted into a compound soluble in hot water. (B) Alkali compounds are extracted from insoluble silicates by exposing them to the action of an alkali silicofluoride, separating the resulting soluble product and treating it with a chemical reagent to produce a still more soluble alkali compound.—A. R. P.

Alkali-metal salt mixtures; Process of treating ——. J. A. Cullen. U.S.P. (A) 1,363,091 and (B) 1,363,092, 21.12.20. Appl., 26.3.19.

(A) IN potassium-salt mixtures containing carbonates, the latter are precipitated, and a soluble sulphate is added to the solution in excess of the amount required to combine with the potassium which is not already united to the sulphate radicle. (B) After precipitating the carbonates with lime, a soluble haloid salt is added to furnish the acid radicle for the potassium. In both cases the potassium salt is recovered by concentration and crystallisation.—W. J. W.

Hydrocyanic acid; Process of recovering ——. G. H. Buchanan, Assr. to American Cyanamid Co. U.S.P. 1,355,384, 12.10.20. Appl., 12.11.19.

AN impure cyanide containing 40% of calcium chloride and 15% of lime is made into an emulsion with water, treated with a dilute mineral acid, and heated.—C. I.

Salts; Process for decomposing —— in pans. F. Brandenburg. G.P. 324,259, 27.10.17.

IN the working of spent pickle liquor to ferric oxide, the decomposition vessel is charged with previously prepared ferric oxide, heated, and the spent liquor then added gradually and continuously with constant stirring. A similar process is applicable to the treatment of waste liquors containing ferrous sulphate, magnesium chloride, sodium bisulphate, etc.—A. R. P.

Sulphur; Purification of ——. J. J. Hood. E.P. 155,692, 25.10 and 17.11.19.

A SOLUTION of sulphur in carbon bisulphide, such as that obtained from spent oxide, is purified by agitation with 1—2% by vol. of sulphuric acid (sp. gr. 1·8), whereby a considerable quantity of tarry matter is precipitated. The mixture is then, either before or after filtration, agitated with 5—10% by vol. of water and the aqueous layer containing the impurities removed. Finally, the sulphur solution is filtered through alumina or bauxite and the carbon bisulphide evaporated, leaving a residue of pure sulphur.—A. R. P.

Hydrogen; Process for producing ——. R. H. Uhlinger. U.S.P. 1,363,488, 28.12.20. Appl., 20.4.20.

A HYDROCARBON heated to 500°—900° C. is intro-

duced into a decomposition chamber maintained at 1100°—1300° C.—L. A. C.

Nitric acid; Production of concentrated nitrous gases and ——. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. E.P. 137,071, 24.12.19. Conv., 21.10.16.

VIII.—GLASS; CERAMICS.

Silica glass; Double refraction and crystalline structure of ——. Lord Rayleigh. Proc. Roy. Soc., 1920, A, 98, 284—295.

GLASSES in general have no double refraction, except that due to bad annealing, but silica glass shows weak double refraction (about 1/60th that of crystalline quartz), which can only be accounted for by accepting that the glass has a crystalline structure. In a mass of silica which has been melted, but not drawn or blown, the structure consists of doubly refracting grains, with dimensions about 0·5 mm., oriented at random. The grains are very persistent and individually survive a re-melting of the material. If the grained material is drawn out while soft, the grains are elongated into crystalline fibres or ribbons. These fibres always give "straight extinction" in the polariscope, and their length is along one axis of the ellipsoid of optical elasticity, but apparently not always along the same axis. If the material is bent or twisted, the fibres follow its course unbroken, and are always extinguished in the polariscope if the nicols are set along the tangent and normal to their direction at any point. Fused silica sometimes contains isolated small inclusions of quartz, with angular outlines, which have escaped vitrification. These are conspicuous in the polariscope by the strain effects they produce in the surrounding glass.—J. F. S.

Refractory materials used in coke-oven construction; Properties of ——. W. C. Hancock. Iron and Steel Inst., Carnegie Scholarship Mem., 1920, 41—63.

TEST-PIECES were made of Stourbridge clay mixed with varying proportions of "grog" made from the same clay fired to about 1400° C., sometimes with the addition of ganister to increase the silica content. An abrasion test was devised in which one test-piece was rigidly fixed whilst another was caused to pass backwards and forwards over its surface. When both surfaces had the same composition the abrasion was the same for both. Clay surfaces without grog showed least abrasion. Fine-grained surfaces suffered less abrasion than coarse-grained, whether the coarser grain was due to an increase in quantity or size of the grog. Increasing the size of the grog particles tended to decrease the porosity and increase the density. Tests on permeability to air at ordinary temperatures showed a decreasing permeability as the proportion of grog was increased, and also a decreasing permeability as the particles became finer. A few heat expansion tests were made with the following results: Clay, 0·33% at 750° C., 0·70% at 950° C., and 0·74% at 980° C.; mixture of 80% of clay and 20% of 30-mesh grog, 0·34% at 800° C. and 0·47% at 900° C.; mixture of 60% of clay and 40% of ¼ in.-mesh grog, 0·40% at 860° C. and 0·46% at 990° C. The presence of soluble salts in coals has a great influence on the life of the lining of coke ovens. By washing the coal with water a certain proportion of the salts can be removed, according to the size of the particles and the method of washing. Thus with three coals, ground to pass a 1/16 in-mesh sieve, 49%, 48%, and 73% respectively of the soluble salts were removed by treatment with warm water on a hot plate for 8 hrs. No relation between the chlorine content and total salt content of different coals could be established. By heating fireclay with coal at 1450° C. the alkali content of the fireclay was considerably increased when unwashed coal was used, the increase being less with washed coal. The presence of moisture appeared to favour the incorporation of alkali into the refractory.—E. H. R.

Clays; Effect of aluminium chloride upon ——. H. P. Reinecker and J. S. George. J. Amer. Ceram. Soc., 1920, 3, 994—996.

INCREASING amounts of aluminium chloride, varying from 0·05 to 0·5% of the dry weight of the clays, were added to North Carolina and Georgia kaolins and to Tennessee ball clay No. 5. In a subsequent series of experiments sufficient ammonia was added to precipitate the alumina. The mixtures were made into briquettes and bars, and the water of plasticity, drying shrinkage, and modulus of rupture in the dry state determined. Aluminium chloride, with or without ammonia, did not noticeably affect the plasticity, the greatest change being observed with 0·4 and 0·5% Al_2Cl_6+ammonia. The addition of aluminium chloride reduced the drying shrinkage of the two kaolins, but the ball clay showed alternate phases of reduced and increased shrinkage, as also did the kaolins in presence of aluminium chloride with ammonia. The only clay which showed a marked increase in strength in the dry state after adding aluminium chloride was the Carolina kaolin, and this effect was destroyed by ammonia; the dry strength of the ball clay was decreased by aluminium chloride. These effects are attributed to the aluminium chloride in solution and to the acidity produced by its dissociation. If larger amounts of aluminium hydroxide are present, there may be a gain in strength due to the colloidal precipitate formed.—A. B. S.

Clay; Influence of grog in admixture with ——. W. C. Hancock. Trans. Ceram. Soc., 1919-20, 19, 149—152.

SMALL test-pieces were moulded both from a neat Stourbridge plastic clay and also from the clay mixed with grog, and were weighed at once. After drying in the air and in an oven at 105° C. they were again weighed, and the amount of tempering water thus determined. Less water was required when grog was present than for the neat clay. The amount of tempering water decreased as the percentage of grog of a particular grade increased, but increased when finer-grained grog replaced the coarser grog. In another set of experiments it was found that the finer the grog the more water was attached to it, but the amount of water attached to a particular grade seemed to diminish as the ratio of grog to clay increased. The discrepancy between the figures in the two cases was attributed to the latter mixtures being less thoroughly worked and stored for a much shorter time before moulding than the former.—H. S. H.

Contraction of some quaternary [ceramic] mixtures fired to different temperatures. H. S. Newman. Trans. Ceram. Soc., 1919-20, 19, 132—139.

SLABS were prepared from ball clay, china clay, stone, and flint in varying proportions, and some of each batch were fired in a saggar to cones 1a, 6a, and 8. Half were then dipped in a lead glaze and half in a leadless glaze and fired to cone 3a. The contraction at cone 016 was less in the majority

of cases than the dry contraction, showing that at a certain temperature there is an expansion, probably due to the liberation of combined water. Until the proportion of stone to flint falls below 3:2 the replacing of ball clay by china clay raises the contraction, and after this proportion is passed the reverse action takes place at the temperature of cone 1a. For cones 6a and 8 the proportion of stone to flint must be below 2:3 before the reversion occurs. The contraction does not always rise with the temperature, but with some mixtures it reaches a maximum and then falls again. The gradual substitution of one clay for the other, with the other materials remaining constant, does not have a direct bearing on the contraction, nor does the change from stone to flint whilst keeping the clays constant. A large variation may be made in the proportions of ingredients used without affecting the working properties or causing crazing or peeling.—H. S. H.

Porcelain body; Time and temperature of burning as factors influencing the constitution and microstructure of ——. A. A. Klein. J. Amer. Ceram. Soc., 1920, **3**, 978—983.

FURTHER results, confirming those in a previous paper (J., 1916, 1220; *cf.* Mellor, J., 1917, 550), are given to show the effect of high temperatures in determining the constitution and microstructure of porcelain. Several samples of green table ware were burned at cone 13—14 (1348° C. by pyrometer) with a soaking period of 12—18 hrs., some of the samples being re-fired five times, *i.e.*, with soaking periods varying from 12—18 hrs. to 72—108 hrs. One sample was fired in a pot-furnace to cone 15 for 1 hr. After one firing the felspar had melted completely, the kaolin had completely dissociated, forming amorphous sillimanite and an extremely small amount of fine crystalline sillimanite, and the solution of quartz was insignificant. After six firings there was a small increase in the amount of crystalline sillimanite and a decrease in the amount of quartz from 30 to 15%, the quartz grains being gradually rounded by solution. The sample fired for 1 hr. at cone 15 contained no amorphous sillimanite, but relatively large crystals of that mineral. Only the larger quartz crystals remained, these being well rounded, and only 6% of free quartz was left. The results show that, for the particular body used, the actual temperature of burning has a much more marked effect than the time of soaking on the constitution and structure of the porcelain.
—A. B. S.

Lime in earthenware bodies. A. Heath and A. Leese. Trans. Ceram. Soc., 1919-20, **19**, 93—105.

PLATES were made from a body consisting of ball clay (30), china clay (25), flint (30), stone (8·25), and whiting (6·75%), and fired in a works kiln. The lime and stone were ground together. The loss from crooked, cracked, etc. ware was less than for ordinary earthenware fired at the same time. On treating with ordinary glaze and firing, the plates all crazed, harder firing producing worse effects. The contraction was less than for the body without lime, so that the lime does not act as a flux at the temperature reached. No sign of crazing was found (even when the whole of the stone was replaced by whiting) on using a glaze of the composition, (K_2O 0·047, Na_2O 0·267, CaO 0·449, PbO 0·237), 0·533 Al_2O_3, (4·3 SiO_2, 0·983 B_2O_3).—H. S. H.

Ceramic ware; New method for use in firing ——. K. M. Balley. Chem.-Zeit., 1921, **45**, 75.

HOT filtered air or other gas is passed into saggers or muffles so as to maintain a pressure of about 5 mm. water column therein, air or oxygen being used for oxidising, nitrogen or carbon dioxide for neutral, and hydrogen or carbon monoxide for reducing atmospheres. By this means coal of any kind may be used, as sulphurous fumes etc. cannot reach the goods.—A. B. S.

Aventurine glazes. H. G. Schurecht. J. Amer. Ceram. Soc., 1920, **3**, 970—977.

GLAZES of the composition 0·4 Na_2O, 0·6 PbO (0·05 Al_2O_3, 0·25 B_2O_3, 0·12—0·81 Fe_2O_3), 2·4—4·2 SiO_2 were applied to white ware fired to cone 4 under oxidising conditions. The best crystalline glazes were obtained when more than 0·41 Fe_2O_3 was employed in glazes with 2·4 SiO_2, and more than 0·58 Fe_2O_3 in glazes with 4·2 SiO_2. A variety of colours from red to brown and black may be obtained by varying the kiln atmosphere from oxidising to reducing, but if the ware is not protected in saggers the glazes become dull black owing to the formation of a ferrous lustre. If such dull glazes are covered with a suitable raw lead glaze and fired in an oxidising atmosphere, a maroon colour is obtained. The size of the crystals and the refractoriness of the glaze are increased by increasing the iron content and by slow cooling.

IX.—BUILDING MATERIALS.

Gypsum products [plaster]; Results of testing ——. W. E. Emley and C. F. Faxon. J. Amer. Ceram. Soc., 1920, **3**, 984—993.

FORTY-THREE samples made by three different manufacturers were tested according to the specification of the Amer. Soc. for Testing Materials C—26—19 T. The results of chemical analyses, calculated to $CaSO_4,\frac{1}{2}H_2O$, usually showed an excess of lime or sulphuric acid, indicating the presence of foreign material. The normal consistency or number of c.c. of water required to be added to 100 g. of dry material to produce a paste of standard " wetness " (*i.e.*, such that the final radius of the pat in a Southard viscosimeter was 9·6 cm.) was determined. The time of set was measured by means of a Vicat needle; the temperature-rise method was found to be misleading, whereas the Vicat needle gave definite results. The fineness was determined by passing the dry material through Nos. 8 and 14

sieves, and washing it with kerosene through Nos. 28, 48, 100, and 200 sieves. The compressive strength was determined on 3 cylinders, each 2 in. diameter and 4 in. high, made of paste of normal consistency, removed from the moulds as soon as stiff enough to handle, and stored in a room for a week before testing. The yield of plaster was estimated by weighing the moulds when empty and again immediately after filling; the cylinders were also weighed just before crushing, and the weight per cb. ft. of paste, the weight of dry material per cb. ft. of paste, and the weight per cb. ft. of set material were calculated. The tensile strength was determined on briquettes of the usual form made and stored like those used for the compression test. The averages of the results obtained are:—

Character of sample.	Degree of fineness.			Compressive strength, lb. per sq. in.	Tensile strength, lb. per sq. in.	Consistency.	lb. set matter per cb. ft.	Time of set, mins.
	On 100 sieve.	100-200.	Through 200 sieve.					
Calcined gypsum	10·1	14·5	75·1	1665	325	58	80	13
do. +retarder ..	10·5	13·1	76·3	1010	215	61	76	6 : 41
do. +retarder+fibre ..	11·0	15·9	73·2	1115	278	56	79	14 : 39
do. +retarder+wood fibre ..	20·3	13·5	66·4	835	214	57	79	9 : 11
do. +retarder+sand ..	64·4	10·2	25·2	335	80	25	109	2 : 30
do. +retarder+fibre+sand ..	64·0	8·7	27·3	415	96	26	106	3 : 23

The compressive strength = tensile strength × 4·6. The tensile strength = gypsum content × 5·3.

—A. B. S.

Patent.

Building block. F. J. Kramer, Assr. to J. Whitaker. *U.S.P. 1,363,045, 21.12.20. Appl., 25.5.20.*

A building material consists of furnace slag pulverised and compounded with cement, together with potassium permanganate and hydrofluoric acid.

—H. S. H.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Steels; Relation of heat-treatment to cold-work in hypo-eutectoid and eutectoid ——. A. T. Adam. Iron and Steel Inst., Carnegie Scholarship Mem., 1920, 65—127.

The experiments described were undertaken to study the processes used in wire-drawing practice, and were confined to this form of cold-work. Most of the experiments were carried out on two steels, one a basic open-hearth steel containing C 0·44%, Si 0·06%, Mn 0·82%, S 0·036%, P 0·031%; the other an acid open-hearth Swedish steel containing C 0·85%, Si 0·12%, Mn 0·30%, S 0·022%, and P 0·02%. To determine the effect of heat treatment in preparation for cold-work the steel, in the form of 4 or 5 S.W.G. rod, was heated to 850°, 950°, or 1050° C, and then cooled in air or quenched in lead at 500° or in oil and reheated to 600° C. In the case of the basic open-hearth steel the capacity to withstand cold-work increased with the temperature with air-cooling. With lead quenching lower temperatures gave better results, but the differences due to temperature were so slight that it may be concluded that the safe working range of temperature in the "patenting" process is extremely wide. Experiments with other steels confirmed this, and indicated that one of the objects of "patenting" is to enlarge the grain rather than to refine it. A good wire is produced from what would normally be an over-heated steel. With steel of eutectoid composition, *i.e.*, of about the composition of the above Swedish steel, there is no advantage in "patenting" beyond 950° C. The improvement obtained by quenching in lead is more marked in these steels than in medium steel. Heating below the critical range does not remove the effects of previous cold-work and cannot replace "patenting." Experiments on the effect of heat treatment after cold-work showed that hot galvanising has a bad effect on the physical properties of the wire, and the higher the tenacity of the wire, the more serious is the effect. Time is an important factor, especially as regards its influence on the maximum load. The temperature of the galvanising bath should be as low as possible and the immersion should be as short as possible, consistent with the production of a satisfactory coating of zinc. The work on the microstructure showed that a fine-grained structure is unsuitable for wire-drawing. The most suitable structure is one in which the grains are large enough to elongate into fibres and which consists throughout of granular or cellular sorbite. A structure of laminated pearlite, as in annealed eutectoid steels, is unsuitable. The structural effects of heat treatment after cold-work are scarcely visible until recrystallisation commences. *When this occurs the ferrite forms new grain boundaries and the cementite collects* in the form of nodules which tend to coalesce.

—E. H. R.

Passivity. Researches on iron and nickel. C. A. Lobry de Bruyn. Rec. Trav. Chim., 1921, **40**, 30—64.

The author finds for the equilibrium potential of iron in ferrous sulphate solution, when compared against a calomel normal electrode the value $E_H = -0·434$ volt. In connexion with the anodic polarisation of iron a graph is given showing the variation in the potential of iron electrodes in solutions of ferrous sulphate and ferrous chloride respectively as measured against a calomel electrode at different current densities. In ferrous sulphate solution when the current density reached about 0·4 ampère per sq. cm., the electrode suddenly became passive and any further increase in current density only resulted in a very feeble increase in potential. In ferrous chloride solution this sudden change was not observed, and even at the highest densities used the electrode remained active. In the passage into solution from an iron anode the current yield is practically 100% when the iron is in the active state. When, however, it is in the passive state the yield is only of the order of 1% and varies with the sample of iron used. The potential of passive iron during anodic polarisation falls as the temperature rises, and curves are given showing the activation of iron under different conditions after anodic polarisation.—W. G.

Manganese steel; Magnetic mechanical analysis of ——. R. Hadfield, S. R. Williams, and I. S. Bowen. Proc. Roy. Soc., 1920, A, **98**, 297—302.

Rods of manganese steel containing C 1·25%, Si 0·43%, and Mn 12·20%, when heated to 1000° C. and quenched in cold water, do not exhibit the Joule effect, that is they do not lengthen when subjected to a magnetic field, nor do they exhibit the Vilari effect, that is, change their intensity of mag-

netisation when under tension. A slight magnetic susceptibility is exhibited if the oxide skin is not removed, but when this is removed the bars have no susceptibility. Similar bars which have been subjected to a double annealing process (heated in welded iron tubes to 550° C., allowed to cool to 450° C. in 8 hrs., and then heated at 500° C. for 60 hrs.), exhibit both the Joule and the Vilari effects. The increase in length is continuous with fields varying from zero to 3000 gauss, and with the last-named field amounts to 82×10^{-4} cm. The intensity of magnetisation increases with the application of tension for all fields up to 3000 gauss. —J. F. S.

Iron and uranium; Alloys of ——. E. P. Polushkin. Iron and Steel Inst., Carnegie Scholarship Mem., 1920, 129—150. (*Cf.* J., 1920, 692 A.)

Ferro-uranium was made in an electric arc furnace lined with a mixture of U_3O_8 and pitch, and having a water-cooled bottom. The charge consisted of uranium oxide, petroleum coke, and steel turnings with fluorspar added to form a slag. The alloys used for making uranium steel generally contain 35—45% U and 1—5% C, but alloys containing up to 90% U were prepared and examined. The alloys are generally well crystallised, are hard and pyrophoric, especially those containing higher proportions of uranium. Alloys with a high silicon (16—18%) and low carbon content are not pyrophoric, even when containing as much as 40% U. The specific gravity varies from 7·34 with 4·13% U to about 12·0 with 90·0% U. The melting points could not be determined with accuracy on account of oxidation of the uranium, but in the case of alloys with 28·7% and 55·2% U the m.p. was in the neighbourhood of 1540°—1660° C. in the first case and 1660°—1785° C. in the second. The alloys containing more than 40% U are decomposed by water; alloys with 40—55% U are only decomposed if their carbon content is less than 3%, but not lower than 0·7%, but alloys with 85—90% U are decomposed though their carbon content may vary from 1·2 to 7·4%. Ferro-uranium dissolves very readily in steel and becomes uniformly distributed, whether added in the furnace or in the ladle. The recovery is best when the ferro-uranium is added in the ladle. In all uranium steels part of the uranium is present as oxide. The microstructure of the ferro-uranium alloys is very complex, since five components are always present, iron, uranium, carbon, vanadium, and silicon. From the study of a series of fifty alloys the following constituents were recognised and their composition established: Metallic uranium (gamma), carbide UC (alpha), double carbide Fe_3C,U_2C_3 (iota), carbide U_2C_3, double carbide of alpha and iota, Fe_5U (beta), and U_3O_8. In addition, three conglomerates of eutectic character were found—gamma+ferrite, alpha+ferrite, and beta+Fe_3C. The constituents containing no uranium are ferrite, pearlite, V_2C, FeSi, and graphite. The following table gives the principal types of microstructure:—

Main components.	Uranium. %	Carbon. %
Fe_5U+uranium+ferrite	54—39	0·18—1·13
Fe_5U+UC+ferrite	31—28	0·34—0·83
Ferrite+UC	20	1·10
Ferrite+Fe_5U	17—5	0·53—0·76
Ferrite+pearlite+UC (steels) ..	7—0·20	0·20—0·50
Fe_3C, U_2C_3+pearlite+FeSi ..	45—33	4·30—5·0
Fe_3C, U_2C_3+Fe_5U+FeSi ..	64—48	4·90—6·1
UC+Fe_3C, U_2C_3+Fe_5U+ferrite ..	46—41	2·30—3·50
Fe_5U+Fe_3C+pearlite	17—4	3·0—4·3

Neither uranium nor any of its compounds mentioned above forms a solid solution with iron. The carbide UC does not dissolve in iron even at 1200°—1250° C. The affinity of vanadium for carbon is greater than that of uranium.—E. H. R.

Aluminium; Density of —— *from 20° to 1000° C.* J. D. Edwards and T. A. Moormann. Chem. and Met. Eng., 1921, 24, 61—64.

The density of annealed aluminium (99·75% Al) was found to be 2·703 g. per c.c. at 20° C., and that of liquid aluminium at its melting point (658·7° C.) 2·382, while at higher temperatures the density is given by the equation $D=2·382-[0·000272(t-658)]$. Tables are given showing the density of molten aluminium of different degrees of purity at various temperatures up to 1000° C. The shrinkage of solid aluminium from 658° C. to room temperature was found to be 0·21 in. per ft., while the shrinkage which takes place on solidification is approximately 6·6%. (*Cf.* J.C.S., Feb.)—A. R. P.

Cadmium; Production of electrolytic ——. H. R. Hanley. Chem. and Met. Eng., 1920, 23, 1257—1264.

A product from the bag-house of a copper smelting plant, containing approx. 0·55% Cd, 19% Zn, and 6·6% As, besides other metals, was leached with sulphuric acid, and a solution obtained, containing Zn, 96·0; Cu, 8·0; Cd, 5·0; Fe, 2·0; Mn, 0·04; As, 0·5; Co, 0·015; and Ni, 0·012 g.p.l., with traces of Bi, Tl, and Te. Treatment of this solution with powdered limestone, under air agitation, precipitated iron and traces of arsenic, and 40% of the copper, and by addition of zinc, a copper-cadmium-zinc mud, with 25% Cu, 25% Cd, and 30% Zn, was obtained which was employed as raw material for production of cadmium. The wet mud was leached with dilute sulphuric acid at 60° C., after which limestone, and then hydrated lime, were added to neutralise acidity, and the copper residue was separated. Cadmium was precipitated from the filtrate as a voluminous sponge on zinc sheets, and this, after washing, was dissolved in spent cadmium electrolyte. Iron and thallium must be removed from this solution by means of hydrated lime and sodium bichromate, respectively. When the original copper-cadmium-zinc mud contained arsenic, the zinc-cadmium solution was treated with ferric sulphate before precipitation of the cadmium sponge. For the electrolysis of the cadmium solution, double anodes of semi-circular shape were found suitable, and rotating disc cathodes of aluminium were employed. Impurities in the electrolyte must be avoided as they give rise to formation of sponge and "trees" in the cadmium deposit, and further tend to cause its corrosion. The deposited cadmium was melted under heavy oil and cast into bars, and these were re-melted under caustic soda and cast to form sticks. Cadmium has found application in the manufacture of solder, and, as a rust-preventive coating, is superior to nickel.—W. J. W.

Hydrogenating metals; Preparation of active ——. A. Brochet. Bull. Soc. Chim., 1920, 27, 897—898.

An activated nickel may readily be prepared by heating certain of its organic salts, *e.g.*, the formate to 200°—250° C. or the oxalate to 320°—380° C. So prepared the nickel is not spontaneously pyrophoric in the air at the ordinary temperature. Active cobalt and iron may be similarly prepared.—W. G.

Zirconium minerals; Analysis of ——. H. V. Thompson. Trans. Ceram. Soc., 1919-20, 19, 153—157.

The mineral is fused with pure sodium peroxide in a nickel crucible; after decomposition of the melt with water the residue contains all the iron, titanium, and zirconium oxides, together with some of the silica, while the whole of the alumina and

the remainder of the silica are contained in the filtrate. Analytical details are given for the separation.—H. S. H.

Patents.

Alloy of iron; Rust-resisting ——. G. H. Charls. U.S.P. 1,363,564, 28.12.20. Appl., 30.6.20.

Iron is alloyed with small amounts of copper and molybdenum.—B. M. V.

Iron; Rust-resisting alloy of ——. *Method of enhancing rust-resisting qualities of iron.* G. H. Charls. U.S.P. (A) 1,355,589 and (B) 1,355,590, 12.10.20. Appl., 7.4.20.

(A) A rust-resisting iron alloy contains a small amount of molybdenum and not more than 0·2% C. (B) The rust-resisting properties of iron are enhanced by adding to the molten metal not more than 1% Mo.—A. R. P.

Tungsten powder; Method for the production of metallic —— *direct from sodium and potassium tungstates.* C. J. Head. E.P. 155,600, 13.10.17.

Finely ground sodium tungstate is mixed with ammonium chloride or any chloride of the iron or manganese group and a suitable reducing agent, *e.g.* wood charcoal, anthracite, or, preferably, sawdust. The mixture is heated in a tall nickel-chromium crucible, made in sections and set in a brick-lined, iron-sheathed furnace, at 850°—950° C. for 3—5 hrs., or until all the ammonia has been expelled. The lower half of the crucible, containing the charge is then removed and heated to 1000°—1150° C. out of contact with air, whereby the tungstic acid formed in the first reaction is reduced to metallic tungsten powder. The melt is quenched in water and the insoluble material washed in the usual way and graded to give a very pure product. The liquors from the extraction and washing of the product are treated with calcium chloride to recover any soluble unreduced tungsten, and the resulting calcium tungstate is added to the next charge in quantities not exceeding 10%. Means are provided for collecting the ammonia evolved in hydrochloric acid, the resulting ammonium chloride being used over again in the process.—A. R. P.

Platinum and similar metals; Process for the extraction of —— *from their sands and ores.* R. Thayer. U.S.P. 1,355,186, 12.10.20. Appl., 23.1.20.

The metals are volatilised as fume, caught in a liquid, and recovered from the liquid by electrolysis. —B. M. V.

Alloys; Method of forming ——. P. H. Brace, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,355,532, 12.10.20. Appl., 18.4.19.

Oxides of the metals to be alloyed are mixed, reduced with carbon to form carbides, and then melted *in vacuo* with the oxide of one of the metals. —B. M. V.

Silver ores; Method of treating ——. L. P. Burrows. U.S.P. 1,355,795, 12.10.20. Appl., 5.12.16. Renewed 1.11.19.

Crushed silver ore is treated at a red heat with superheated steam, then smelted, when the different metals in the ore are found in a purified condition and in separate layers in the cooled product. —A. R. P.

Melting metallic masses; Method of and furnace for ——. T. W. Muckle. U.S.P. 1,363,188, 21.12.20. Appl., 22.4.19.

A melting chamber is filled with the metal to be melted and a series of blast flames are admitted, but only after combustion has been completed outside the chamber. The hot gases permeate the metallic mass and are then exhausted through a regenerator.—B. M. V.

Manganese or alloys of manganese; Method for producing ——. M. S. Kalling and S. D. Danieli, Assrs. to Akt. Ferrolegeringar. U.S.P. 1,363,657, 28.12.20. Appl., 4.11.19.

A manganese alloy comparatively rich in silicon is exposed to free oxygen at a temperature above its melting point, *e.g.*, by blowing with air, in order to obtain an alloy low in carbon and silicon. —B. M. V.

Electroplating; Process of ——. J. S. Groff. U.S.P. 1,364,051, 28.12.20. Appl., 18.8.20.

A protective coating against corrosion is deposited on steel by making it the cathode in an electrolyte of lead fluoborate using an anode of lead and tin; the electrolysis is continued until the proportion of tin to lead in the electrolyte is substantially the same as in the anode.—D. F. T.

Suspensions [of ores etc.]; Process for the treatment of ——. A. Nathansohn. G.P. 323,836, 19.12.19.

Substances sensitive to light, *e.g*,, dyes, compounds of uranium, chromium, silver, iron, mercury, etc., or organic compounds, preferably fluorescent, such as æsculin, quinine, fluorescent dyes, or organic acids, are added to suspensions of ores or the like in suitable liquids, *e.g.*, water, hydrocarbons, etc., and the suspension then exposed to the action of light. By this treatment the electrical charge on the suspended particles is modified and they are rendered more amenable to treatment by sedimentation or electro-osmotic processes or by magnetic separation.—A. R. P.

Steel; Process of making alloy ——. A. Kissock. E.P. 131,877, 23.6.19. Conv., 28.8.18.

See U.S.P. 1,300,279 of 1919; J., 1919, 504 A. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 3477 of 1872, 1192 and 3043 of 1875, and 793 of 1879, and in pursuance of Sect. 8, Sub-sect. 2, to E.P. 131,896.)

Manganese or alloys of manganese; Production of ——. Aktiebolaget Ferrolegeringar. E.P. 135,186, 10.11.19. Conv., 12.11.18.

See U.S.P. 1,363,657 of 1920; preceding.

Waste tins; Treatment of ——. E. J. Lovegrove. U.S.P. 1,363,332, 28.12.20. Appl., 9.8.17.

XI.—ELECTRO-CHEMISTRY.

Batteries; Electric dry ——. F. Kainz. Chem.-Zeit., 1921, 45, 51—52.

The author describes the construction of dry batteries and discusses their efficiency; the latter is small and the batteries are extremely wasteful. —W. P. S.

Electric furnace for arsenic determination. Birckenbach. *See* XXIII.

Patents.

Ozone; Manufacture of ——. Soc. l'Azote Français, Assees. of F. Gros et Bouchardy. E.P. 140,777, 22.3.20. Conv., 22.3.19.

The yield of ozone by subjecting air or oxygen to the action of the silent electric discharge is increased by operating so that the gas under treatment is under a pressure of 400—150 mm. of mercury, and at a temperature below $-10°$ C. —J. S. G. T.

Ozonising apparatus. Ozoniser. W. G. Lindemann, Assr. to Ozone Co. of America. U.S.P. (A) 1,362,999 and (B) 1,363,000, 21.12.20. Appl., 15.2 and 4.8.19.

(A) A supply of ozonised water to a storage tank is automatically controlled by the water level in the tank in such manner that the ozonising apparatus operates only when large supplies of ozonised water are required. (B) An ozonising apparatus comprises an air conduit provided with inlet and discharge openings, across which a number of flat ozonising elements are arranged in a row, and spaced from the ends of the conduit. The elements engage with contact plates which are electrically connected with other contact plates mounted on longitudinal guide strips carried by a closed cylindrical metal casing. —J. S. G. T.

Electrolytic tanks with diaphragm cells. G. Haglund. E.P. 151,260, 27.8.20. Conv., 17.9.19.

An outlet whereby liquid can pass from the diaphragm cell without coming into contact with the liquid in the tank outside the cell, comprises a tube passing through the wall of the cell and making a fluid-tight connexion with a hole in the wall of the outer vessel. The tube is provided with a conical plug and is pressed against the opening in the wall of the outer vessel by a removable wedge acting on the frame of the cell.—J. S. G. T.

Electric storage battery plates; Paste for ——. T. A. Willard. E.P. 155,944, 17.10.19.

The active material for the plates, more especially the negative plates, of storage batteries using separators formed of a material other than wood, is mixed with 0·6% by weight of wood dust. —J. S. G. T.

Electrolytic cell. H. I. Allen, Assr. to Electron Chemical Co. U.S.P. 1,355,116, 12.10.20. Appl., 5.2.18.

The cover of an electrolytic cell is formed in sections, and carbon conductors projecting upwards from the anode pass through apertures at the ends of the sections.—J. S. G. T.

Gases; Apparatus for treatment of —— *by electric discharge.* E. E. Werner. U.S.P. 1,363,827, 28.12.20. Appl., 4.3.20.

An arc discharge is produced within a chamber having walls converging upwards. The orifice of an air nozzle located below the arcing ends of the electrodes diverges outwards and upwards. —J. S. G. T.

Electric batteries; Process of preparing negative plates for ——. A. Pouchain. U.S.P. 1,364,953, 11.1.21. Appl., 18.9.19.

XII.—FATS; OILS; WAXES.

Fats and oils; Determination of water in ——. H. Oertel. Chem.-Zeit., 1921, 45, 64.

In a method described previously (J., 1920, 824 A), oils containing more than 3% of water should be mixed with petroleum (oil, 4, petroleum, 16 g.) before the test is applied. Fats in any case required to be dissolved in petroleum, 18 g. of petroleum being used for 2 g. of fat.—W. P. S.

Hydrogenating metals; Preparation of active —— *in liquid media [oils].* A. Brochet. Bull. Soc. Chim., 1920, 27, 899—901.

If nickel formate is heated in cottonseed oil at temperatures below 150° C. no change occurs, but at temperatures from 160° to 270° C. the formate is decomposed and the oil undergoes partial hydrogenation. The nickel is left in an active state and will complete the hydrogenation of this and more oil in an atmosphere of hydrogen under pressure at 100° C.—W. G.

Viscosity of oils. Schwedhelm. *See* IIA.

Hydrogenating metals. Brochet. *See* X.

Patents.

Oils and fats; Apparatus for refining —— *whereby they are deodorised and their acidity is reduced.* K. H. Vakil. E.P. 154,514, 26.2.20.

In an apparatus for carrying out the process described in E.P. 155,020 (J., 1921, 90 A), the crude oil flows from a tank through a heat exchanger and an electric heater to a tower, wherein it meets an ascending current of gas (carbon dioxide or a mixture of carbon dioxide and nitrogen), which may be heated if necessary by a gas heater. The gases issuing from the tower pass through a separator wherein oil mechanically carried over is separated, and the gases are then cooled by incoming gas in a heat exchanger. The still hot gases thus deprived of easily condensable fatty acids, then meet with a jet of steam and are carried to a water-cooled condenser wherein a further condensation of impurities takes place. The gases are then purified in a scrubber by means of mineral or vegetable oil and either led to a gas holder or used for purifying a further quantity of oil as described.—A. de W.

Fat, wax, oil, gelatin, and the like; Process and apparatus for extracting ——. E. Scott and Co., Ltd., and J. Macgregor. E.P. 155,863, 17.7.19.

The material to be extracted, *e.g.*, the flesh or blubber of whales, seals, etc., is introduced into a vessel having a perforated false bottom and provided with a closed inlet at the top and a closed outlet in the side above the false bottom. Steam is admitted below the perforated bottom and/or by a jet or mechanical compressor in the upper part of the vessel until the charge is heated, after which further steam is admitted through the compressor only. The liquefied fat etc. percolates through the false bottom into a receiver provided with an outlet and a steam admission pipe, and steam is returned from the lower part of the vessel to the

compressor, in order to raise its temperature and compensate for losses due to condensation, and is then again introduced into the steam circulation. —A. de W.

Soap powders having a high percentage of liquid fats and oils; Manufacture of ——. W. J. Mellersh-Jackson. From De Nordiske Fabriker De-no-fa Aktieselskap. E.P. 155,866, 25.7.19.

Soaps manufactured in the usual way from liquid fats and oils, especially drying oils and fish oils, are concentrated to a condition in which they are easy to grind and preserve, by heating in a closed boiler to 180°—200° C. at a pressure of 15—20 atm. and distilling off 10—25% of the water whilst maintaining the pressure. The soap is thereby maintained in a liquid condition during concentration, and polymerisation of the unsaturated acids readily takes place.—A. de W.

Production of fat. G.P. 310,616. *See* XVIII.

Cooling edible fats. E.P. 155,477. *See* XIXa.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Patents.

Zinc sulphide; Manufacture of anhydrous ——, *Manufacture of anhydrous zinc sulphide adapted for use as pigment.* P. Desachy. E.P. (a) 126,625 and (b) 126,627, 5.5.19. Conv., 19.10.17.

(a) Solutions of alkali or alkaline-earth sulphides are caused to react with hydrated zinc oxide, zinc oxide, or an insoluble zinc salt of an organic or inorganic acid to produce hydrated zinc sulphide. Alternatively zinc oxide or an insoluble zinc salt is precipitated hot or cold from a solution of zinc sulphate by means of caustic soda or sodium sulphite, the supernatant liquor containing sodium sulphate being drawn off and treated with a solution of barium sulphide. The resulting sodium sulphide solution is added gradually with the aid of a jet of steam to the zinc oxide or insoluble zinc salt, which has been previously washed, in order to convert the zinc into hydrated zinc sulphide. The latter is filtered off, washed, dried at 100° C., and calcined at 450°—500° C. in the presence of sulphur in pots provided with a cover and orifice. (b) An alkali zincate is prepared by treating metallic zinc, zinc dust, zinc oxide, calcined calamine, or roasted blende reduced to a fine powder with a hot concentrated alkali solution, any lead or cadmium being precipitated when cold by addition of a saturated aqueous solution of carbon bisulphide and filtration. A current of air charged with carbon bisulphide is led into the zincate solution heated to 80°, whereby hydrated zinc sulphide is precipitated. The latter is filtered off, washed, and calcined at 450° C. in the presence of a small quantity of sulphur, with exclusion of air. —A. de W.

Phenols and aldehydes; Production of condensation products of ——. L. A. Jaloustre, Z. Kheifetz, and M. Warchavsky. E.P. 138,061, 23.9.19.

Soluble and/or fusible condensation products of phenols and aldehydes are transformed into insoluble, infusible, acid- and alkali-proof products, at ordinary atmospheric pressure and at a temperature not exceeding 120° C., by the aid of relatively large amounts of alkaline-earth bases or alkali cyanides, the latter also serving to accelerate the first phase of the condensation; *e.g.*, 100 pts. of phenol, 10 pts. of slaked lime or 5 pts. of sodium cyanide, and 160—180 pts. of 40% formaldehyde, are heated to 90°—120° C.—A. de W.

Phenols and aldehydes; Production of condensation products of ——. L. A. Jaloustre, Z. Kheifetz, and M. Warchavsky. E.P. 139,147, 23.9.19. Addn. to E.P. 138,061 (*cf. supra*).

The liquid and soluble product obtained by the interaction of equal parts of phenol and 40% formaldehyde in the presence of 5% (on the weight of the phenol) of sodium salicylate or ammonium thiocyanate is mixed with 2% (on the weight of the phenol) of sodium cyanide and heated to 95°—100° C. in an open vessel to yield a solid, insoluble, infusible, acid- and alkali-proof product.—A. de W.

Condensation products of acrolein with phenols; Process for the preparation of ——. C. Moureu and C. Dufraisse. E.P. 141,059, 31.3.20. Conv., 31.3.19.

A hard, insoluble, non-conducting resin is produced by the condensation in a single operation of phenol and acrolein with about 1% of caustic soda. The acrolein may be replaced by a resin or polymerisation product thereof.—W. F. F.

Linoleum; Working up of linoleum scraps into new ——. V. Scholz and C. Tiedemann. E.P. 143,561, 20.5.20. Conv., 16.5.18.

Linoleum scrap is heated with organic "depolymerising agents," *e.g.*, ethylene trichloride, benzoline, and/or methylated spirit to 80°—140° C., the amount of solvent used being only sufficient to effect a softening of the scrap, whereby the adhering jute fibres may be mechanically removed. The solvent is removed from the treated scrap by evaporation, and the residual pulp heated to 100°—120° C. to regenerate linoxyn and restore the qualities of toughness, glutinousness, etc., to the soft depolymerised linoxyn, whereby it may be used alone or in conjunction with fresh linoleum cement for the production of linoleum.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Influence of tapping on latex and ——. O. de Vries. Comm. Central Rubber Station, Buitenzorg, 1920, **4**, No. 22, 313—334.

Lengthening of the tapping cut or increase in the number of tapping cuts on a tapping surface, has the same effect as heavier tapping generally, the sp. gr. of the latex increasing and its rubber content diminishing, whilst the rubber vulcanises more rapidly. Tapping to the wood produced a similar result, a latex being obtained on some days containing 16% of rubber and having sp. gr. 1·0002. Tapping at different hours of the day or tapping twice daily on the same cuts caused no alteration in the properties of the rubber. On tapping a piece of bark which had been isolated by cuts to the wood, the yield of latex often failed gradually, but the rubber content of the latex never approached the neighbourhood of 10%.—D. F. T.

Rubber; Ageing of vulcanised ——. O. de Vries and H. J. Hellendoorn. Comm. Central Rubber Stat., Buitenzorg, 1920, **4**, No. 24, 429—457.

In storage experiments with vulcanised rubber at the ordinary temperature the samples underwent a continuous reduction in extensibility at a greater rate than that observed earlier by Stevens; the increase in tensile strength on storage never markedly surpassed the value obtained for the same stress-strain curve by direct vulcanisation. The maxima observed in the tensile strength were much less sharp than in Stevens' experiments, and, with a vulcanisation coefficient of 4—6, the tensile strength in several cases continued to increase for 80 weeks;

inferior samples deteriorated more rapidly. A mixture with only 5% of sulphur when fully vulcanised behaved in exactly the same way as one containing a considerable proportion of free sulphur. Whereas, however, vulcanisates with 5—10% total sulphur containing uncombined sulphur, on keeping remained dry and gradually became brittle, those containing 5% of sulphur, all of which was in the combined state as a result of prolonged vulcanisation, became weak and sticky. (*Cf.* de Vries, J., 1919, 82 A; Stevens, J., 1918, 305 T, 340 T.)—D. F. T.

Rubber; Influence of some factors in rubber preparation on the ageing qualities of the vulcanised ——. O. de Vries and H. J. Hellendoorn. Comm. Central Rubber Stat., Buitenzorg, 1920, **4**, No. 24, 458—472.

THE alteration of vulcanised rubber on storage is unaffected by "maturing" or excessive milling of the coagulum, by variation, within the usual limits, in the amount of acetic acid used for coagulation, by the use of small amounts of sulphuric acid, or by the application of sugar or salt for coagulating purposes. Coagulation by evaporation and partial coagulation yield rubbers which, like some lower grades, exhibit a more rapid deterioration with respect to tensile strength.—D. F. T.

Rubber stress-strain curve; Some aspects of the ——. W. B. Wiegand. Canadian Chem. J., 1920, **4**, 160—170. Indiarubber J., 1920, **60**, 379—383, 423—429.

AFTER reviewing the present state of knowledge of the physics of rubber from the point of view of the stress-strain relationship, hysteresis and thermal phenomena (Joule effect), experiments as to the comparative effect of various inorganic compounding ingredients on the stress-strain curve are described. Gradually increasing proportions of lampblack, gas black, China clay, red iron oxide, zinc oxide, glue, whiting, fossil flour, and barytes respectively were added to the standard mixing of rubber (100 vols.), litharge (3 vols.), and sulphur ($2\frac{1}{2}$ vols.), the mixtures being subsequently vulcanised and the "stress-strain" curve measured on a Scott machine. The toughening effect of each of the ingredients named was measured by the area included between the curve and the vertical (elongation) axis; the addition of barytes, fossil flour, glue, whiting, and red iron oxide diminishes the energy content of the stretched rubber, whereas zinc oxide, lampblack, and gas black cause an increase, the effect being greatest with the last-named. The effect of the various "fillers" runs parallel to the fineness of their particles or to the extent of the surface developed in the rubber. If the proportion of additional ingredient is raised beyond a certain limit, *e.g.*, beyond 20 vols. of zinc oxide or 40 vols. of gas black, the particles begin to agglomerate, with consequent diminution of the ultimate tensile strength and "toughening effect."—D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Skin structure and bating. A. Seymour-Jones. J. Soc. Leather Trades' Chem., 1920, **4**, 291—293.

PELT consists of grain membrane, grain or "true skin," fatty layer, and the "corium." The grain membrane is packed with hair sheaths, sebaceous glands, muscles, sweat ducts, etc., placed amidst extremely fine collagenous fibres, which are collected into bundles and held in a vertical position by elastic fibres. These maintain the structural scheme of the grain and give it elasticity. They are absent in other layers. Bating removes them, and experiments show that skins should be delimed with acid, pasted on the grain with a trypsin preparation, and then submitted to some process which will remove the fat from the fatty layer. A completely satisfactory process has not yet been evolved. —D. W.

Fat-liquoring [chrome leather]; Effect of soap in ——. R. F. Innes. J. Soc. Leather Trades' Chem., 1920, **4**, 299—300.

EXPERIMENTS on fat-liquoring chrome-tanned goat skin with different quantities of soap showed that an acid chromium soap was formed by the double decomposition of the soap with the basic chromium sulphate in the leather, giving potassium sulphate, which remained in the solution. Two batches of leather were fat-liquored under the same conditions with a potassium soap and a sodium soap of the same strength and quantity of total fatty acids. No difference could be detected in the finished leathers, and no potassium was found in the batch treated with potassium soap. The soap in a fat-liquored skin cannot be extracted by water, since a water-soluble soap is no longer present. The alkali in the soap merely acts as a carrier of the fatty acids. The basicity of the chromium salt on the fibres of the leather diminishes with increased amount of soap in the fat-liquor.—D. W.

Gelatin and glue; Jelly value of ——. M. Ishikawa. Kôgyô Kwagaku Zasshi (J. Chem. Ind. Tokyo), 1920, **23**, 1147—1152.

THE following modification of Clark's method (J., 1918, 665 A) is proposed:—A test-tube of 1·2 cm. inner diameter, having a mark 1 in. from the bottom, is filled with the sample (2% gelatin solution or 5% glue solution) to the mark and immersed in a beaker filled with water and provided with a thermometer. The beaker is cooled with ice water during more than 1 hr., then warmed gradually to the m.p. of the sample, *i.e.*, until the surface of the sample just forms a horizontal plane on inclining the tube.—K. K.

XVI.—SOILS; FERTILISERS.

Potash lime, magnesia; Respective rôle of the three bases—— in cultivated plants. H. Lagatu. Comptes rend., 1921, 172, 129—131.

FROM the analyses of numerous plants the author has calculated the basic equivalents, $K_2O/2$, $CaO/2$, $MgO/2$, in 100 basic equivalents attributable to these three bases and plotted the results on a triangular diagram for a large number of different species. The ratio MgO/CaO is only >1 in the case of sugar beet, maize, potatoes, and mangels, exactly 1 for wheat, and just under 1 for oats, rye, barley, and buckwheat.—W. G.

Phosphates in basic slag; Effect of fluorspar additions on the ——. F. Bainbridge. Iron and Steel Inst., Carnegie Scholarship Mem., 1920, 1—40.

Parts I. and II. Manurial value of basic slag containing fluorspar. Continuing the work previously described (J., 1919, 649 A), experiments were made to examine the possibility of increasing the fertilising value of insoluble phosphate by adding it to the soil in the late autumn and thus exposing it during the winter to the action of the atmosphere. The results showed a bigger proportionate yield compared with a soluble slag when the insoluble phosphate was applied in the autumn instead of in spring. The insoluble slag gave satisfactory yields of both grain and straw (barley), but failed to give the increased phosphate content of grain and straw given by soluble slag.

Part III. Nature and solubility of the phosphates contained in basic open-hearth slag made with additions of fluorspar. In experiments to prepare synthetically the compounds presumed to be present in basic slag, uncombined lime in the fusions was determined by passing steam over a weighed quantity of the material contained in a platinum boat in a silica tube heated to 140° C., the gain in weight being attributed to the hydration of lime. Tribasic calcium phosphate is much more soluble in 2% citric acid than in ammonium citrate solution; consequently the use of the latter solvent was abandoned. The fusion of the tribasic phosphate with calcium fluoride caused a rapid fall in the solubility of the phosphate up to a point corresponding with 8pts. CaF_2 to 100 pts. of phosphate. Tetrabasic calcium phosphate was prepared by fusing the tribasic phosphate with lime in the oxy-acetylene blowpipe flame. The product contained 94·12% of tetrabasic phosphate and 0·9% of free lime. A solubility determination showed that only 21·5% of the phosphate present was soluble when ground to 100-mesh, but 72·26% when ground to flour. The tetrabasic phosphate is decomposed when fused with calcium fluoride, apatite being formed, with the result that the solubility is lowered. Silico-carnotite, $3CaO,P_2O_5;2CaO,SiO_2$, was prepared by fusing dicalcium silicate with tribasic calcium phosphate, and was completely soluble in citric acid. Fusion of silico-carnotite with calcium fluoride rapidly lowered the solubility. A number of fusions of basic slag with varying quantities of calcium fluoride were made, and the products were analysed and their solubilities determined. Curves are given showing the lowering effect on the solubility of the phosphate of increasing quantities of calcium fluoride. It is concluded that the addition of calcium fluoride to basic open-hearth slags results in the formation of an apatite of the formula $3(3CaO,P_2O_5),CaF_2$. Crystals which were identified as apatite were actually obtained from such a slag. In extremely soluble basic slags the phosphate is probably present as silico-carnotite or steatite. Free lime does not exist to any extent in normally prepared slag containing about 14% P_2O_5.

Appendix. Effect of the addition of lime on the citric acid solubility of a basic slag. The result of re-fusing a slag, without addition of lime, is to increase considerably the solubility of the phosphate present. Addition of lime does not affect appreciably the solubility of the phosphate, whilst the added lime combines, probably with the iron oxide present, to form a compound almost insoluble in citric acid.—E. H. R.

Potash in commercial wood ashes; Availability of ——. R. E. Rose. J. Assoc. Off. Agric. Chem., 1920, 3, 323—326.

THE potassium in wood ashes is present chiefly in the form of carbonate and very little, if any, exists as silicate, and there is nothing to be gained by extracting the material with 1% citric acid solution in place of boiling water in determining the available potash.—W. P. S.

Kjeldahl-Gunning-Arnold method for the determination of ammonia in fertilisers; Substitution of sodium sulphate for potassium sulphate in the ——. T. D. Jarrell. J. Assoc. Off. Agric. Chem., 1920, 3, 304—306.

PRACTICALLY identical results were obtained, whether sodium sulphate or potassium sulphate was used.—W. P. S.

Sulphur; Mechanism of the fertilising action of ——. G. Nicolas. Comptes rend., 1921, 172, 85—87.

IN addition to the other rôles played by sulphur, it is shown that it favourably influences the assimilation of carbon dioxide by plants. The optimum dressing of sulphur varies with the species of plant. —W. G.

PATENT.

Nitrogenous phosphatic material and process of producing the same. F. S. Washburn, Assr. to American Cyanamid Co. U.S.P. 1,355,369, 12.10.20. Appl., 23.7.20.

CRUDE calcium cyanamide is treated with water, and the resulting solution is treated with phosphoric acid.—W. J. W.

XVII.—SUGARS; STARCHES; GUMS.

Sugar solutions; Refraction and dispersion of ——. H. Krüss. Z. Ver. deuts. Zuckerind., 1920, 617—625.

FROM the values determined by Matthiesson (Diss., 1898), Main (Int. Sugar J., 1907, 9, 481), and Schönrock (Z. Instrk., 1911, 31, 191), the author has compiled a single table of refractive indices of sugar solutions at 20° C. (based on a smoothed-out curve), which is considered to be more accurate than the individual tables from which it was compiled. On the basis of this table Matthiesson's values for the refractive indices of sugar solutions for the C, D, and F lines have been corrected. The optical design of Schönrock's sugar refractometer (J., 1914, 154) is discussed.—J. H. L.

Sugars and polyatomic alcohols; Reactions of —— in boric acid and borate solutions, with some analytical applications. G. Van B. Gilmour. Analyst, 1921, **46**, 3—10.

THE combination of polyatomic alcohols, sugars, and many hydroxy compounds with boric acid to produce stronger acids is discussed. When an excess of mannitol is added to boric acid, mannitoboric acid is formed; this yields a sodium salt which is stable in acid solution, but decomposes in neutral or alkaline solution with the production of sodium metaborate and mannitol. The metaborate then combines with mannitol to form compounds like $NaBO_2,3C_6H_{14}O_6$. This type of reaction may be considered general for the polyhydroxy compounds that permit of the volumetric determination of boric acid. Amongst the analytical applications of the reactions is the determination of lævulose in invert sugar etc. A weighed amount of the latter is treated with 10 c.c. of $M/10$ boric acid solution and 0·5 c.c. of 1% phenolphthalein solution, and the mixture is titrated with $N/10$ sodium hydroxide solution. The quantities of lævulose corresponding with the various volumes of alkali solution are as follows:—7·2 c.c., 0·22 g.; 8·1 c.c., 0·27 g.; 8·5 c.c., 0·31 g.; 8·9 c.c., 0·36 g.; 9·2 c.c., 0·40 g.; 9·5 c.c., 0·45 g.—W. P. S.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes; Formation of ——. E. Köhler. Biochem. Zeits., 1920, **112**, 236—254.

THE course of fermentation depends on the formation of a pro-enzyme of zymase and on the activation of the latter. Maltose is capable of activating zymase, whilst other sugars, such as dextrose, sucrose, and lævulose, have an inhibiting action. On the other hand, in the production of the pro-enzyme maltose exerts an inhibiting influence in contradistinction to the other sugars. This explains the different physiological behaviour of certain yeasts to the various sugars.—S. S. Z.

Enzyme action; Mechanism of ——. I. Rôle of the reaction of the medium in fixing the optimum temperature of a ferment. A. Compton. Proc. Roy. Soc., 1921, B, **92**, 1—6.

EXPERIMENTS with a highly active maltase preparation indicate that the optimum temperature of a ferment or ferment function, occurring in a given enzyme preparation, is independent of the concentration of the enzyme, the duration of the action and the hydrogen ion concentration of the medium being constant (*cf.* Compton, J., 1914, 977).
—J. C. D.

Peroxydases. II. R. Willstätter and M. Bommer. Annalen, 1921, **422**, 47—73.

SLICED horse-radish which is immersed in flowing water so that dialysis takes place through the cell walls generates new peroxydase so long as the cells retain their vitality. The peroxydase number falls during the first four days and then increases during the following two or three weeks. If the dialysing water contains toluene new peroxydase is not formed and the peroxydase number falls rapidly owing to exosmosis of the enzyme. Evidence is recorded to show that the plant material contains two peroxydases, one of which is easily soluble, the other completely insoluble, in water. During dialysis the amount of the soluble peroxydase decreases, and that of the insoluble peroxydase increases with the time, so that in the preparation of peroxydase extract the time of dialysis should not exceed 12 days. Peroxydase is almost completely adsorbed by aluminium hydroxide from a solution in 50% alcohol at a concentration of 0·05%, and 90—95% of the peroxydase is recovered in solution in a more active condition by agitating the adsorption product with water containing carbon dioxide at 0°—20° C. On this discovery is based a modification of Willstätter and Stoll's method of preparing peroxydase extract (Annalen, 1918, **416**, 21) whereby an active peroxydase preparation (purpurogallin number 860) is obtained from horse-radish with a great saving of time and labour. (*Cf.* J.C.S., Feb.)—C. S.

Lactic acid; Separation and identification of ——, as complex ferric-sodium lactate. K. A. Hofmann. Ber., 1920, **53**, 2224—2226.

To separate lactic acid from fermentation products the solution is mixed with little more than the estimated amount of ferric chloride, rendered alkaline with sodium carbonate, acidified with acetic acid, and evaporated on a water bath, when a characteristic very pale green precipitate of ferric-sodium lactate, $[Fe(C_3H_4O_3)_2]Na,2H_2O$, separates in the course of a few hours. This is almost insoluble in water at 20° C., and is only slowly attacked by dilute alkalis, 1% hydrochloric acid, 15% acetic acid, or tannic acid. (*Cf.* J.C.S., Feb.)—J. C. W.

Glycerol in cider vinegar, Isolation and identification of ——. R. W. Balcom and E. G. Grab. J. Assoc. Off. Agric. Chem., 1920, **3**, 411—412.

GLYCEROL was extracted from 5 l. of cider vinegar by the official (American) method for the determination of glycerol in vinegar; the glycerol was then distilled under reduced pressure in the presence of sandalwood oil, the aqueous solution obtained, after removal of the sandalwood oil, was evaporated at a low temperature, and the glycerol dried under reduced pressure over sulphuric acid. The product thus obtained was proved to be pure glycerol by oxidation with bichromate (usual method for the determination of glycerol) and by the m.p. of its benzoyl derivative.—W. P. S.

Papain. Chesnut. *See* XX.

PATENT.

Fat from raw materials containing carbohydrates; Production of —— by means of fungi. Kriegsausschuss f. pflanzliche u. tierische Oele u. Fette G.m.b.H. G.P. 310,616, 6.6.16.

MATERIALS such as turnips, potatoes, apples, or pears in subdivided form are inoculated with fungi of the sachsia, oidium, endomyces, or yeast groups, and allowed to ferment with access of air. Either before or during fermentation an ammonium salt, urea, or sugar, may be added. When distillery yeast or "mineral yeast" is employed an oil of good quality, similar to olive oil, and containing glycerides of fatty acids with traces of free acid, is produced.—W. J. W.

XIXA.—FOODS.

Milk; Indirect analysis of —— and the detection of added water. A. Bouriez. Ann. Falsif., 1920, **13**, 606—618.

THE total solids, casein, soluble matters other than casein, sp. gr. of the serum, and sp. gr. of the fat-free milk may be calculated from the fat content and the sp. gr. of the milk. Total solids (g. per litre) $=1{\cdot}17B+8/3\times1000(D-1)$; casein $=0{\cdot}3(T-B)$; soluble matters $=0{\cdot}7(T-B)$; sp. gr. of the serum $=750(T-B)/2{\cdot}5(1000D-T)+(T-B)$; and sp. gr. of the fat-free milk $=375(T-B)/(1000D-T)+0{\cdot}625(T-B)$, where T = total solids, B = g. of fat per litre, and D = the sp. gr. at 15° C.—W. P. S.

Milk serum [; Specific gravity of ——]. R. Ledent. Ann. Falsif., 1920, **13**, 601—605.

THE sp. gr. of milk serum (obtained by heating the milk at 70° C. with the addition of 20% acetic acid)

varies from 1·027 to 1·029, and is decreased to 1·026 by the addition of 10% of water to the milk. Milk from diseased cows yields a serum having a sp. gr. lower than the limit mentioned. A low sp. gr. indicates therefore the presence of added water or that the milk is from a diseased cow.—W. P. S.

Lard; Detection of beef fat in ——. Vitoux and C. F. Muttelet. Ann. Falsif., 1920, **13**, 593—601.

The method described is that proposed originally by Bömer (J., 1913, 434), and depends on the presence of α-palmitodistearin, m.p. 68·5° C., in lard, and of β-palmitodistearin, m.p. 63·3° C., in beef fat. The fatty acids separated from these two glycerides melt at 63·2° C. 50 g. of the fat is dissolved in 50 c.c. of pure acetone, the solution is cooled to 15° C., and after 1 hr. the separated crystals are collected on a filter, dried over sulphuric acid, then dissolved in 50 c.c. of ether and again allowed to crystallise. These crystals are collected, the m.p. determined, a portion then saponified, the fatty acids separated, and their m.p. determined. The crystals of glycerides obtained from pure lard melt above 62° C., those from beef fat at about 58·5° C. In the case of pure lard the value $(2G-A)$ is never less than 68°; $G=$ the m. pt. of the crystals, and $A=$that of the fatty acids.—W. P. S.

Antiscorbutic action of raw potatoes, crushed and whole. Bezssonoff. Comptes rend., 1921, **172**, 92—94.

The antiscorbutic action of raw peeled potatoes, not crushed, is equal to that of vegetables having a marked antiscorbutic action, such as the cabbage or dandelion, but if the potatoes are first crushed the action is much inferior. The expressed juice possesses an antiscorbutic action, but less than that of the equivalent weight of uncrushed potato, whilst the action of the marc is practically nil.—W. G.

Proteins; Free amino groups of ——. *II.* S. Edlbacher. Z. physiol. Chem., 1919, **108**, 287—294. (*Cf.* J., 1920., 796 a).

The "formol value" and the "methyl value" obtained by methylating with dimethyl sulphate were determined in gelatin and casein digested with pepsin and in gliadin and zein digested with hydrochloric acid and in some undigested proteins. The relation of the figures obtained to the free amino groups in the protein molecule is discussed. In esocin, scombrin, gliadin, and zein there appears to be a certain parallelism between the lysine content and the free amino groups. Clupein and salmin, which are free from lysine, contain a larger number of nitrogen atoms in the form of groups, probably imino groups, which can be methylated but are not indicated by formol titration. In gelatin, casein, sturin, edestin, and cyprinin, the "methyl values" indicate 3—5 CH_3 groups attached to nitrogen for each amino group shown by formol titration, so that each free amino group is probably converted into a $N(CH_3)_3$ on methylation. Thymus- and gadus-histones, on the other hand, show a much higher content of nitrogen by formol titration than corresponds to the "methyl value."—S. S. Z.

Histidine; Separation of —— *from arginine.* A. Kossel and S. Edlbacher. Z. physiol. Chem., 1920, **110**, 241—245.

In the method described previously (Z. physiol. Chem., 1901, **31**, 171) for the separation of histidine and arginine by precipitation at different degrees of alkalinity of the medium, precipitation of histidine is complete even in absence of the more strongly alkaline arginine. The precipitation of histidine begins whilst the reaction of the medium is still acid and is complete when the solution reddens phenolphthalein. Iminazole behaves similarly, as also do carnosine and guanidine, except that in the last two cases there is no precipitation so long as the medium is still acid or even neutral to litmus. Methylguanidine is precipitated incompletely in a medium which reddens phenolphthalein and completely when the solution gives a blue colour with thymolphthalein. Arginine is precipitated only when the solution gives a blue colour with thymolphthalein; creatinine is precipitated incompletely under the same conditions. Glycine gives a white precipitate in a medium which reddens phenolphthalein and a brown precipitate in a medium which gives a blue colour with thymolphthalein.

Sericin and the quantitative estimation of its constituents. W. Türk. Z. physiol. Chem., 1920, **111**, 71—75.

Silk was treated with water at 145° C. for 3 hrs. under a pressure of 3 atm. Sericin went into solution and was partly precipitated from it with absolute alcohol. Both the soluble and insoluble portions were examined for the various protein colour reactions. Those depending upon the presence of a carbohydrate complex in the protein molecule, *e.g.*, the reactions with α-naphthol and with thymol, were very intense, and were the same for both the soluble and insoluble portions. A mixture of 300 g. of the alcohol-insoluble sericin and 100 g. of the alcohol-soluble portion was hydrolysed with sulphuric acid and yielded (calculated to dry substance) 5·69% of tyrosine, 1·79% of leucine, 6·81% of serine, 4·56% of arginine, 1·96% of lysine, and 1·02% of histidine.—S. S. Z.

Patents.

Fats; Cooling apparatus for use in the manufacture of edible ——. W. Clayton and G. Nodder. E.P. 155,477, 6.11.19.

A series of hollow disc-shaped sections are placed face to face to form the body of the cooler; a cooling liquid is passed through the interior of the sections and the fat to be cooled is forced through the narrow circular chambers between the discs. These chambers are provided with scrapers fitted to a rotating shaft passing through the centres of the discs.—W. P. S.

Vegetables and the like; Apparatus for drying ——. W. Spoelstra. E.P. 155,625, 2.9.19.

The material is fed on to the uppermost of a series of shelves arranged between the two walls of a rotating vertical double-walled cylindrical vessel. The shelves are divided into sectors and as the apparatus rotates each sector is tilted in turn and discharges its contents on to the shelf beneath. Hot air passes up the central chamber and through adjustable openings into the space between each pair of shelves thus supplying fresh drying air to the material on each shelf.—L. A. C.

Drying liquids [*e.g. milk*]. J. H. Akkerman. E.P. 155,927, 9.10.19.

The liquid to be dried is applied by a spraying or like device to a rapidly rotating disc which is not heated but may be in a moisture-absorbing atmosphere; the conditions are adjusted so that the material is dry before it leaves the disc, and if it should stick there is no need to remove the dry material continually as no heat is applied to it.
—B. M. V.

Milk; Process for making evaporated ——. O. W. Mojonnier. U.S.P. 1,362,728, 21.12.20. Appl., 8.5.20.

The milk is condensed by heat and a number of

samples are withdrawn and, after addition of varying quantities of sodium bicarbonate, are heated at 243° F. (117° C.) for 15 mins. in a steam retort with a cage revolving at a rate of 10 revs. per min. The samples are cooled with cold water, and the quantity of sodium bicarbonate required by the bulk of the milk for sterilisation is ascertained by selecting the best sample.—L. A. C.

Fruit-juice; Process of treating ——. Process of making jelly. Process of making fruit syrup. M. O. Johnson. U.S.P. (A) 1,362,868, (B) 1,362,869, and (C) 1,362,870, 21.12.20. Appl., (A and B) 12.9.19, (C) 17.1.20.

Fruit-juice is concentrated by freezing a portion of the water content and separating the residual liquid, and is then clarified by heating to a temperature high enough to coagulate suspended matter but not high enough to impair the flavour. After separation of coagulated matter the juice is (A) sterilised by heating to a temperature below that employed for coagulation, and (B) jellified after addition of sugar. In (C) sugar is added to the juice before coagulation to obtain better clarification.—L. A. C.

Desiccating liquids. U.S.P. 1,362,590. *See* I.

Moisture in cereals. E.P. 143,191 and 155,486. *See* XXIII.

XIXb.—WATER PURIFICATION; SANITATION.

Arsenical insecticides; Determination of arsenious acid and arsenic acid in the presence of each other in ——. R. C. Roark. J. Assoc. Off. Agric. Chem., 1920, 3, 358—368.

To determine arsenious acid in lead arsenate a weighed portion of the sample is boiled for 30 mins. with 100 c.c. of dilute sulphuric acid, cooled, diluted to 200 c.c., and filtered; 100 c.c. of the filtrate is nearly neutralised with sodium hydroxide, excess of sodium bicarbonate is added, and the arsenious acid is titrated with $N/20$ iodine solution. Of 100 samples examined by the author, 15 contained 0·34—3·54% As_2O_3. Arsenic acid (together with antimony) is determined by a method depending on the reaction $As_2O_5+4HI=As_2O_3+2I_2+2H_2O$. A portion of the sample is treated with concentrated hydrochloric acid, the mixture evaporated to dryness, the residue dissolved in 50 c.c. of concentrated hydrochloric acid, 10 c.c. of 20% potassium iodide and 50 c.c. of 25% ammonium chloride solution are added, and the liberated iodine is titrated with thiosulphate solution, which has been standardised against pure lead arsenate. The method of determining arsenic acid in lead arsenate may be applied to zinc arsenite, and the total arsenic in this compound may be determined by dissolving the sample in acetic acid, precipitating the zinc as oxalate, and titrating the arsenic in the filtrate after reduction with potassium iodide and sulphuric acid.
—W. P. S.

Chinosol. W. Spoon. Comm. Central Rubber Stat., Buitenzorg, 1920, 4, No. 22, 335—345.

Chinosol is sometimes added as a disinfectant to latex to prevent "spottedness" and "rustiness" in the finished rubber. As the active principle, o-hydroxyquinoline, is present as sulphate, frequently admixed with potassium sulphate, the value of commercial chinosol is conveniently determined from its content of o-hydroxyquinoline calculated from the expression $9{\cdot}05\times(S-0{\cdot}41K)$ in which S and K represent respectively the percentage of sulphur and potassium.—D. F. T.

Chloromethyl carbonates and chlorocarbonates; Toxicity of the ——. A. Mayer, H. Magne, and L. Plantefol. Comptes rend., 1921 172, 136—139.

The toxic effect of the chloromethyl carbonates, as measured with rabbits, guinea-pigs, and dogs, increases with the successive introduction of chlorine atoms up to the trichloro stage. The introduction of a fourth chlorine atom if the first three were all in one methyl group diminishes the toxicity, but does not alter it if they were distributed between the two groups. The introduction of two further atoms of chlorine notably increases the toxicity. The most symmetrical distribution of the chlorine atoms gives the least toxicity. The chloromethyl chlorocarbonates become more and more toxic as the number of chlorine atoms increases, and for the same number of chlorine atoms present in the molecule they are more toxic than the carbonates.—W. G.

Hydrogen cyanide. Sieverts and Hermsdorf. *See* VII.

Patents.

Water-softening apparatus. J. E. Caps. U.S.P. 1,362,673, 21.12.20. Appl., 29.3.17.

In a water-softening apparatus, comprising a container for the water to be treated, a filter-bed containing water-softening agent, and a reservoir for the regenerating liquid, the variations of the water level control a mechanism which operates valves whereby the regeneration and flushing of the filter-bed, and the re-filling of the water-container, are effected consecutively.—W. J. W.

Copper-containing compound for treating plant diseases and process of making it. G. Morselli. U.S.P. 1,362,172, 14.12.20. Appl., 5.5.19.

Cupric chloride solution (46° B., sp. gr. 1·4646) is treated with a slight excess of milk-of-lime containing 15% of calcium hydroxide; the precipitate formed is collected, washed, dried, and powdered. It has the composition $CaCl_2,3CuO,xH_2O$.—W. P. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Thebaine; Reduction products of ——. M. Freund and E. Speyer. Ber., 1920, 53, 2250—2264.

A phenolic dihydrothebaine has already been obtained by reducing thebaine with sodium and alcohol. Hydrogenation in cold $N/1$ hydrochloric acid in the presence of spongy platinum yields a new dihydrothebaine which is insoluble in sodium hydroxide, whereas a reduction product of this, namely dihydrothebainone, is formed if colloidal palladium is the catalyst. On hydrolysis with dilute mineral acids the new dihydrothebaine loses methyl alcohol and gives dihydrocodeinone. (*Cf.* J.C.S., Feb.)—J. C. W.

r-Ecgonine and tropinone; Complete synthesis of ——. R. Willstätter and M. Bommer. Annalen, 1921, 422, 15—35.

Potassium ethyl acetonedicarboxylate, obtained

from citric acid, is electrolysed in a divided cell, whereby ethyl succinyldiacetate $C_2H_4(CO.CH_2.CO_2C_2H_5)_2$, prisms, m.p. 46°—47° C., is obtained, which reacts with a warm, concentrated solution of methylamine acetate to give ethyl 1-methylpyrrole-2.5-diacetate, domed prisms, m.p. 163°—164° C. This is reduced in acetic acid suspension by hydrogen and platinum black (containing oxygen) to ethyl 1-methylpyrrolidine-2.5-diacetate, b.p. 162·5° C. at 9 mm., which after dilution with cymene, is converted by sodium powder at 172° C. into ethyl tropinonecarboxylate, from which tropinone is obtained by boiling with 10% sulphuric acid and r-ψ-ecgonine ethyl ester by reduction with sodium amalgam; the latter, after conversion into the methyl ester and benzoylation, yields r-cocaine. (*Cf.* J.C.S., Feb.)—C. S.

Papain. V. K. Chesnut. J. Assoc. Off. Agric. Chem., 1920, **3**, 387—397.

THE paper deals with the examination of dried papaya latex obtained from papaya trees (*Carica papaya*); the material is easily powdered between the fingers and possesses little or no offensive odour. It is sometimes largely adulterated with starchy substances. A method for determining the activity of the latex depends on its proteolytic action on casein at 37·5° C. in solutions having hydrogen ion concentration of $p_H=9{\cdot}35$, the action being stopped after 30 mins. by the addition of 30 c.c. of Bogdandy mixture (magnesium sulphate, 50 g., 95% alcohol, 100 c.c., water to 1 l.) and 5 c.c. of $N/1$ hydrochloric acid, the mixture then diluted to a definite volume, filtered, and the filtrate polarised in a 200-mm. tube.—W. P. S.

Proteins; Precipitation of —— by tannins. T. Sollmann. J. Pharm. Exp. Ther., 1920, **16**, 49—59.

THE precipitation of proteins by tannin depends on the reaction of the medium. In solutions of the concentration (0·1—0·5%) necessary to produce astringent action precipitation is greatest at $p_H=2$—5. There is no precipitation when the alkalinity is $p_H>8$—8·3. The precipitation limits are the same for Witte's peptone as for egg albumin and serum-albumin, and for extracts of catechu as for ordinary tannin. Gallic acid produces, within the same limits, only slight precipitation, probably due to contamination with tannin.—J. C. D.

Mercury compound; A lipotropic ——. [Determination of mercury.] H. Hüsgen. Biochem. Zeits., 1920, **112**, 1—21.

A "LIPOTROPIC" mercury compound, MAT (4-*p*-tolueneazoacetanilide-3-mercurihydroxide, $CH_3.C_6H_4.N_2.C_6H_3(NH.C_2H_3O).Hg.OH$), is described, which when injected into rabbits is taken up by the central nervous system, the muscles, and other organs much more readily than when ordinary mercury preparations are used. The method used for estimating mercury in the brain consists of the incineration of the organic matter and electrolysing the mercury, which is afterwards volatilised into a capillary tube which is weighted.—S. S. Z.

Saccharin and dulcin; Sweetness of ——. T. Paul Chem.-Zeit., 1921, **45**, 38.

THE addition of dulcin to saccharin considerably increases the sweetening power of the latter, although dulcin possesses but little sweetness, *e.g.*, a mixture of saccharin, 280, and dulcin, 120 mg., dissolved in 1 l. of water has the same degree of sweetness as a solution containing 535 mg. of saccharin per l. The taste of the mixture is more pleasant than that of saccharin alone.—W. P. S.

Hydrazines; Preparation of some ——. L. Thompson. J. Soc. Dyers and Col., 1921, **37**, 7—11.

SODIUM hydrosulphite can be used with advantage in place of bisulphites and stannous salts in the preparation of hydrazine derivatives. Phenylhydrazine, for example, is obtained in more than 90% yield by treating a solution of phenyldiazonium chloride (1 mol.) with a concentrated solution of sodium hydrosulphite (1 mol.) at 0° C. in presence of an excess of hydrochloric acid. Complete reduction occurs immediately, and the hydrazinesulphonate is hydrolysed to phenylhydrazine hydrochloride by boiling the solution for a few minutes with a further quantity of concentrated hydrochloric acid. The reactions are expressed by the equations: — $C_6H_5N_2Cl+Na_2S_2O_4+H_2O=C_6H_5NH.NHSO_3Na+NaCl+SO_2$, and $C_6H_5NH.NHSO_3Na+HCl+H_2O=C_6H_5NH.NH_2,HCl+NaHSO_4$. Phenylhydrazine-*p*-sulphonic acid is similarly obtained in 60% yield by reduction of diazotised sulphanilic acid with the theoretical quantity of hydrosulphite solution. The reduction of *p*-nitrophenyldiazonium chloride by means of hydrosulphite is best carried out in alkaline solution. The product is a mixture of the sodium salt of *p*-nitrophenylhydrazine and a small quantity of the hydrazinedisulphonate. After hydrolysing the latter by boiling with concentrated hydrochloric acid the base is isolated in the usual way, the yield amounting to 95% of the thoretical. —G. F. M.

Formaldehyde; Preparation of —— from ethylene. R. Willstätter and M. Bommer. Annalen, 1921, **422**, 36—46.

BY passing a mixture of ethylene (19·38%), oxygen 7·58%), and nitrogen (73·04%) at the rate of 1·5 l. in 13—21 mins. through a Jena glass tube (45 cm. by 3 mm.) heated at 585° C., the authors have obtained formaldehyde in 109% (by weight) yield, calculated on the ethylene consumed; that is, about half the quantity theoretically obtainable. The concentration of the formaldehyde in the hot gaseous mixture should not exceed 2% (by vol.).—C. S.

PATENTS.

Alkaloid of ergot; Process for the isolation of the principal —— in the pure crystallised state. Chem. Fabr. vorm. Sandoz. E.P. 140,056, 20.12.19. Conv., 10.3.19. Addn. to E.P. 125,396 (J., 1920, 349 A).

THE crude alkaloid obtained by the process described earlier is purified by crystallisation from acetone preferably containing 5—10% of water. —D. F. T.

Theobromine; Preparation of dialkyl-amino-ethyl derivatives of ——. Soc. Chim. des Usines du Rhône, anc. Gilliard, P. Monnet et Cartier. E.P. 155,748, 27.5.20. Conv., 1.3.20.

DIALKYL-AMINO-ETHYL derivatives of theobromine are obtained by the action of chloroethyl-diethylamines on metallic salts of theobromine. Thus diethylamino-ethyl-theobromine, m.p. 67° C., is obtained by boiling for several hours 20 pts. of sodium-theobromine suspended in benzene with 15 pts. of chloroethyl-diethylamine. The base gives a neutral, water-soluble hydrochloride, which after crystallisation from alcohol forms colourless crystals, m.p. 202° C. This neutral salt possesses the advantages over other soluble derivatives of theobromine that, whilst having all the therapeutic properties of this substance, it does not excite the mucous membrane and has no irritating effect when used for injection.—G. F. M.

Acetaldehyde; Process of making ——. H. L. Bender. U.S.P. 1,355,299, 12.10.20. Appl., 20.6.19.

A MIXTURE of steam and acetylene is heated below 400° C. in the presence of a catalyst.—L. A. C.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic emulsions; Analysis of ——. A. B. Hitchins. Bull. Soc. Franç. Phot., 1920, 7, 228—234.

FOR the determination of gelatin in photographic emulsion films a Kjeldahl nitrogen estimation is made, and the factor 0·0082 is taken as representing the relation between the number of c.c. of $N/10$ acid equivalent to the ammonia produced and the weight in grms. of dry gelatin in the sample; air-dried gelatin (as in emulsion films) is taken as containing 13% of moisture. The total silver halide is determined by direct weighing on an asbestos filter, the gelatin being first decomposed and removed with dilute nitric acid. Total silver is determined by Volhard's method, after reducing the halides with zinc and sulphuric acid. Where the halides are only bromide and iodide or bromide and chloride the proportions are obtained from these two figures, graphs being used to simplify the calculation. Where all three halides are present they are detected by converting them into sodium salts and then testing for and removing iodide by persulphate and acetic acid, then testing for and removing bromide by persulphate and sulphuric acid, leaving the chloride still in solution. The iodide can also be quantitatively separated and determined by this method, followed by titration with thiosulphate, the proportion of chloride and bromide in the remainder being determined as outlined above. —B. V. S.

[Photographic] reversed dye images; Method of producing ——. J. I. Crabtree. Communication No. 67 from Eastman Kodak Res. Lab. Brit. J. Phot., 1921, 68, 32—33.

IF a gelatin film containing a silver image be stained with Methylene Blue and then treated with "acid-hypo" (sodium thiosulphate solution containing free sulphurous acid), the dye in the neighbourhood of the silver image is reduced, but not that in the clear gelatin; by washing the film to remove the leuco-compound thus formed and then dissolving the silver in thiosulphate-ferricyanide solution or similar agent a reversed dye image is formed. The silver image becomes much lighter in colour and more transparent, and not completely soluble in the weaker silver solvents such as potassium cyanide. Acid solution of cerous nitrate, acid amidol, and acid stannous chloride act similarly to the "acid-hypo"; a number of other dyes which are easily reduced to leuco-bases behave similarly to Methylene Blue. In practical application of the process it is necessary to select a dye which is removed from gelatin by washing much less easily than its leuco-compound.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Method of determining the water-content of wet ——. A. Logothetis and G. Gregoropoulos. Z. ges. Schiess- u. Sprengstoffw., 1921, 16, 1—2.

A KNOWN volume of 96% alcohol is stirred with the wet nitrocellulose for 5—10 mins., after which it is filtered, with continued stirring. The volume of the alcoholic filtrate is then carefully measured, and its strength calculated from a specific gravity determination, a correction being applied for contraction in volume.—W. J. W.

Mercury fulminate; Behaviour of —— *with various solvents.* A. Langhans. Z. ges. Schiess- u. Sprengstoffw., 1920, 15, 219—221, 227—229, 235—237.

BOTH white and grey fulminate give the pure, white fulminate when their solutions in potassium cyanide are precipitated with nitric acid. The cyanide solutions are not stable. No double salts can be detected in the cyanide solution, nor are these produced by interaction with ammonium nitrate or ammonium sulphate. With ammonium thiocyanate, however, a double salt is formed. A solution of fulminate in 22% ammonia solution (sp. gr. 0·92) yields columnar white crystals of fulminate, which become opaque on treatment with water. The solution decomposes in 12 hrs., and variously coloured sediments are deposited in which no trace of mercuric fulminate is found; these consist of reduction products. A double salt is produced by interaction of the ammonia solution with ammonium thiocyanate. In mono-, di-, and trimethylamine, fulminate dissolves with some difficulty, and with separation of metallic mercury. From the monomethylamine solution white, needle crystals, in fern-shaped masses, are formed; separate needles crystallise out from the di- and trimethylamine solutions. The solutions are not stable. In sodium thiosulphate solution and in aniline solution of the fulminate is accompanied by decomposition. Pyridine dissolves mercury fulminate, and cubical crystals may be obtained, which can be converted into pure fulminate by treatment with water. The pyridine solution is fairly stable, and fulminate precipitated from it after 20 hrs. is of a fair degree of purity, although yellowish in colour. Some separation of mercury, which takes place during solution, is due to interaction of the solvent with organic impurities and not to decomposition of the fulminate. Pyridine as a denaturant for alcohol in the manufacture of fulminate causes low yields, but increases the explosibility of the product. Sodium xanthate dissolves fulminate slightly; the filtrate yields crystals of addition products. On standing decomposition takes place. Mercury fulminate is slightly soluble in acetone and alcohol, but only very slightly soluble in ethyl acetate. It is practically insoluble in benzene, even on heating, and insoluble in chloroform, glycerin, epichlorhydrin, linseed oil, turpentine, and ethyl nitrate. The titration of a solution of fulminate in hydrochloric acid with potassium iodide has been investigated; the mercuric iodide formed first dissolves, but is precipitated on further titration, the line of demarcation being sufficiently definite. Accurate results are obtainable under certain conditions.—W. J. W.

PATENTS.

Explosive. C. Manuelli and L. Bernardini. E.P. 155,627, 17.7.17.

CHLORATES and perchlorates of biguanide and guanidine, prepared by double decomposition of metallic chlorates and perchlorates with salts of biguanide and guanidine, may be used as explosives or constituents of explosive mixtures. Perchlorates of biguanide and guanidine are also obtained by heating a mixture of ammonium perchlorate or chlorate (1 mol.) and dicyanodiamide (2 mols.) to 160°—170° C. The explosives thus prepared, to which oxidising and oxidisable substances may be added, are of good explosive power and possess great stability.—W. J. W.

Guncotton; Process of manufacturing fibrous material, particularly ——. F. A. Wardenburg, Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,355,197, 12.10.20. Appl., 11.12.17.

FIBROUS materials are treated with a liquid in such a manner that the liquid filters through the mass,

and loss of small particles of the material is prevented.—W. J. W.

Smokeless powders; Manufacture of ——. C. Claessen. G.P. 298,859, 11.3.16.

NITROCELLULOSE, together with nitroglycerin, nitroglycol, or nitrated sugar, is mixed with an eutectic mixture of dinitrotoluene and trinitrotoluene, without the aid of a volatile solvent.—W. J. W.

Cellulose; Preparation of material from [wood] —— which is suitable for nitrating and spinning. M. Ellern-Eichmann. G.P. 300,703, 19.3.16.

THE treatment of wood cellulose is carried just so far as to give fibres free from incrustation, which are then washed, centrifuged, and dried without the application of pressure or much heat. The product consists of a mass of uncrushed fibres which may be easily separated, and possess good absorptive properties.—W. J. W.

Guncotton; Apparatus for purification of ——. H. Eicheler. G.P. 323,036, 16.9.17.

THE washing vat is provided with two internal sieve plates, into the space between which the guncotton is loaded. The wash water enters the bottom of the vat, which is funnel-shaped, and passes upwards through the sieve plates and the material to an overflow at the top. In order to effect complete purification of the smallest particles, the rate of flow of the water is varied periodically, thus ensuring alternate saturation and draining.—W. J. W.

Delay fuses; Manufacture of ——. F. Israel. G.P. (A) 324,004, 23.1.17, (B) 324,005, 13.7.18, and (C) 324,006, 24.10.18.

(A) NITROCELLULOSE is incorporated with finely-divided charcoal or similar material and an oxygen carrier, such as potassium nitrate, and formed into porous sticks, which are then covered with a layer of an incombustible, or not easily combustible, substance, such as cellulose acetate, and, if desired, enclosed in metal tubes. These fuses are impervious to damp, and burn slowly and uniformly. (B) The nitrocellulose may be used in the form of grains or flakes, pressed into metal or paper tubes. The time of combustion is approximately three times as long as with gunpowder fuses. (C) By omitting the charcoal from the composition, and adding only 1—3% of potassium nitrate, the flakes or grains being then graphitised and pressed into metal or paper tubes, a still slower rate of combustion is obtained. —W. J. W.

Cellulose and cotton waste; Process and apparatus for drying vegetable materials, especially —— before nitration. Westfälisch - Anhaltische Sprengstoff A.-G. G.P. 326,303, 20.2.18.

THE material is drawn by a fan into a tunnel with heated walls, from which it is then blown direct to the storage chambers in connexion with the nitrating plant.—W. J. W.

Nitrated material; Process and apparatus for continuous steaming of ——. I. M. Voith. G.P. 326,304, 26.9.18.

THE material is passed continuously through a closed receptacle in which it is subjected to treatment with steam.—W. J. W.

Damp-proof matches; Process for producing ——. R. Dubrisay. U.S.P. 1,363,095, 21.12.20. Appl., 29.6.20.

As an agglutinant in the paste, a reaction product prepared from an aldehyde and resorcinol, in presence of a catalyst, is employed.—W. J. W.

XXIII.—ANALYSIS.

Crucibles used in rock analysis [; Gold-palladium alloy as material for ——]. H. S. Washington. J. Wash. Acad. Sci., 1921, 11, 9—13.

APART from the question of cost, a disadvantage in the use of platinum and iridium-platinum crucibles is the difficulty of completely removing the melt after fusion of silicates with sodium carbonate. In experiments with a crucible of "palau" (gold 80%, palladium 20%), the cake obtained after sodium carbonate fusions could be completely and easily removed by treatment with hot water, even when the crucible was indented. Determinations of the loss in weight of crucibles of "palau" and iridium-platinum indicated an average loss, after 47 fusions, of 0·2 mg. with "palau," and with iridium-platinum, after 21 fusions, of 0·5 mg. In the latter case the loss is partly due to volatilisation of iridium.—W. J. W.

Electric furnace for use in the determination of arsenic by the Marsh method. L. Birckenbach. Chem.-Zeit., 1921, 45, 61—62.

A SMALL electric furnace for heating the arsenic-mirror tube consists of a kieselguhr brick provided with a groove for holding the tube and fitted with a heating spiral of nickel-chrome wire; the cover of the furnace is also made of kieselguhr, and is divided into two pieces. An alloy of zinc, 500, and copper, 0·625 g. is recommended for use in the hydrogen generation flask in place of ordinary granulated zinc.—W. P. S.

Indicator; A new ——. R. W. Kinkead. Chem. News, 1921, 122, 4—5.

A NEW indicator of at present unknown constitution, pink in acid, and blue in alkaline media, is formed by the action of ethyl nitrate (1 mol.) on magnesium phenyl bromide (1 mol.) in ethereal solution. The substance is isolated by separating the ethereal layer, evaporating off the ether, adding sodium carbonate and water to the residue, and extracting with chloroform. The blue sodium salt remains in the aqueous layer. It is, however, somewhat unstable, and the indicator is best kept as an ethereal solution of the free acid. Neither the aqueous solution of the free indicator nor that of the sodium salt can be concentrated without decomposition.—G. F. M.

Acidity in coloured solutions; Titration of ——. B. G. Hartmann. J. Assoc. Off. Agric. Chem., 1920, 3, 410—411.

A MIXTURE of sodium sulphate, 50, and phenolphthalein, 1 g., finely powdered, is recommended for use as external indicator in the titration of strongly coloured acid solutions; drops of the solution are placed on the powder.—W. P. S.

Adsorption in analytical chemistry. Part. IV. Adsorption of alkalis by cellulose. I. M. Kolthoff. Pharm. Weekblad, 1921, 58, 46—56. (*Cf.* J., 1921, 63 A.)

WITH sodium and potassium hydroxides no real adsorption occurs, the quantities taken up being proportional to the end concentrations for solutions up to 4*N*. Between 4*N* and 6*N* the quantity taken up is constant, indicating chemical combination; a sudden increase occurs at about 6*N*, the quantity then remaining constant again. The alkali carbonates are not taken up at all. Barium hydroxide is taken up in amounts proportional to the square roots of the end concentrations. Ammonia is taken up in constant quantity in presence of traces of other alkalis. (*Cf.* J.C.S., Mar.)—S. I. L.

Adsorption in analytical chemistry. Part V. Adsorption of salts of the alkali and alkaline-earth metals and of alkaloids by filter paper. I. M. Kolthoff. Pharm. Weekblad, 1920, 58, 94—101.

PRACTICALLY no adsorption was found for any salts of the alkali or alkaline-earth metals, or for morphine hydrochloride. With quinine hydrochloride and strychnine nitrate small quantities were taken up in exact agreement with the adsorption equation. (*Cf.* J.C.S., Mar.)—S. I. L.

Nitrates; Removal of —— [in analysis] by means of alcohol. R. Schneidewind. Chem. and Met. Eng., 1921, 24, 22.

IN analytical processes which require the absence of nitric acid or nitrates, their removal may be more conveniently effected by means of ethyl alcohol than by the usual method of evaporating with sulphuric acid. For example, to a solution containing 20 c.c. of nitric acid and 150 c.c. of water, 15 c c. of sulphuric acid is added, and when nearly boiling 5 c.c. of ethyl alcohol is carefully run in from time to time, until further addition no longer causes an evolution of nitrous fumes. The boiling is then continued to expel the excess of alcohol and the resulting solution is sufficiently free from nitric acid no longer to give the brown ring test, or to oxidise hydrogen sulphide.—G. F. M.

Potassium; Separation and determination of —— [as perchlorate]. S. B. Kuzirian. J. Assoc. Off. Agric. Chem., 1920, 3, 321—323.

ANILINE perchlorate is recommended for use in place of perchloric acid; a known weight of the perchlorate is dissolved in 50 c.c. of absolute alcohol, and this solution is added slowly to the mixed chloride solution. For each 1·5 c.c. of water used to dissolve the mixed chlorides, 50 c.c. of absolute alcohol should be added. Sulphates, if present, must be removed previously with barium chloride; the excess of barium chloride does not interefere.
—W. P. S.

Nitrogen; The Kjeldahl method for determining ——. I. K. Phelps and H. W. Daudt. J. Assoc. Off. Agric. Chem., 1920, 3, 306—315.

THE method yielded trustworthy results in the case of amines, and pyrrolidine, pyridine, piperidine, quinoline, purine, glyoxaline, quinoxaline, quinazolone, etc. derivatives, provided that mercuric oxide and potassium sulphate were added to the acid digestion mixture. In the case of azo compounds, a preliminary reduction by boiling with stannous chloride in alcoholic solution was necessary. Hydrazine compounds required boiling with formaldehyde, zinc dust, and hydrochloric acid in alcoholic solution, with subsequent addition of stannous chloride before digestion with sulphuric acid, mercuric oxide, and potassium sulphate.
—W. P. S.

Volumetric analysis. [Determination of mercuric chloride, chloroform, and lead.] O. Sasse. Pharm. Zeit., 1920, 65, 559, 688.

METHODS are described for the titration of mercuric chloride (with potassium iodide), chloroform (decomposition with potassium hydroxide and estimation of the potassium chloride formed), and lead salts (with potassium bichromate). In the case of mercuric chloride tablets, the red colouring matter which is usually present may be destroyed by treatment with chlorine previous to titration with potassium iodide.—W. P. S.

PATENTS.

Cereals or other substances; Apparatus for indicating moisture in ——. Soc. Anon. des Grands Moulins Vilgrain, and M. Chopin. E.P. (A) 143,191, 4.2.20, and (B) 155,486, 25.2.20. Conv., 9.5 and 20.12.19.

(A) THE cereal is introduced in regulated quantity into a heated vertical chamber and then discharged from the same. The amount of water vapour produced is measured by the maximum pressure produced; means are provided for discharging the vapour periodically, and it may be passed to a condenser and the amount of condensed water measured. (B) The cereal is passed downwards through a vertical bronze tube surrounded by an iron tube and provided with an electrical heating jacket. The water vapour from the heated cereal passes through orifices in the bronze tube into the space between the two tubes and escapes thence into a condenser provided with a constant water supply. The difference in temperature of the water entering and leaving the jacket of the condenser is a measure of the amount of water vapour given off by the cereal. The rate of flow of the cereal through the tube is controlled by valves. (*Cf.* J., 1920, 797 A.)—W. P. S.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Arnold, and Goldschmidt A.-G. Carrying out to the limit incompletely-proceeding reactions. 3704. Jan. 31. (Ger., 7.2.20.)

Barbet et Fils et Cie. Evaporating apparatus. 3373. Jan. 27. (Fr., 27.1.20.)

Berk and Co., and Briscoe. Separating solids by crystallisation from solvents. 3848. Feb. 1.

Bibb. Furnace or kiln. 3496. Jan. 28.

Cleworth, Wheal and Co., and Leask. Purification or treatment of air or gas with liquid. 3125. Jan. 25.

Davis. Treating materials in the gaseous phase. 3256. Jan. 26.

Hurrell and Johnson. Rotary filter. 4132. Feb. 4.

Newton. Drying cylinders etc. 4271. Feb. 5.

Paterson. Filtering apparatus etc. 3675. Jan. 31.

Thorssell and Troell. Agglomerating pulverous material. 3965. Feb. 2.

Weyel and Zimmermann. Drying apparatus. 4059. Feb. 3.

Zack. Obtaining a vacuum by the liquefaction of gases. 4014. Feb. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

21,323–4 (1918). Francart. Tunnel furnaces, kilns, ovens, etc. (157,474–5.) Feb. 2.

24,371 (1919). Ruff. Heat treatment or evaporation of liquids. (157,514.) Feb. 2.

25,708 (1919). Martinez. Mechanical mixing machines. (157,557.) Feb. 2.

3894 (1920). Elmore. Centrifugal driers. (158,152.) Feb. 9.

16,857 (1920). Sharples. Centrifugal machines. (157,688.) Feb. 2.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Accioly. Treatment of mineral etc. oils. 3594. Jan. 29.

Bibb. Composition for briquettes etc. 3498. Jan. 28.

Demant. Process for refining hydrocarbons. 4136. Feb. 4.

Dobson and Mossop. Preparation of liquid fuel. 3634. Jan. 31.

Fabry. Purifying coal gas. 4007. Feb. 3.

Farrant. Production of colloidal fuel. 3851. Feb. 1.

Fletcher. Utilisation of peat etc. for steam production. 3114. Jan. 25.

Halbergerhütte. 3238. *See* X.

Illingworth. Coking coal. 3923. Feb. 2.

Kneen. Water-gas plant. 3109. Jan. 25.

Maus. Drying and pressing peat into shape. 3823. Feb. 1.

Torfverwertungs Ges. Pohl u. von Dewitz. Dry distillation and coking of raw peat etc. 2978. Jan. 24. (Ger., 22.1.20.)

Trent Process Corp. Production of coke. 4187. Feb. 4. (U.S., 21.2.20.)

Wilton. Utilising waste gases from furnaces etc. for extracting by-products from coal etc. 3407. Jan. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

12,509 (1918). Garrow. Low and medium temperature carbonisation of coal, shale, wood, peat, etc. (158,002.) Feb. 9.

18,038 (1919). Broadbridge and others. *See* XII.

4591 (1920). Melamid. Manufacture of transformer oil. (143,193.) Feb. 9.

17,763 (1920). Miles. Manufacture of paraffin wax emulsions. (145,602.) Feb. 9.

III.—TAR AND TAR PRODUCTS.

APPLICATIONS.

Bawden, Bennett, and United Alkali Co. Manufacture of *o*- and *p*-nitrophenol. 3369. Jan. 27.

Bawden, Bennett, and United Alkali Co. Separation of *o*- and *p*-nitrochlorobenzenes from mixtures thereof. 3370. Jan. 27.

Demant. 4136. *See* II.

Prager, and South Metropolitan Gas Co. Manufacture of naphthalene compounds. 3032. Jan. 24.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

APPLICATIONS.

Addy, and British Cellulose and Chem. Manuf. Co. Manufacture or treatment of articles made of plastic materials. 3902. Feb. 2.

Bernot and Fournier. Manufacture of paper pulp. 3828. Feb. 1.

Bloxam (Akt.-Ges. f. Anilinfabr.). Protecting animal fibres in treating them with alkaline liquids. 3377. Jan. 27.

Cew and Marx. 3898. *See* XIII.

Duclaux. Treatment of cellulose esters. 3742. Feb. 1.

Joliot. Manufacture of cellulose threads. 4191. Feb. 4. (Fr., 30.8.20.)

Schwartz. Manufacture of cellulose acetate and artificial silk therefrom. 3296. Jan. 27.

Sutcliffe. Preparation of vulcanised fibre. 3320. Jan. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

21,172 (1919). Goldschmidt. Process of degumming silk. (131,906.) Feb. 2.

16,075 (1920). Glanzfäden A.-G. Preparing durable cupric ammonia cellulose solutions for spinning artificial thread etc. (145,035.) Feb. 9.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

APPLICATIONS.

Bloxam (Akt.-Ges. f. Anilinfabr.). 3377. *See* V.

Briggs, Richardson, and British Cellulose and Chem. Manuf. Co. Dyeing. 3347. Jan. 27.

Calico Printers' Assoc., and Costobadie. Production of ornamental effects on fabrics. 3486. Jan. 28.

Calico Printers' Assoc., and Nelson. Ornamentation of textile fabrics. 4073. Feb. 9.

Tate. Process for dyeing and waterproofing. 3198. Jan. 26.

Whitaker and Whitaker. Machines for dyeing, scouring, and washing wool etc. 3172. Jan. 26.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

APPLICATIONS.

Barnett. Production of chemical compounds or elements by gravitational translation of amalgam formed by electrolysis to hermetically sealed receptacle. 3171. Jan. 26.

Freeth and Munro. Production of ammonium chloride and sodium carbonate. 2921. Jan. 24.

Niccoli. Production of hydrochloric acid by direct synthesis. 3104. Jan. 25. (Ital., 2.3.20.)

Parrish, and South Metropolitan Gas Co. Manufacture of ammonium sulphate. 3033. Jan. 24.

Soc. l'Air Liquide. Synthesis of ammonia. 3949. Feb. 2. (Fr., 2.2.20.)

Wade (Lindsay Light Co.). Manufacture of thorium compounds. 4100. Feb. 3.

COMPLETE SPECIFICATIONS ACCEPTED.

25,544 (1919). Mackay. Making lead sulphate direct from lead sulphide ores. (157,554.) Feb. 2.

26,332 (1919). Armour Fertilizer Works. Production of aluminium nitride. (146,919.) Feb. 9.

10,751 (1920). Soc. l'Air Liquide. Production of hydrogen peroxide. (141,758.) Feb. 9.

VIII.—GLASS; CERAMICS.

APPLICATIONS.

Ferguson. Manufacture of sheet glass. 3144. Jan. 25.

Marlow. Ovens or kilns for manufacture of tiles, pottery, etc. 3526, 3580–1. Jan. 29.

COMPLETE SPECIFICATIONS ACCEPTED.

27,438 (1919). Frink. Manufacture of sheet glass. (157,598.) Feb. 2.

16,191 (1920). Truel. Glass-melting tanks or furnaces. (157,684.) Feb. 2.

IX.—BUILDING MATERIALS.

APPLICATIONS.

Lyon. Process for drying wood. 3950. Feb. 2.

Marks. Concrete. 3975. Feb. 3.

Newberry. Manufacture of cement. 3707. Jan. 31.

Winkler. Manufacture of mortar, cement, etc. 3783. Feb. 1. (Switz., 26.7.20.)

Winkler. Cement, mortar, concrete, etc. 3903–4. Feb. 2. (Switz., 30.8 and 15.10.20.)

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

APPLICATIONS.

Alexander. Nickel alloy. 3306. Jan. 27.

British Thomson-Houston Co. (General Electric Co.). Alloys. 4088. Feb. 3.

Fairweather (Avesta Jernverks Akt.). Producing silicon-manganese-chrome steel. 3672. Jan. 31.

Fehr and Fehr. Electrodeposition of bronze etc. 3097. Jan. 25.

Fletcher. Smelting, melting, and refining metal in furnaces using air blast. 3108. Jan. 25.

Freedman and Greetham. Extraction of metals from their compounds. 3159. Jan. 26.

Goldschmidt A.-G. Bearing metal alloy of high lead content. 3251. Jan. 26. (Ger., 26.1.20.)

Gunderson. Process of case-hardening copper. 3715. Jan. 31.

Halbergerhütte Ges. Purification of blast-furnace etc. gases. 3238. Jan. 26. (Ger., 23.3.20.)

Hale. Production of malleable iron castings. 4072. Feb. 3.

Iytaka. Alloys. 3487. Jan. 28.

Lowe. Soldering aluminium. 2918. Jan. 24.

Pacz. Alloys, and process of treating same. 3260. Jan. 26. (U.S., 13.2.20.)

Rheinisch-Nassauische Bergwerks- u. Hütten A.-G., and Spieker. Production of zinc dust having a high percentage of metallic zinc. 3481. Jan. 28. (Ger., 22.11.20.)

Rosthorn. Manufacture of copper alloys. 4230. Feb. 4. (Ger., 4.2.20.)

Trent Process Corp. Treating ore etc. 4188. Feb. 4. (U.S., 21.2.20.)

Trent Process Corp. Collecting and purifying minerals. 4189. Feb. 4. (U.S., 9.4.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

17,909 (1919). Armstrong. Stable surface alloy steel. (143,829.) Feb. 2.

18,498 (1919). Thompson, Ltd., Thompson, and Partridge. Coating iron, steel, and certain other metals with aluminium. (158,010.) Feb. 9.

25,544 (1919). Mackay. See VII.

25,546 (1919). Mackay. Recovery of vanadium from its ores. (157,555.) Feb. 2.

32,093 (1919). Schafer and Brettschneider. Case-hardening mixtures for iron and steel. (157,639.) Feb. 2.

5722 (1920). Hall, and Rolls-Royce, Ltd. Preparation of alloys and refining metals and alloys. (158,156.) Feb. 9.

24,670 (1920). Russell, and Manchester Furnaces, Ltd. Heat-treatment furnaces. (157,696.) Feb. 2.

XI.—ELECTRO-CHEMISTRY.

APPLICATIONS.

Automatic Telephone Manuf. Co., Ltd., and Roseby. Electric furnaces. 4247. Feb. 5.

Barnett. 3171. *See* VII.

Fehr and Fehr. 3097. *See* X.

Pouchain. Negative electrode for electric accumulators. 3378. Jan. 27.

COMPLETE SPECIFICATION ACCEPTED.

32,790 (1919). Levin. Electrolytic gas generators. (158,148.) Feb. 9.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Bitterling, Lyman, and Bitterlings, Ltd. Apparatus for rendering fats, drying, sterilising, or destroying animal matter. 3586. Jan. 29.

Fankhauser. Squeezing oils and fats from oily and fatty substances. 3922. Feb. 2. (Switz., 3.2.20.)

Green. 3741. *See* XIX.

Tempelhoff. Medicated antiseptic soap. 2946. Jan. 24.

COMPLETE SPECIFICATIONS ACCEPTED.

18,038 and 19,797 (1919). Broadbridge, Edser, and Minerals Separation, Ltd. Treatment of emulsions and the like. (157,490.) Feb. 2.

6239 (1920). Boehringer Sohn. Manufacture of soaps and washing-materials. (139,776.) Feb. 2.

13,582 (1920). Wade (Wilson and Co.). Process for compounding fats and oils. (158,175.) Feb. 9.

15,882 (1920). Elektro-Osmose A.-G. Process for decolorising liquids containing glycerin or crude glycerin. (144,727.) Feb. 2.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATION.

Cew and Marx. Preparation of dilute solutions of resin soap. 3898. Feb. 2.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Davidson. Treatment of rubber etc. 4306. Feb. 5.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Hayward. Apparatus for drying gelatin etc. 3896. Feb. 2.

Schidrowitz. Adhesives. 3388. Jan. 27.

COMPLETE SPECIFICATIONS ACCEPTED.

16,743 (1920). McQuitty. Manufacture of sheets of edible gelatin. (145,486.) Feb. 9.

19,827 (1920). Devoz. *See* XVI.

XVI.—SOILS; FERTILISERS.

COMPLETE SPECIFICATIONS ACCEPTED.

17,608 and 17,720 (1920). Akt.-Ges. f. Anilinfabr. Manufacture of artificial fertilisers. (146,259 and 145,582.) Feb. 9.

19,827 (1920). Devoz. Manufacture of soluble nitrogenous manures from waste leather and other animal detritus. (147,798.) Feb. 9.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Bitterling and others. 3586. *See* XII.

Dick, and International Dry-Milk Co. Dehydrated milk. 4208. Feb. 4.

Green. Purification and deodorisation of sewage oil or grease. 3741. Feb. 1.

Smith. Concentrated coconut milk. 4074. Feb. 3.

Smith. Coconut food products. 4075. Feb. 3.

Trent. Sewage process. 3420. Jan. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

24,915 (1919). McDougall and Howles. Sheep and cattle dips and washes. (157,527.) Feb. 2.

26,785 and 31,759 (1919). Brock. Baking-powder or self-raising flour. (157,581.) Feb. 2.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Chem. Fabr. auf Actien, vorm. E. Schering. Manufacture of diethylbarbituric acid compound. 3138. Jan. 25. (Ger., 26.1.20.)

Douse, and United Alkali Co. Manufacture of ethyl chloroformic ester. 3371. Jan. 27.

Metcalfe and Usher. Extracting essential oils etc. 3995. Feb. 3.

COMPLETE SPECIFICATION ACCEPTED.

26,700 (1919). Sidgwick, Plant, and Boake, Roberts, and Co. Preparation of diethyl sulphate. (157,578.) Feb. 2.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Brandenberger. Production of sensitive photographic films. 3252. Jan. 26.

Brandenberger. Photographic films with a carrier permeable to water. 3253. Jan. 26.

Soc. Anon. La Cellophane. Preparation of photographic films permeable to water. 2981. Jan. 24. (Fr., 19.4.20.)

Sperati. Photography. 3817–8. Feb. 1. (Ital., 17 and 16.10.20.)

COMPLETE SPECIFICATION ACCEPTED.

23,910 (1919). Donisthorpe, and Dye Impression Photos, Ltd. Processes of dye transfer printing from photographic negatives. (158,021.) Feb. 9.

I.—GENERAL; PLANT; MACHINERY.

Soot and sulphur compounds; Formation of —— in boiler plants. E. Donath. Brennstoff-Chem., 1921, 2, 26—28.

The chemical character of soot and of the sulphur compounds of flue gases is discussed, also their corrosive effects on ironwork in the cooler parts of the plant. These are most formidable in the products from such fuels as the Arsa coal of Istria, which contains 10% of sulphur. When thrown upon a hot fire this evolves at first large volumes of hydrogen sulphide, which attacks even the iron of the fire doors with the formation of ferrous sulphide. The flue dust contains sulphides, and is also corrosive. Some advantage is gained by admixture of lime and bog iron ore, but it is concluded that such coal is unsuitable for boiler firing. As the coal gives a large yield of low-temperature tar in a suitable gas producer, its gasification is suggested, with recovery of sulphur by oxide purification, prior to using the gas as fuel.—H. J. H.

Patents.

Pulveriser and process of fine pulverising. F. Seymour, Assr. to Aero Pulveriser Co. U.S.P. 1,363,361, 28.12.20. Appl., 7.1.19.

A number of rotary beaters are arranged on a horizontal shaft which also carries a fan at one end, and the whole is enclosed in a casing. The beaters decrease in diameter from the fan towards the other end of the series, and the casing is correspondingly stepped. Annular partitions project inwards from the periphery of the casing between the beaters, and the material is carried horizontally through the apparatus by the air current.—W. F. F.

Ball mill. H. Sellman. U.S.P. 1,363,620, 28.12.20. Appl., 26.2.20.

A horizontal pulveriser drum is provided with an outlet disc valve on its periphery, having the valve stem projecting outwards through the casing. A space is provided in the wall of the drum between the valve disc and the outer surface of the casing, and the valve spindle is packed where it passes through the latter. The valve disc is cut into sectors and moves over a plate perforated in similar sectors which controls the passage from the drum to the space within the wall.—W. F. F.

Ore-grinding machine. G. W. Morthland. U.S.P. 1,363,990, 28.12.20. Appl., 20.12.18.

Material is admitted through a hollow trunnion to a horizontal grinding drum which gradually increases in diameter towards the outlet end, and the ground material is discharged through the other trunnion. The drum contains a number of transverse discs of equal diameter, but slightly smaller than the smallest diameter of the drum, and increasing in thickness towards the discharge end of the drum. Each disc is provided with a central opening so as to form a continuous passageway through the apparatus, and with radial grooves in their meeting faces. The discs are packed in the drum loosely, so that on rotation they are free to rotate relatively to one another.—W. F. F.

Electro-osmotic separation of substances. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 144,710, 10.6.20. Conv., 8.4.18.

In the electro-osmotic separation of substances consisting of dispersoids, such as suspension or emulsion colloids, ions and non-ionised substances, ions suitable for the purpose of electro-osmosis are substituted for ions unsuitable for this purpose in the mixture under treatment. In the purification of albumin solutions containing ammonium sulphate, for example, the ammonium ions migrate more quickly than the SO_4-ions, with the result that the solution in the middle compartment of the electro-osmotic cell becomes acid and albumin is precipitated. In such case the SO_4-ion is preferably replaced by the anion of acetic acid by addition of barium acetate and removal of the precipitated barium sulphate. In like manner univalent ions can be exchanged for other univalent ions, and multivalent anions replaced by suitable organic or inorganic anions of the same or different valency. —J. S. G. T.

Metal [heat] regenerators. M. Mathy. E.P. 147,035, 6.7.20. Conv., 4.6.18.

The regenerator is constructed of metal tubes of small diameter supported on slabs or arches of refractory material to prevent buckling.—B. M. V.

Furnace reaction chamber and method of preventing destruction thereof. F. J. Metzger, Assr. to Air Reduction Co., Inc. U.S.P. 1,363,428, 28.12.20. Appl., 6.2.20.

Nichrome tubes which are used in carrying out high temperature reactions by external heating with oxidising gases are protected by an internal coating of nickel.—W. F. F.

Annealing oven. S. J. Booth, J. Terreault, and W. L. Burn. U.S.P. 1,364,694, 4.1.21. Appl., 20.6.19.

A brickwork chamber is divided by a partition into a firebox compartment and an oven compartment. The walls, roof, etc., of the latter are double, the spaces between forming flues through which the burning gases from the firebox are led as follows:—Along the roof, down the end wall, along the bottom, up the partition wall, along the top part of the side walls, back along the bottom part of the side walls to the exhaust flue.—B. M. V.

Salts; Means for drying ——. South Metropolitan Gas Co., and P. Parrish. E.P. 156,963, 14.11.19.

In a drying apparatus of the kind in which the salt falls in a shower down a tower through which an upward current of hot gases is maintained, the tower is provided with distributing cones at different levels; baffle bars of triangular cross-section are disposed between the cones; devices are provided for directing on to the next cone the salt which has been distributed by the preceding one; and the surfaces which receive the descending salt are subjected to continuous or intermittent vibration.—W. E. F. P.

Drying apparatus. W. H. Perry, Assr. to Normandy Sea Food Co. U.S.P. 1,363,431, 28.12.20. Appl., 26.12.18.

A conduit through which a conveyor passes is arranged just above another conduit through which warm air is forced. A number of communicating passages are provided so that regulated quantities of warm air may be admitted into the conveyor conduit and through the conveyor.—W. F. F.

Drying liquids and the like; Method of ——. P. Müller. U.S.P. 1,364,403, 4.1.21. Appl., 26.8.13. Renewed 28.5.20.

Liquid is finely subdivided and projected horizontally across a drying chamber in a flat lamina. A drying medium is also projected horizontally, in the same direction, over the top and bottom surfaces of the lamina, and is maintained in contact therewith until the particles are dried.—W. F. F.

Drying apparatus. O. Müller. U.S.P. 1,364,402, 4.1.21. Appl., 25.8.20.

A drying apparatus comprises a number of trucks

placed end to end and divided by horizontal partitions so as to form several superposed continuous conduits. Hot air is blown at one end into all the conduits except the uppermost, and the air passes at the other end into the uppermost conduit, through which it passes back to the outlet. —W. F. F.

Heater [for obtaining hot air with reduced oxygen content]. J. McC. Selden, Assr. to The Selden Co. U.S.P. 1,352,481, 14.9.20. Appl., 12.2.18.

THE heater consists of a chamber with a baffle wall in the middle, this wall being vertical on one side and stepped on the other. A flame is projected into the chamber against the lower broader end of the stepped side of the baffle wall. Air passed through the chamber, upwards over the stepped side of the baffle wall and then downwards over the other side, can be rapidly heated to any temperature from 150° to 1000° C., and at the same time its oxygen content can be reduced to 14%, thus rendering it suitable for use in the catalytic oxidation of naphthalene to phthalic anhydride (*cf.* E.P. 119,517—8; J., 1918, 684 A) without the risk of producing readily explosible mixtures.

Emulsifier. C. B. Dalzell, Assr. to D. H. Burrell and Co. U.S.P. 1,363,572, 28.12.20. Appl., 24.11.19.

A CYLINDRICAL vessel is carried at one end of a horizontal shaft, and liquid is admitted axially into its open end from a fixed tank. The liquid is discharged over the edge by centrifugal force into a second annular vessel, and from that vessel into the surrounding casing. The shaft is packed so as to prevent the admission of air into the casing. —W. F. F.

Gases; Apparatus for bringing about and controlling reactions between ——. C. Conover. U.S.P. 1,363,955, 28.12.20. Appl., 30.4.19.

A REACTION chamber for gases consists of a sinuous pipe within a casing. The casing is provided with partitions which extend from each side wall alternately and cause air which is passed through the chamber to follow the bends of the pipe.—W. F. F.

Gases; Process of and apparatus for treating mixed ——. C. S. Palmer. U.S.P. 1,364,136, 4.1.21. Appl., 28.10.18.

A MIXTURE of two gases, one of which is more susceptible to magnetisation than the other, is passed over and through a porous magnetised screen. The gases are withdrawn in two streams at opposite sides of the screen, one of the streams being enriched with the more magnetisable gas.—W. F. F.

Mixing apparatus. R. W. Shafor, Assr. to The Dorr Co. U.S.P. 1,364,412, 4.1.21. Appl., 26.7.16.

AN apparatus for mixing liquid with a gas comprises a closed container having a lateral outlet for the treated liquid, and a vertical conduit extending from the lower end to a point above the liquid level. The gas is forced under pressure into the lower end of the conduit so as to form a gas-lift. Excess gas is returned from the gas space above the liquid and returned to the gas-supply pipe between the source of supply and the compressor.

Pulverulent material; Means for preparing and conveying ——. W. O. Amsler. U.S.P. 1,364,603, 4.1.21. Appl., 3.4.16.

MATERIAL is pulverised between crushing rolls and a horizontal table which is heated so as to dry the material. The material is withdrawn by means of a pipe which is moved over the surface of the table. Suction is applied to the pipe so as to draw preheated air into the casing and thence to the open end of the pipe.—W. F. F.

Extracts; Apparatus for making ——. T. P. Tuite. U.S.P. 1,365,068, 11.1.21. Appl., 8.5.17.

A RESERVOIR for the extracting medium communicates with a container for pulverised material through an opening that can be adjusted by changing the position of the reservoir.—B. M. V.

Photochemical apparatus. W. O. Snelling. U.S.P. 1,365,740, 18.1.21. Appl., 22.11.16.

THE apparatus consists of a series of transparent vessels, each having an inlet and an outlet, and provided with screens which are adjustable independently.—W. E. F. P.

Separating the constituents of air or other gaseous mixtures; Apparatus and method for ——. R. Wucherer and F. Pollitzer, Assrs. to The Linde Air Products Co. U.S.P. 1,360,853, 30.11.20. Appl., 29.12.14.

SEE E.P. 24,735 of 1914; J., 1915, 871.

Kiln. F. Fidler and J. G. Maxwell. U.S.P. 1,364,090, 4.1.21. Appl., 27.12.19.

SEE E.P. 141,124 of 1919; J., 1920, 408 A.

Rotary apparatus for treating loose material with gaseous fluids. A. Gerlach. U.S.P. 1,364,105, 4.1.21. Appl., 6.3.20.

SEE E.P. 133,327 of 1919; J., 1920, 143 A.

Filtering or dewatering press. A. ten Bosch, Assr. to Naaml. Vennoots. Nederlandsche Veenverwerking Maatschappij. U.S.P. 1,366,307, 18.1.21. Appl., 24.4.20.

SEE E.P. 154,817 of 1920; J., 1921, 71 A.

Crushing and pulverising machines. J. E. Kennedy. E.P. 139,219, 20.2.20. Conv., 2.2.14.

Casings for glass containers. E.P. 131,918. *See* V.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Mineral matter in coal; Distribution of ——. R. Lessing. Inst. Min. Eng., Jan. 22, 1921. [Advance proof.]

SAMPLES of colliery slack were subjected to elutriation with an upward current of water; the dust was first removed from the surface of the slack by the action of a slow current, and the coal subsequently freed from the "dirt" by increasing the speed of the current, the coal overflowing and the dirt remaining behind. The ash content of the dust thus collected was generally about 20%, whilst that of the coal varied from 1·44 to 1·98% and that of the dirt from 28·95% to 54·69%. The ash contributed to the entire sample by the dust was at least equal to, and in some cases more than twice as much as that contributed by the whole bulk of the clean coal, although the dust portion itself only ranged from 6 to 9% of the bulk of the sample. The ash was separated into water-soluble, acid-soluble, and acid-insoluble portions, and each of these portions was separately examined. In a Staffordshire coking slack the water-soluble portion of the ash from the dust amounted to 2·44%, of the ash from the clean coal to 3·48%, and of the ash from the dirt to 3·70%; the acid-soluble portion of the ash from the dust was 23·72%, of that from the clean coal, 50·50%, and of that from the dirt, 38·96%, whilst the acid-insoluble portion of the ash from the dust amounted to 73·84%, of the ash from the clean coal to 46·02%, and of the ash from the dirt to 57·34%. The ash in light clean coal decreases with the size down to 30-mesh, with an increase in the portion through 30-mesh, the latter doubtless due to its containing fusain dust; whilst that of the durain

portion shows a decrease down to 20-mesh, followed by an increase in the smaller size. The ash in the dirt consistently increases with decreasing size. In the float-and-sink method of separating coal and "dirt," the author uses as liquid carbon tetrachloride or a mixture of this with light petroleum spirit.—A. G.

Coal examination; A simplified method of ——. M. Dolch. Mitt. Inst. Kohlenvergasung, 1921, 3, 1—6.

The dried coal is heated in a transparent quartz tube, inserted in an electric furnace wound with nichrome wire, and lagged with kieselguhr, this being retained in place by asbestos cord, painted over with sodium silicate. The determinations of coke, moisture, ash, tar yield, and quality and quantity of gas are all made in one apparatus. To avoid partial combustion the carbonisation is carried out in an atmosphere of nitrogen or carbon dioxide. The passage of a current of dry air over the tar in a special apparatus greatly accelerates the drying of the tar. The production of tar fog is avoided by slow heating and the use of dried coal. Moisture is estimated by attaching a tube containing calcium chloride saturated with carbon dioxide and weighing before and after a period of one hour during which time the temperature is maintained at 105° C. and a current of carbon dioxide is passed through the tube. Coke is estimated by carbonisation at 800° C. for half an hour, the carbonisation tube being weighed before and after the experiment. The weight of tar plus gas liquor can be obtained from the weight of the tar tube, and by subsequent drying the percentages of water of constitution and anhydrous tar are obtained.—A. G.

Carbon dioxide in coal; Determination of ——. F. S. Sinnatt and W. Harrison. Bull 7, Lancs. and Ches. Coal Research Assoc., 1920, 15 pp.

The sample of coal is pulverised to pass through a 1/90-mesh sieve, and from 0·5 to 5 g. is introduced into the decomposition flask of the apparatus described previously (Analyst, Apr., 1913). The coal is covered with about twice its volume (5 to 15 c.c.) of distilled water, and is then gently heated, the contents being open to the air, until the water commences to boil, and maintained at a gentle simmer for about 20 mins. The carbonates in the coal are decomposed with hydrochloric acid (5%) or phosphoric acid (syrupy acid diluted 4 times), and the carbon dioxide is carried over by a constant current of air into a collecting vessel, where it is estimated by Pettenkofer's method.—W. P.

Coke ovens; Pyrogenic decompositions in ——. A. Thau. Brennstoff-Chem., 1920, 1, 52—58, 66—68.

Carbonisation trials with laboratory and small-scale apparatus are not likely to furnish the same results as large-scale plant, particularly as regards the secondary pyrogenic reactions. The author has therefore made observations on a single coke oven in a working battery carbonising Durham coal. The products from this were isolated from the rest, the crude gas being drawn through a small cooling and washing plant consisting of a train of oil casks and then collected for analysis in a small holder. The temperature of the oven wall at charging was varied and measured, as also the temperature attained at the oven arch. After determining the nature of the products at a certain temperature with the oven carefully sealed, a quantity of air (at the higher temperatures, oxygen from cylinders) was drawn in above the charge so as to increase the temperature of the arch by 100°—160° C. Oxygen was used to avoid the disturbing influence of nitrogen on the results. The nature of the crude gas and products then drawn from the oven was again determined. In this way the effect of in-drawn air due to "overpulling" could be determined under various conditions of carbonisation. The "low temperature" character of the products of carbonisation at 500° C. became less marked as the initial wall temperatures were raised. The effect of in-drawn air at 500°—800° was not serious; it acted merely as a diluent. Above 900° the products were essentially of a "high temperature" character. The crude benzol showed traces only of paraffins and the gas contained traces of naphthalene. No serious decomposition of ammonia was apparent even at 1000° in the absence of oxygen, but the naphthalene increased at the expense of the benzol. By an experiment on a charge of three-quarters the normal size it was shown that the effect of an empty space was less than that due to contact with glowing carbon. In general the decompositions were not serious even at the highest temperature until oxygen was admitted. Then a rapid loss of ammonia was observed, naphthalene was formed at the expense of the benzol, and the tar became thicker. The author concludes that the induction of air during carbonisation is the main cause of degradation of products, and therefore that a negative pressure in gas retorts and coke ovens is to be avoided as far as possible.

—H. J. H.

Air factor; Calculation of the —— [*during combustion*]. A. B. Helbig. Feuerungstech., 1921, 9, 53—58.

A method is worked out for the calculation of the air requirements of liquid and gaseous fuels from an analysis of the flue gases with the aid of a triangular diagram (*cf.* Ostwald, J., 1919, 492 A).

—W. P.

Gas producers; Use of steam for cooling the fuel bed of ——. H. Koschmieder. Brennstoff-Chem., 1921, 2, 23—26.

In a previous communication (*cf.* J., 1921, 111 A) it was shown that 766 kg.-cals. of heat must be absorbed per 1 kg. of carbon gasified to reduce the temperature of the bed to 1000° C. when cold air blast is used. This may be done by the injection of steam which is effective either by the absorption of heat in water-gas production or by increase of the sensible heat of the steam. The necessary heat would be absorbed by 0·409 kg. of steam if completely decomposed, or by 1·974 kg. if no decomposition occurred. The author has worked out and tabulated the effects of additions of steam between these limits on the quantity, composition, and calorific value of the gas, and the efficiency of its production, both when the air blast is cold and heated to 500° C. He has further calculated and tabulated the results of such additions on the efficiency of the gases in use when burnt under different conditions, *e.g.*, with and without recuperation.—H. J. H.

Wood and wood waste; Gasification of —— *in producers*. Gwosdz. Brennstoff-Chem., 1920, 2, 21—23.

It is necessary to remove moisture from wood gas to secure high flame temperatures, and tarry matter if the wood gas is to be used in gas engines. The latter is specially important, and the methods employed in gas producers of British, French, and American types are described briefly. Two producer plants of German construction are described in more detail. One consists of a producer, into which air is blown below a horizontal grate, and fitted with a bell and charging hopper. Cooling and partial separation of tar and dust are effected in a vertical tower fitted with water spray. Purification is completed in a centrifugal gas cleaner followed by an impact tar separator. The charge of wood waste must be well mixed if the degree of coarseness varies, and a proportion of fines is advantageous.

Another producer has superposed a tall distillation shaft and is capable of dealing with wood waste above 20 mm. size if containing not more than 25% of water.—H. J. H.

Petrol; Blended —— containing casinghead gasoline. F. Bordas. Ann. Falsif., 1920, 13, 539—543.

In view of recent importations into France of blended gasoline, investigations have been instituted by the Ministry of Finance to differentiate between these spirits and straight run petrol, in view of the increased fire risks and the marked heavy residue. Modifications of the current tests are described.—A. E. D.

Mineral oils; Estimation of pitchy substances (asphalt and resin) in ——. G. Armani and A. G. Rodano. Giorn. Chim. Ind. Applic., 1920, 1, 45—48.

The usual method of determining asphaltic and pitchy substances in mineral oil by shaking a light petroleum solution of the oil with concentrated sulphuric acid, allowing to settle, measuring the volume of the dark lower layer and subtracting therefrom the volume of the sulphuric acid used (*cf.* Villavecchia, "Applied Analytical Chemistry," Vol. I., p. 339), occasionally fails, the volume of the pitchy matter being very high and sometimes exceeding that of the oil employed. In such cases the following method may be employed: A weighed quantity of the oil (about 10 c.c.) is dissolved in a separating funnel, in 100 c.c. of light petroleum (sp. gr. not above 0·700), which should not be attacked by concentrated sulphuric acid; 5 c.c. of concentrated sulphuric acid (66° B., sp. gr. 1·84) is added and the funnel stoppered and shaken energetically for some minutes and then left at rest for at least 12 hrs. When the two layers have separated, 50 c.c. of the clear petroleum layer is pipetted off, washed with water in another separating funnel until neutral and placed in a tared flask. The light petroleum is then distilled off, and the residue dried at 100° C. and weighed. Multiplication of this weight by 2 gives the amount of pure mineral oil in the amount used. With oils containing normal proportions of pitchy substances the results obtained by this new method agree with those given by the old method, but when the latter yields a volume of pitchy matter equalling or surpassing that of the oil itself the authors' procedure yields much lower results. The new method is applicable to mineral lubricating oils and also to the distillation residues of mineral oils. With mineral oils containing fatty substances or blown vegetable oils it is necessary first to remove the fatty substances by saponification.—T. H. P.

Lubricating oils; Methods of examination of ——. G. F. Robertshaw. J. Inst. Petrol. Techn., 1920, 6, 324—364.

Physical and chemical properties of lubricating oils are discussed in some detail, and published methods of testing them are described briefly. A bibliography is appended.—A. E. D.

Lubricating oils in internal combustion engines; Carbonisation of ——. F. H. Garner. Inst. Petrol. Techn., 18.1.21. [Advance proof.]

Asphaltic resins in lubricating oils may be estimated by means of the adsorptive power exhibited by animal charcoal. A known mass of the oil (20 g.) mixed with 100 g. of charcoal is extracted in a Soxhlet apparatus with petroleum ether for 2 hrs., and the recovered oil is weighed. In similar oils the resin content influences both the extent of carbonisation and the Conradson coke value (J., 1912, 912; Amer. Soc. Testing Materials Standards, 1918, 620). Oils of similar distillation range from Texas and Pennsylvania crude oils show similar evaporation losses at the same temperature of evaporation, and there seems to be a direct relation between the evaporation loss and fire test. As a criterion of the behaviour of an oil in the engine, with regard to formation of carbon deposits, the Conradson coke value is superior to the carbonisation value, *i.e.*, the percentage of asphaltenes formed on heating for a definite period at a fixed temperature. The subjoined table gives some characteristic results:—

Oil.	Heated for 4 hrs. at	Resin content.	% asphaltenes formed.	Conradson coke value.
Light distillate ..	200° C.	1·2	1·36	0·19
„ „ (refined)	200° C.	0·6	0·50	—
Heavy distillate ..	200° C.	2·4	0·60	0·075
„ „ (refined)	200° C.	1·2	0·40	—
Cylinder stock ..	300° C.	5·11	2·27	2·6

A very full bibliography appertaining to the various tests for lubricating oils is given.—A. E. D.

Montan wax from lignite; Extraction of ——. E. Donath. Brennstoff-Chem., 1920, 1, 86—87; 1921, 2, 28.

Acetone is suggested as a substitute for the benzol-alcohol mixture used for extracting montan wax from lignite (*cf.* G.P. 325,165; J., 1920, 814 A). The purpose of the alcohol is to take up moisture which might hinder the action of the solvent. Acetone however is also miscible with water, and moreover appears to equal benzol as an extractive agent when applied to Bohemian lignites.—H. J. H.

Soot etc. in boiler plants. Donath. *See* I.

Oxidation of lignite products. Schneider. *See* III.

Emulsions. Bechhold and others. *See* XII.

Patents.

Coal washers. Bureau d'Etudes Ind. F. Courtoy et L. Dubois, and F. Courtoy. E.P. 156,833, 12.6.19.

In a coal washer of the type comprising a trough having one compartment for receiving the coal and another for containing reciprocating pistons for producing suction, the residuary products are removed by suction through valves which are operated directly by the pressure of the washing water and which regulate the suction automatically according to the charge of coal and the proportion of waste required to be removed.—W. E. F. P.

Coal briquettes; Production of ——. W. Broadbridge, E. Edser, W. W. Stenning, and Minerals Separation, Ltd. E.P. 155,875, 26.8.19.

An aqueous suspension of coal obtained from colliery waste by the froth flotation process (E.P. 7803 of 1905, F.P. 354,960; J., 1905, 1177) is agitated with liquefied binding medium, *e.g.*, melted pitch, with which the particles become coated so that they may be briquetted. Cresol or kerosene oil may be added to promote frothing and slaked lime to assist flocculation, and the concentration and addition of the binding agent may be carried out in one operation. The crushing of the pitch being unnecessary, soft pitch may be used.—C. I.

Fuel briquettes from coke waste, coal waste, brown coal, or the like; Manufacture of ——. R. Matsunaga and S. Aoki. E.P. 157,007, 8.3.20.

A mixture of the washed and powdered waste (not more than 2 pts.) with powdered coking bituminous coal (1 pt.) is moistened with water and pressed in moulds, and the briquettes are roasted in an oven. The materials are previously ground to pass a sieve of about 22 meshes to the inch.—W. E. F. P.

Peat; Treatment of ——. D. B. MacDonald, and The Densified Peat, Fuel and Products, Ltd. E.P. 155,895, 20.9.19.

Wet peat is pulped and compressed by forcing it through a reduced aperture. The product is cut into blocks and dried by rapid heating and cooling. It may be used as fuel or as a substitute for wood. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 1216 of 1873, 3536 of 1877, 6704 of 1887, 25,627 of 1897, 2859 of 1901 and 6153 of 1902; J., 1888, 381; 1899, 255; 1903, 485.)—C. I.

Fuel residues; Process of separating slags containing iron from coke and other——. F. Krupp A.-G. Grusonwerk. E.P. 150,333, 21.8.20. Conv., 26.8.19.

Fuel residues after crushing are passed through highly concentrated magnetic fields, obtained, for example, by means of the separator described in E.P. 100,063 (J., 1916, 694), whereby the slag which almost always contains iron is separated from the unburnt coal and coke. Owing to the complete separation obtained the slag is well suited for the manufacture of building stones.—C. I.

Coking ovens; Horizontal ——. *Coke ovens.* Soc. Franco-Belge de Fours à Coke. E.P. (A) 125,590, 29.5.19 (Conv., 29.5.18). and (B) 156,034, 12.4.20.

(A) The following arrangement makes it possible to use both rich and poor gas at the same time in regenerative horizontal coke ovens with vertical heating flues. Two pairs of independent regenerators are provided on either side of the longitudinal centre line of the battery, the inner one of each pair communicating with the odd numbered half-sole flues, the outer one divided into compartments each of which communicates with one of the even-numbered half-sole flues. When heating with coke-oven gas air is admitted to both chimney flues on one side of the battery, is preheated in the regenerators, and the products of combustion pass through the regenerators on the other side. When heating with producer gas the outer regenerator on one side is cut off from the chimney flue and the gas is admitted, while air is admitted to the interior regenerator, and the gas and air pass up alternate flues to unite and burn in the vertical heating flues. As the outer regenerators are divided into compartments, part of the battery may be operated in each way. The cross-sections of the connexions from the chimney flues to the regenerators are proportioned to the distance from the chimney. (B) In coke ovens of the type described under (A) difficulty is met with in forming a hard coke from certain coals owing to the top of the charge not being coked quickly enough. To obviate this the vertical heating flues are arranged in pairs, the air passing up one flue and the products of combustion down the other; this flow is periodically reversed, while the gas is admitted continuously in the upper part between the two flues. The temperature is further controlled by air ports in the pier. Beneath the ovens are two continuous flues, each connected with one regenerator and with alternate heating flues. —C. I.

Coke oven; Regenerative ——. Koksofenbau u. Gasverwertung A.-G. G.P. 327,002, 18.4.16.

In an oven for alternative heating with rich or poor gas, in which the air inlets to two neighbouring heating flues are adjacent to each other and are separated by thick walls from the similarly arranged gas inlets, an equalising flue in the upper part of the regenerator is connected with the air chamber; the air connexions to the heating flues branch off from this equalising flue. These can therefore be so arranged that two air inlets and two gas inlets always lie directly next each other. The air and producer-gas inlets are always parted by the thick walls so that leakage from one to the other and the production of an explosive mixture is prevented.—C. I.

Retort-furnace for use in making gas [from vegetable matter]. B. R. Pfeifer. E.P. 156,029, 20.3.20.

A rectangular retort set upon a furnace is traversed horizontally by flues carrying the gases of combustion from the fire. The retort is charged with straw or the like through an end door, and the gas passes out through an exit pipe, the tar etc. being removed through the charging door at the end of an operation.—C. I.

Retort [for making gas from straw]. G. Harrison and E. G. S. Bennett. U.S.P. 1,363,588, 28.12.20. Appl., 27.3.19.

For the production of gas from straw a cylindrical retort is used with a conduit running through it. An intensifier is placed in the conduit, consisting of a pair of spaced perforated walls containing a non-combustible and heat-retaining filling material. —J. H. J.

Gas manufacture. G. Helps. E.P. 156,812, 17.5.17.

A gas generator with superheater is combined with a vertical retort placed above it. The air blast in the generator passes through the superheater and heats a steam boiler. The steam blast passes in the reverse direction through the superheater, yields superheated water-gas in the generator and heats the retort. The coke required for the generator is fed in directly from the retort. The heat of the latter may be augmented if necessary by burning part of the water-gas.—C. I.

Coal or fuel carbonisation and gas-making plant; Combined ——. R. and J. Dempster, Ltd., H. S. Knight, and F. J. Siddall. E.P. 157,036, 2.7.20.

A producer- or water-gas generator is connected with a chamber in which one or more retorts are set, the gas space being filled with checker-work. The generator-gas is at first burnt in this space to effect the distillation of a fuel charge in the retorts, whilst at a later stage the water-gas from the producer after passing around the retorts is led into the latter.—C. I.

Illuminating gas; Process of obtaining —— *from lignite.* E.P. Schoch. U.S.P. 1,364,455, 4.1.21. Appl., 30.8.19.

Lignite is distilled until the percentage of carbon dioxide in the gas evolved shows a marked decrease, all the gas is collected, and the carbon dioxide removed.—C. I.

Gas producer and superheater; Combined ——. G. F. Rendall, Assr. to Carbon Products Co. U.S.P. 1,366,213, 18.1.21. Appl., 29.6.17.

The superheater is inside the combustion chamber of the producer and discharges its steam into a chamber below the grate, whence it passes up through the producer. A part of it is used to inject preheated air into the producer from a condenser on the gas main.—C. I.

[Gas] retort; Continuous vertical —— *with preheater.* K. Barthel. G.P. 323,837, 26.9.18.

The heat exchanger or preheater consists of a cylindrical vessel placed above the retort with a hopper interposed and containing a gas-collecting funnel, the mouth of which is of greater cross-section than the retort.—C. I.

Gas washer and purifier. G. Coune. E.P. 155,859, 30.4.19.

A gas washer consists of a fixed horizontal cylin-

der partly filled with liquid and divided into compartments in each of which rotates a washing wheel. Each wheel has a hollow hub conveying the gas, and consists of a double set of rotating elements divided by a disc which also divides the hub. The gas passes first outwards from the axis and then inwards in each compartment.—C. I.

Gas-epurator [purifier]. V. L. Cazes. U.S.P. 1,364,832, 4.1.21. Appl., 14.11.18.

A HORIZONTAL scrubber has upright baffles attached alternately to the top and bottom. The bottom of the scrubber is perforated and below it is an ash-pit fitted with removable scrapers.—C. I.

Gas washing and humidifying process. J. P. Ruth, jun. U.S.P. 1,365,278, 11.1.21. Appl., 16.8.17.

LIQUID is forced up a cylindrical vessel by centrifugal force or otherwise and the gas is drawn in at a separate inlet in the lower part of the vessel by the partial vacuum produced by the movement of the liquid. The liquid flows over a baffle, passes downward, and is returned to the washing vessel. —C. I.

Motor fuels. E. W. Stevens. E.P. 135,514, 21.11.19. Conv., 21.11.17.

A MOTOR fuel contains 50—55 pts. of kerosene or a similar oil, 25 pts. of ethyl alcohol, 5 pts. of fusel oil, 10 pts. of sulphuric or petroleum ether or casinghead gasoline, and 8 pts. of toluol or xylol. In aeroplane fuel the proportion of kerosene is reduced to about 40% of the mixture.—L. A. C.

Liquid fuel; Burners for ——. E. F. Hooper and J. E. Weyman. E.P. 156,428, 13.2.20.

A SPRAY nozzle for liquid fuel (tar or heavy oil) is controlled by a needle valve operated by a micrometer screw for fine adjustment. The valve may be freely moved on disconnecting the screw. The oil is projected into a mouthpiece of refractory material which has its smallest diameter near the inlet and then diverges outwards. Air is admitted around the edge of a disc which is movable axially away from the inlet of the mouthpiece to vary the opening. The inner surface of the mouthpiece is provided with helical ribs.—W. F. F.

Oil-shale-treating retort; Vertical ——. J. H. Galloupe, Assr. to The Galloupe Shale Process Co. U.S.P. 1,365,822, 18.1.21. Appl., 18.8.19.

OIL shale is fed into the annular space between two vertical cylinders situated within a cylindrical casing. Flues convey the hot gases from a furnace through the inner cylinder, which is rotated, and also through the space between the middle cylinder and the outer casing.—L. A. C.

Oils; Process of purifying ——. D. T. Day. U.S.P. 1,365,894, 18.1.21. Appl., 18.2.18.

THE oil is brought into contact with cuprous chloride.—L. A. C.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Charcoal burning; Relation of composition of gases evolved in —— to the yield of charcoal. P. Klason. Brennstoff-Chem., 1920, 1, 79—80.

CHARCOAL burning in heaps is assumed to be equivalent to distillation in a retort at 500° which yields a product of composition equivalent to $C_{16}H_4O$, whereas distillation in a retort at 400° gives a "retort charcoal" which may be represented as C_7H_4O. Pine wood gives a yield of 37% of charcoal by distillation at 400° C., and 31% at 500° C. The yield is further lowered when charcoal is burnt in the heap by partial combustion. In an actual test the yield was 27%. The gas from charcoal burning in heaps is regarded as a mixture of the gases from the distillation of wood up to 500° C., the CO_2 content of which is 38%, and the products of combustion of $C_{16}H_4O$, which contain 20% CO_2. On this basis the composition of the gases from pine wood was calculated as CO_2 25·8% (25·6), CO 9·3% (9·8), (CH_4+H_2) 10·7% (9·7), N_2 54·7% (54·9). The figures in brackets were those actually determined. It follows therefore that the CO_2 content of the gases will be high when products of combustion are absent, thus indicating a high yield of charcoal. Actually the percentage of CO_2 in the gases is roughly a measure of the yield of charcoal by weight and therefore a useful method of control of the charcoal-burning process.—H. J. H.

Softening of carbon. Gmachl-Pammer. *See* VII.

Distillation of exhausted beet slices. Paar and Starke. *See* XVII.

PATENTS.

Shaft furnace for distillation or carbonisation of waste material, refuse heaps, bituminous shales, and the like [lignite and non-caking coals]. H. Koppers. G.P. 322,547, 29.10.16.

IN a furnace (of the Rolle type) in which the material is made to descend in a layer in contact with the heated iron walls, by means of an inlet perforated for the escape of the gases and vapours produced, the iron heating mantle of the furnace is rotatable in order to prevent local overheating. Ribs on the outer surface of the iron mantle project into grooves in the surrounding masonry, forming a series of heating flues around the iron mantle.—J. H. L.

Finely divided fuel; Distillation of ——. Bünzlauer Werke Lengersdorff und Co. G.P. 326,604, 2.2.18.

To effect the distillation of a close-lying fuel, *e.g.*, coal dust, by means of a heated gaseous medium, the generator is arranged in two parts. In the upper part, which can be rotated, a counter current of hot gas acts on the fuel, which reaches the lower part as coke. From the latter gas is generated and serves to effect the distillation of more fuel.—C. I.

Gas-fire radiants; Manufacture of ——. South Metropolitan Gas Co., and H. Hollings. E.P. 156,416, 21.1.20.

IN the manufacture of gas-fire radiants discoloration of the radiants due to overheating is avoided by substituting for the asbestos usually incorporated a vegetable or animal fibre such as hair, flax, hemp, cotton, or jute. If necessary the vegetable or

animal fibre is subjected to a preliminary washing with dilute hydrochloric acid to remove iron impurities.—J. S. G. T.

Gas-filled glow discharge lamps; Electric ——. A Lederer. E.P. (A) 17,036, 17.7.14, and (B) 17,646, 25.7.14. Conv., (A) 19.7 and (B) 25.7.13.

(A) The electrodes of a gas-filled glow discharge lamp are composed of a solid metal other than the alkali metals, *e.g.*, aluminium, magnesium, tungsten, and a small quantity of one or more of the alkali metals is introduced into the lamp, preferably in the form of a deposit which is not vaporised during operation of the lamp. (B) In a gas-filled lamp as described under (A) the small quantity of alkali metal introduced is confined to the region of the anode or of both electrodes.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Tar; Estimation of water in ——. Mitteilung des Gasinstituts (Lehr- und Versuchsanstalt). Gas- und Wasserfach, 1921, **64**, 71—73.

Owing to the great variations in the percentage of water in tar as it passes through the different receivers in the tar works, samples for estimating the water in tar deliveries should be taken either as the tar flows into the wagons, or from the wagons themselves. In the former case a narrow, valved branch pipe, which should be vertical or sharply inclined, is attached to the delivery pipe some distance from the end, and discharges a continuous sample into a receiver: in the latter a number of samples are withdrawn from the wagons by means of an iron tube, 3—5 cm. diam., fitted with a stopper or valve at the bottom which can be opened and closed by means of an iron rod passing down the tube. Sampling should be done soon after filling the wagon, and the total sample taken by either method must be well agitated before weighing a portion for estimating the water. Three methods are available for the water estimation: fractional distillation, vacuum distillation, and Beck's method (J., 1909, 1027). Distillation methods have the advantage that water, naphthalene wash-oil, and benzol wash-oil are estimated in one operation. The tar is distilled in a copper flask fitted with a Liebig condenser until the oily distillate is free from water, *i.e.*, about 200° C., and the volume of water is read off direct in a measuring cylinder. The addition of 10% of xylol and some pumice stone to the tar facilitates the distillation and prevents bumping. Decomposition of the tar is reduced if the distillation is carried out under vacuum, but frothing of the contents of the flask renders this method somewhat difficult to operate. The tar is first heated until it begins to boil under ordinary pressure, and the distillation is then carried out without further heating by gradually raising the vacuum to about 700 mm. Beck's method is more rapid in operation than the other methods and gives results in very close agreement with those obtained by fractional distillation.—L. A. C.

Tar; Technical chemical analysis of ——. P. Falciola. Giorn. Chim. Ind. Applic., 1920, **1**, 38—45. (*Cf.* J., 1917, 638.)

For sampling tar a dipping cylinder similar to that employed for crude glycerin (J., 1911, 556) may be used. In determining the moisture content of tar by distillation, bumping and excessive frothing may be avoided by heating 80—100 g. of the tar in a 700—800 c.c. glass flask fitted at the neck with two large glass bulbs containing a thermometer. An annular burner is used and is placed first on a level with the surface of the tar, using small flames; it is then gradually lowered and the flames increased until these reach the bottom of the flask. Sulphur in tar may be estimated as follows: About 0·5 g. of the tar is intimately mixed by means of two spatulas with about 15 g. of a mixture of 4 pts. of potassium chlorate, 1 pt. of potassium nitrate, and 1 pt. of ammonium nitrate. The mixture is introduced into a test-tube and this supported vertically in a very tall beaker by means of glass beads or the like. This beaker is placed in a still wider and taller one, a fuse in contact with the mixture being ignited. The test-tube and its containing cylinder are then covered with a tall heavy glass cylinder with its edge notched with file marks, while about 500—600 c.c. of water containing sodium hydroxide and a few drops of bromine water is placed in the beaker. The combustion of the mixture proceeds gradually and lasts several minutes, the gases emitted being washed by the alkaline liquid sealing the cylinder. When the apparatus has cooled the cylinder is removed and washed, the washings, as well as those of the test-tube and beads, being added to the liquid decanted from the beaker. The whole liquid is then acidified with hydrochloric acid, concentrated, filtered, and precipitated hot with barium chloride. The small amount of carbonaceous residue sometimes left on the filter does not invalidate the results. For tars, bitumens, and petroleums this method gives results slightly lower than those obtained by the Carius method.
—T. H. P.

Lignite products; Action of oxgen under pressure on ——. W. Schneider. Brennstoff-Chem., 1920, **1**, 70—72, 80—85.

Molecular oxygen, especially in the form of air, has certain advantages, both financial and technical, over oxidising agents in common use. The velocity of reaction can be varied within wide limits by changes of pressure and temperature. Tubular autoclaves have been constructed and used for effecting oxidation under a pressure of 70 atm. and at 200° C. The contents could be sampled so as to permit the study of the course of the reaction. In such apparatus it was attempted to prepare fatty acids and soaps from the products obtained from lignite. The humic portions, though quantitatively most important, are unsuitable as starting material owing to their cyclic structure. The bitumen compounds, containing long aliphatic chains and therefore presumably a more promising raw material, were not so satisfactory in practice as the tar oils. Viscous acid substances, amounting to 55% of the oil taken, were obtained by oxidising lignite tar oil in presence of alkalis and acidifying the product. These acids were presumably polynaphthenic acids. Commercial paraffins containing compounds with about 25 carbon atoms were oxidised and yielded mainly monobasic acids with about 13—19 carbon atoms and small quantities of dibasic acids and other compounds, *e.g.*, alcohols and aldehydes, presumably intermediate compounds. The influence of conditions on oxidation—*e.g.*, temperature, pressure, concentration, catalysts, and time—was studied in the experiments on paraffins, and the behaviour of paraffin when heated in presence of alkali at 170° C. and 30 atm. pressure was taken as a standard of comparison. The salts of the fatty acids obtained seemed to serve as satisfactory soaps. Montan wax, though oxidised by ozone at air temperature, proved more refractory towards compressed oxygen than paraffins. Fatty acids were formed, but presumably so slowly that they were extensively broken down to small molecules, so that no large yields of soap-forming products were obtained.—H. J. H.

Benzene and benzaldehyde; Mode of pyrogenic decomposition, at high temperature, of ——. E. Peytral. Bull. Soc. Chim., 1921, **29**, 44—47.

In the pyrogenic decomposition of benzene at high temperatures the principal change is the formation

of diphenyl and hydrogen. At the same time some methane is formed by more profound decomposition either of the benzene or of the diphenyl. In the decomposition of benzaldehyde there are two primary changes, namely, $C_6H_5.CHO=C_6H_6+CO$ and $2C_6H_5.CHO=C_6H_5.C_6H_5+2CO+H_2$. At the same time a small amount of the benzaldehyde is reduced by the hydrogen giving anthracene, and some of the diphenyl is decomposed giving methane. —W. G.

Δ^1-Dihydronaphthalene. III. Modes of formation of Δ^1-dihydronaphthalene. F. Straus and L. Lemmel. Ber., 1921, 54, 25—40.

THE amounts of Δ^1- and Δ^2-dihydronaphthalenes in mixtures of these substances with naphthalene and tetrahydronaphthalene can be estimated by means of mercuric acetate which oxidises the first-named with production of mercurous acetate in accordance with the scheme: $C_{10}H_{10}+2(CH_3.CO_2)_2Hg+2H_2O=C_{10}H_{10}(OH)_2+2CH_3.CO_2Hg+2CH_3.CO_2H$, forms an additive compound with the Δ^2-derivative which is soluble in benzene, and does not react with naphthalene or its tetrahydro compound. Isomerisation of the Δ^2- to the Δ^1-isomeride under the influence of alcoholic sodium ethoxide solution occurs with greater readiness than was previously supposed. In the preparation of Δ^2-dihydronaphthalene by the action of sodium and ethyl alcohol on naphthalene there is a partial isomeration of the Δ^2- into the Δ^1-derivative, which is thus always present to the extent of about 5%, and if, after solution of the sodium is complete, the final concentration of the alkoxide is raised by distilling off a portion of the alcohol, the isomerisation may be made to occur quantitatively, thus giving the simplest method of preparing Δ^1-dihydronaphthalene, which can be separated from admixed naphthalene and tetrahydronaphthalene by conversion into the dibromide from which the hydrocarbon is readily regenerated. The dihydronaphthalene obtained from *ac*-tetrahydro-β-naphthol, β-chlorotetrahydronaphthalene, and *ac*-tetrahydro-β-naphthylamine nitrite, is the Δ^1-compound and not the Δ^2-derivative as supposed previously. The dihydronaphthalenes are conveniently reduced to tetrahydronaphthalene by hydrogen in alcoholic solution in the presence of palladium; under these conditions, the second nucleus remains unattacked. (*Cf.* J.C.S., Mar.)—H. W.

Emulsions. Bechhold and others. See XII.

PATENTS.

Anthracene; Process for the purification of crude ——. Kinzlberger und Co. E.P. 144,656, 8.6.20. Conv., 31.3.17. Addn. to 144,648.

IN the process described in the chief patent (J., 1921, 5 A), the use of a large excess of potassium hydroxide avoids the necessity of removing excess of water by distillation and enables the quantitative formation of potassium-carbazole to take place at a lower temperature, *e.g.*, 120° C.—L. A. C.

Fusions with molten caustic soda or caustic potash; Method of conducting ——. B. D. Steele and R. B. Robertson. E.P. 156,269, 9.2.18.

A HOT concentrated solution of a sulphonate, *e.g.*, sodium benzenesulphonate, is fed slowly on to the surface of molten sodium or potassium hydroxide. —L. A. C.

Bituminous material; Composition of matter containing ——. J. M. Weiss, Assr. to The Barrett Co. U.S.P. 1,340,855, 18.5.20. Appl., 8.11.19.

A COMPOSITION suitable as a fuel for Diesel engines, for treating the surfaces of roads, and as a paint or the like, is composed of about 80 pts. of pitch, 20 pts. of petroleum naphtha, and 1—3 pts. of tar acids. The addition of the tar acids causes the mixture to form a colloidal solution or suspension showing practically no tendency to separate.

Fumes; Removing —— *from [bituminous] materials.* K. B. Howell, Assr. to The Barrett Co. U.S.P. 1,348,140, 27.7.20. Appl., 23.12.18.

A COOLING medium is passed over hot bituminous material, *e.g.*, pitch, which is being comminuted to convert it into filamentary form. Substances that are volatile at the temperature of operation are carried away by the cooling medium which circulates in a closed circuit including a condenser.

Cresols; Separation of meta- and para- ——. C. R. Downs and R. S. Potter, Assrs. to The Barrett Co. U.S.P. 1,364,547, 4.1.21. Appl., 10.4.19.

A MIXTURE containing *m*-cresolsulphonic acid and *p*-cresol is distilled *in vacuo* in the presence of steam at such a temperature that *p*-cresol distils, but the *m*-cresolsulphonic acid is not appreciably decomposed.—L. A. C.

Benzanthrone; Method of purifying ——. L. C. Daniels, Assr. to National Aniline and Chemical Co. U.S.P. 1,365,024, 11.1.21. Appl., 9.1.20.

BENZANTHRONE is dissolved in hot halogen derivatives of aromatic hydrocarbons, insoluble impurities are separated, and the solution is cooled, whereby benzanthrone is deposited from solution. —L. A. C.

Phenols from red-wood [tar]; Production of ——. W. J. Hund. U.S.P. 1,365,407, 11.1.21. Appl., 25.4.17.

THE tar obtained by distilling resinous red-wood above 450° C. is distilled, and the oily fraction collecting between 150° and 250° C. is extracted with an alkali hydroxide solution to dissolve phenolic compounds which are afterwards separated from the solution.—L. A. C.

Aromatic hydrocarbons; Process of producing ——. A. S. Ramage, Assr. to Bostaph Engineering Corp. U.S.P. 1,365,849, 18.1.21. Appl., 24.6.18.

AN alkyl group in an aromatic compound containing one or more alkyl groups is replaced by hydrogen by treating the aromatic compound with hydrogen at 700° C in the presence of a lower oxide of iron as catalyst.—L. A. C.

Lubricants, resins, etc.; Manufacture of hydrocarbons serving as ——. Badische Anilin- u. Soda-Fabr. G.P. 326,729, 9.6.18.

BY the interaction of xylol and ethylene chloride in the presence of aluminium chloride, products free from chlorine are obtained either as a viscous liquid mixture of high flash point or a solid resin. —C. I.

Washing oils etc.; Continuous process and apparatus for distillation of light products from ——. C. H. Borrmann. G.P. 326,730, 25.11.17.

THE preheated oil is directly heated in a system of pipes under atmospheric pressure, to a temperature above the highest boiling point of the light products desired, so that a quantity of heavy oil also comes over. The vapour produced serves for driving off the main part of the light oil in a continuous still, the crude light oil being freed from the higher boiling fractions in a directly connected fractionating column. By a variation the process can be used for the separation of the tarry residue from washing oil.—C. I.

Heater for obtaining hot air with reduced oxygen content. U.S.P. 1,352,481. *See* I.

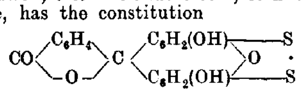
IV.—COLOURING MATTERS AND DYES.

Thiofluorescein; Constitution of —— and its technical applications. T. Maki. J. Coll. Eng., Tokyo, 1920, **11**, 1—38.

Thiofluorescein, obtained by Wyler (Diss., Zürich, 1894), and studied later by Meyer and Szanecki (J., 1900, 1007), is obtained in a yield of 94% by adding a solution of 63 g. of sodium hydroxide, 34 g. of sulphur, and 70 c.c. of water to 50 g. of fluorescein, 12 g. of sodium hydroxide, and 30 c.c. of water, and heating the mixture with constant agitation to 115° C. in ½ hr., to 130° during the next 2 hrs., adding 50 c.c. of water, and heating for a further 2 hrs. The presence of water is essential, as sulphurisation at these temperatures does not take place in its absence. Thiofluorescein is formed slowly and incompletely by the action of sodium polysulphide, more readily by sodium sulphide, and with ease in the presence of free alkali. The alkali opens the pyrone ring, producing a compound which is sulphurised with ease, whereas fluorescein is sulphurised only with difficulty. The reaction is complete when a diluted sample shows no fluorescence. The product is dissolved in water, acidified, and filtered. The major portion of the admixed sulphur is deposited when a solution of the neutral ammonium salt is allowed to stand overnight. The product obtained by acidifying the filtrate is sufficiently pure for dyeing, but requires further purification prior to analysis. The composition of the purified product is $C_{20}H_8O_3S_2(OH)_2$, and its constitution and that of its reduction product, thiogallein, have been elucidated by a study of its behaviour on reduction, oxidation, bromination, nitration, etc. Thiofluorescein, or fluorescein disulphide, has the constitution



and thiogallein is the corresponding dimercaptan of fluorescein. The former is an orange-brown acid dye, much faster than fluorescein, whilst the latter is a powerful mordant dye which is dyed from a neutral or acid bath in presence of hydrosulphite to prevent oxidation during dyeing. The shades of thiogallein are closely related to, but much deeper and faster than, those of gallein; thus the former produces a dark red-brown on alumina, blue-black to black on chromium, brown-black to black on iron, and violet on tin, increased in depth and fastness by subsequent treatment with copper. (*Cf.* J. C. S., March.)—F. M. R.

Fuchsones and [triphenylmethane] dyestuffs derived therefrom. P. Demont. Rev. Gén. Mat. Col., 1920, **24**, 65—87.

By condensing 1 mol. of benzaldehyde-*o*-sulphonic acid with 2 mols. of *o*-cresol in the presence of 70% sulphuric acid, a triphenylmethane compound having the formula,

$$[C_6H_3(OH)(CH_3)]_2.CH.C_6H_4.SO_3H,$$

is obtained. This, on nitration with 20% sulphuric acid and potassium nitrate, yields a dinitro-derivative,

$$[C_6H_4(SO_3H)][C_6H_2(CH_3)(OH)(NO_2)]C:C_6H_2(CH_3)(NO_2):O,$$

and a mono-nitro compound having the formula,

$$[C_6H_4(SO_3H)][C_6H_4(OH)]C:C_6H_2(OCH_3)(NO_2):O \text{ or}$$
$$[C_6H_4(SO_3H)][C_6H_2(CH_3)(OH)NO_2)]C:C_6H_3(CH_3):O.$$

Both substances dye chromed wool from an acid bath in yellowish-brown shades which are not fast to light or milling.—A. J. H.

Action of dyes on yeast. Fraser. *See* XIXb.

Vegetable fibres; Treatment of ——. Gillet et Fils. E.P. 150,665, 12.12.19. Conv., 2.9.19.

Vegetable fibres are made to resemble wool both in physical properties, such as feel and appearance, and in chemical qualities, such as behaviour towards dyes, by impregnating them with the products of hydrolysis of various proteins, such as casein, albumin, and gelatin, by mineral acids. Hydrolysis of the protein may be effected either before treatment of the fibre or on the fibre; in either case the fibre is afterwards washed with water, dilute acid, dilute alkali, or a solution of a salt, such as sodium bisulphate, ammonium sulphate, or sodium phosphate, and may be subsequently treated with formaldehyde or other protein precipitant.—B. V. S.

Impermeable and non-hygroscopic insulating material. M. Arosio. E.P. 131,907, 28.8.19. Conv., 26.6.18.

Vulcanised fibre is provided with an adherent coating of celluloid or cellulose acetate (*cf.* E.P. 131,911; *infra*).—B. V. S.

Hygroscopic materials; Process for coating —— with a film of impermeable non-hygroscopic material adhering thereto, and the product of said process. M. Arosio. E.P. 131,911, 28.8.19. Conv., 26.6.18.

In providing hygroscopic material, such as wood, vulcanised fibre, or paper, with an adherent impermeable coating of a substance such as celluloid or cellulose acetate, the material is first thoroughly dried and then saturated with the solvent subsequently to be used for the coating substance. It is then steeped for a short time in a weak solution of the coating substance, containing also a suitable proportion of mineral colouring matter, withdrawn, and allowed to dry. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 267 of 1884, 12,693 of 1896, 7134 of 1903, 18,503 of 1909, 16,810 of 1911, and 110,650; J., 1897, 620; 1904, 376; 1912, 82; 1917, 1232.)—B. V. S.

Casings or envelopes for glass containers, such as large bottles (demijohns) and the like; Protecting ——. M. Arosio. E.P. 131,918, 28.8.19. Conv., 29.8.18.

A protecting casing is made of wood, covered all over, or where necessary, with vulcanised fibre, which is then rendered impermeable and non-hygroscopic by the process described in E.P. 131,911 (*cf. supra*).—B. V. S.

Fabrics, especially paper-yarn fabrics; Impregnation of ——. O. Ruff. G.P. 327,399, 27.10.17.

FABRIC impregnated with a phenol, such as cresol, formaldehyde, and an alkali, is heated in an atmosphere containing carbon dioxide. The change of the caustic alkali to carbonate is favourable to the formation of the water-insoluble phenol-formaldehyde condensation product, and both the dry and wet strengths of the fabric are increased.—A. J. H.

Cellulose acetate; Manufacture of solutions of ——. Badische Anilin- und Soda-Fabrik. E.P. 145,511, 22.6.20. Conv., 9.2.14.

CELLULOSE acetate soluble in acetone is dissolved in a fully hydrogenised monocyclic ketone with or without the addition of suitable diluents. For example, 4 pts. of cellulose acetate is dissolved in 96 pts. of cyclohexanone to give a solution suitable for lacquering and drawing to artificial silk.
—A. J. H.

Plastic [nitrocellulose composition]. L. E. Barton and H. A. Gardner, Assrs. to Titanium Pigment Co. U.S.P. 1,365,882, 18.1.21. Appl., 7.2.17.

THE composition contains nitrocellulose, titanium oxide, and camphor.—A. J. H.

Larch; Recovery of organic products from ——. H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,364,418, 4.1.21. Appl., 14.5.18. (*Cf.* U.S.P. 1,358,129; J., 1921, 6A.)

WOOD of the western larch is comminuted and digested with sulphite liquor to recover sulphite pulp and a waste liquor containing soluble constituents of the larch, including conversion products of galactan.—J. H. L.

Cellulose; Process for separating —— from wood and other materials containing cellulose. R. Hartmuth. G.P. 326,705, 9.7.19.

THE raw material is heated with phenols, or substances having a phenolic character, in a concentrated form or diluted with water, alcohol, benzene, benzene derivatives, or aliphatic hydrocarbons, in the presence of a catalyst. A suitable catalyst is 0·01% of hydrochloric acid. The lignin combines with the phenol to form a soluble substance which may be used as an adhesive, lacquer, or the like, while the cellulose remains white and unchanged.
—A. J. H.

Cellulose; Process for obtaining —— from wood and similar materials containing cellulose. W. Schlosser. G.P. 328,729, 27.9.19.

THE raw material is treated either hot or cold with primary and secondary aliphatic and aromatic amines, either alone or diluted with alcohol or benzene etc. The reaction proceeds more rapidly in the presence of a condensing agent such as hydrochloric acid or zinc chloride.—A. J. H.

Cellulosic materials; Process for the disintegration of ——. R. Schwarzkopf. G.P. 328,730, 27.9.19.

THE raw material is treated either hot or cold with acid chlorides, such as sulphuryl chloride, thionyl chloride, phosphorus oxychloride, acetyl chloride, benzoyl chloride, etc., which may be diluted with indifferent solvents, such as benzene and carbon tetrachloride. In cases where the acid chlorides do not dissolve the non-cellulosic substances directly the cellulose may be purified by an after-treatment with alkalis.—A. J. H.

Parchment paper; Manufacture of ——. C. G. Schwalbe. G.P. 303,305, 23.6.17.

BEFORE being made into paper the raw material, such as cellulose, half-stuff, mechanical wood pulp, etc., is treated in the edge runner or in the hollander with oxidising agents, such as oxides of nitrogen, permanganates, peroxides, perchlorates, or perborates. By this means parchmentisation is effected and a product of increased tenacity is obtained.—A. J. H.

Cigarette-paper; Manufacture of ——. Zellstofffabr. Waldhof. G.P. 327,735, 29.11.17.

SULPHITE pulp to be used for the manufacture of cigarette-paper is treated with alkalis whereby its unpleasant taste is removed.—A. J. H.

Fermentable matter; Apparatus for recovering volatile and —— from liquids [sulphite-cellulose waste lyes]. A. Schaefer, Assr. to Northwest Process Co. U.S.P. 1,342,721, 8.6.20. Appl., 25.1.17.

AN evaporating chamber contains a stacked coil of steam pipes surmounted by a perforated distributor which distributes the liquor over the pipes in the form of a thin sheet. A valved discharge pipe at the bottom of the evaporating chamber communicates with a residuum chamber below, in which the liquor is neutralised and from which it is led to the fermenting vats. A saturation tank, in which the sulphur dioxide evolved is absorbed in water, is connected with the evaporating chamber and also with a vacuum pump which maintains a reduced pressure in the evaporator.—J. H. L.

Preparing cellulose acetate for dyeing. U.S.P. 1,366,023. *See* VI.

Celluloid. U.S.P. 1,364,342. *See* XXI.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Sulphur dyes; Process for rapidly developing the full bright tone of fabrics dyed with ——. E. Justin-Mueller. Soc. Ind. Mulhouse. Sealed Note No. 1804, 4.11.08. Rev. Gén. Mat. Col., 1921, 25, 5.

THE dyed fabric is treated for 10—20 mins. in a cold bath containing 2—3% of sodium bisulphite of 38° B. (sp. gr. 1·36) and 1—1½% (on the weight of fabric) of caustic soda of 38° B., mangled and dried without washing. The bath must be alkaline to Brilliant Yellow test paper.—A. J. H.

Sulphur dyestuffs; Process for printing coloured discharges by means of ——. E. Justin-Mueller. Rev. Gén. Mat. Col., 1920, 24, 85—86.

A SUITABLE printing paste is prepared by mixing 20 c.c. of caustic soda of 38° B. (sp. gr. 1·36) with the dyestuff, adding 250 c.c. of boiling water and 100 g. of dextrin, and heating the mixture for 20—30 mins. on a water bath until the reduction of the dyestuff is complete. For difficultly reducible dyes, the addition of 20 g. of sugar, glucose, or molasses etc. is necessary. For printing on white grounds, the mixture is diluted to 1 l. with neutral starch thickening containing 15 g. of Hydraldite C extra. A greater amount of Hydraldite must be used for the discharging of grounds dyed with azo dyestuffs. Good results are only obtained if the printing paste is not strongly alkaline and if the reducing agent used is not easily oxidisable. The printed fabric is steamed for 3—4 mins. at 102° C., washed, and soaped.—A. J. H.

Battick printing. L. Kollmann. Textilber., 1920, 1, 149—151. Chem. Zentr., 1921, 92, II., 35—36.

THE influence of the previous preparation of cloth for battick printing has been investigated. Mercerisation affects not the nature but only the depth of shade of the ground and grain. Alkaline treatment gives a clear vigorous grain. For "throwing up" wax reserves, gums and dextrins are satisfactory. Paraffin-colophony wax reserves are

best printed at 75°—80° C. in order to obtain clear effects. In breaking, the reserve must be actually broken and not merely bent. Breaking is best conducted under cold water since reserves broken in air tend to re-unite and so render dyeing more difficult. Dyeing should quickly follow breaking. The mercerisation of waxed fabrics allows special effects to be obtained.—A. J. H.

Patents.

Bleaching treatment of open fabrics; Apparatus for ——. E. W. Hunt. E.P. 156,359, 25.10.19.

The fabric is plaited down full width into a wagon having a perforated bottom, and pressed down by means of an open grid cover. The two ends of the wagon are then screwed towards each other so that the fabric is compressed. The wagon is run into a horizontal type of kier and liquor is passed upwards through the fabric.—A. J. H.

Dyeing textile fabric; Method and product for ——. J. W. Fries. U.S.P. 1,341,637, 1.6.20. Appl., 13.6.19.

A mixture of indigo paste and logwood extract can be prepared in the form of a dry powder soluble in soap solution and in alizarin (Turkey-red) oil. The logwood extract should be freshly made, or, if in an oxidised condition, should first be treated with a small quantity of yeast. Fabrics are dyed by padding or immersion in a solution of the mixed dyestuff and the colour is developed by treatment with salts of copper, iron, or nickel.

Fabric [silk and the like] pieces; Plant for treatment of ——. F. J. B. Knibiehler. U.S.P. 1,365,175, 11.1.21. Appl., 5.12.19.

The machine consists of a number of compartments which may be separated or not as desired and which contain the fabric to be treated. Conduits are arranged so that a controlled amount of liquid is delivered to each compartment, and means are provided for guiding the fabric therein.—A. J. H.

Dyeing machine. E. W. Morgan. U.S.P. 1,365,936 18.1.21. Appl., 11.10.20.

A barrel is provided with perforated partitions on opposite sides of its axis and liquid is sprayed on to the goods in the middle part of the barrel. Means are provided for revolving the barrel intermittently and for holding it stationary while the liquid is being sprayed on to the goods. A steam heating device is arranged round the barrel.—A. J. H.

Cellulose; Process for preparing —— for dyeing. E. Prince, Assr. to Soc. Chim. des Usines du Rhône (anc. Gilliard, P. Monnet et Cartier). U.S.P. 1,366,023, 18.1.21. Appl., 25.6.20.

Cellulose acetate is treated before dyeing with a relatively concentrated aqueous solution of alkali salts to which an alkali has been added.
—A. J. H.

[Cotton-silk and cotton-wool] union dyeing with sulphur dyestuffs; Process for —— whereby the wool or silk remains unstained. Farbenfabr. vorm. Bayer und Co. G.P. 326,649, 18.9.14.

Before dyeing, the union fabric is treated with tannic acid and a fixing agent such as tartar emetic or formaldehyde.—A. J. H.

Fast shades on vegetable fibres; Production of —— and [azo] dyestuffs therefor. H. Levinstein and J. Baddiley. U.S.P. 1,365,706, 18.1.21. Appl., 14.2.16.

See E.P. 8569 of 1914; J., 1915, 709.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

[Sulphuric acid manufacture;] The chamber process [for ——] under tropical conditions. W. H. Mawdsley. Austral. Inst. Min. and Met. Chem. Trade J., 1921, 68, 133—134.

A plant for the chamber process at Mount Morgan consisted of 7 chambers, 1 Glover, 2 Gay-Lussac towers, and 1 pipe column, the whole being run as one unit, and the furnace comprised one brimstone burner and four pyrites kilns. Records of running during one winter month, and one summer month, showed yields of 91·40 and 86·6% respectively, calculated on sulphur burned. To examine the effect of the acid on lead, strips of English and Australian lead, of best "chemical" quality, were suspended in each chamber; the average losses per annum were 11·9 and 11·2%, and total losses in three years were 29·49 and 27·72% respectively. "Creeping" of the lead was a source of trouble; it was to some extent obviated by rolling the sheets thicker for 2 ft. from the end. To support the lead when creeping had begun, provision was made to allow the horizontal supporting rails to be lowered. A device used for obtaining a fair sample of acid from different layers consisted of a pipe fitting closely in a copper cylinder, both pipe and cylinder having a vertical row of holes. These holes were caused to register for the purpose of taking a sample; and the pipe was turned so as to close the holes in the cylinder as the sample was withdrawn.
—W. J. W.

Arc process [for fixation of nitrogen]; Power cost in the ——. T. C. Hagemann. Chem. Trade J., 1921, 68, 170.

Allowance being made for auxiliary use of power and losses in absorption, the yield per k.w.-year in the arc process of nitrogen fixation amounts to only 115 kg. of fixed nitrogen compared with 450—500 kg. yielded by the cyanamide process. Graphs are given showing the cost of energy in the arc process as a percentage of the market price, the latter being taken as either £150, £100, or £73 16s. per ton of combined nitrogen. Cheap water power is taken as costing £1 4s. per k.w.-year, average cost of water power is estimated at £2 per k.w.-year, and steam-generated power at £3 15s. per k.w.-year. With an average pre-war price of £2 per k.w.-year for power, power charges amounted to 23·5% of the selling price, £73 16s. per ton of combined nitrogen. At a power cost of £2 6s. per k.w.-year, power charges amount to 15% and 20% respectively of the market prices, £150 and £100 per ton of combined nitrogen. In the arc process for manufacturing calcium nitrate, 15% of the yield is obtained as sodium nitrite, the market price for the combined nitrogen of which is about 67% more than of that in calcium nitrate.
—J. S. G. T.

Hydrocyanic acid; Preparation of anhydrous ——. K. Ziegler. Ber., 1921, 54, 110—112.

Gattermann's process is modified by the replacement of potassium ferrocyanide by sodium cyanide; with the apparatus described, about 1 kg. of sodium cyanide can be used at a time, the yield of hydrocyanic acid being 90% of that theoretically possible and the cost about $\frac{1}{4}$—$\frac{1}{3}$ of that of the older method. A glass flask of 5 l. capacity is provided with a rubber stopper with three holes. The first of these serves for connexion with the Gattermann air condenser and apparatus; the second holds a dropping funnel and the third a mercury safety-tube to which a second dropping funnel is attached by means of a side-tube. The ends of the dropping funnels are brought close together and immediately

above a small filter funnel which is fastened to the underside of the stopper by a stout wire; the stem of the funnel is bent in the form of a U and cut off so that the end is 0·5—1 cm. below the rim of the funnel. Concentrated sodium cyanide solution and an equimolecular amount of sulphuric acid (1:1) are allowed to flow into the funnel simultaneously; hydrocyanic acid is evolved immediately and uniformly and reaction is practically complete in the funnel itself, so that fresh solutions are continuously brought into contact with one another, whilst the bisulphate solution drops into the flask. After addition of the reagents is complete, the remainder of the hydrocyanic acid is driven into the receiver by heating the contents of the flask to the boiling point. Anhydrous hydrocyanic acid can be preserved unchanged for months if sealed in a glass vessel with a little calcium chloride.—H. W.

Halogen compounds; Dissociation of ——. A. von Weinberg. Z. Physik, 1920, **3**, 337—342.

The heats of dissociation of the following alkali salts have been calculated as: LiCl, 193·2; LiBr, 150·1; LiI, 129·0; NaCl, 181·4; NaBr, 140·1; NaI, 120·9; KCl, 183·9; KBr, 144·2; KI, 126·6; RbCl, 183·8; RbBr, 145·0; RbI, 127·9; CsCl, 184·2; CsBr, 145·8; CsI, 129·8; and the heats of sublimation as NaCl, 48·8; NaBr, 45·7; NaI, 43·3; KCl, 48·2; KBr, 45·2; KI, 449. (*Cf.* J.C.S., Mar.)—J. F. S.

Aluminium nitrate; Hydrates of ——. K. Inamura. Mem. Coll. Sci., Kyoto, 1920, **4**, 105—112.

Experiments on the equilibrium in the system $H_2O-Al_2(NO_3)_6-HNO_3$ at 25° C. showed that three hydrates of aluminium nitrate exist, with $18H_2O$, $16H_2O$, and $12\ H_2O$ respectively. The first is stable in nitric acid below 73% in strength, the second in 73—81% acid, and the last in acid stronger than 81% up to 90·5%, the limit of the experiments. A curve is given showing the rapid fall in solubility of alminium nitrate in nitric acid of increasing strength up to 60%, from which point the subsequent change is slight.—E. H. R.

Basic exchange in silicates. E. Ramann and H. Junk. Z. anorg. Chem., 1920, **114**, 90—104.

In continuation of previous work (J., 1916, 1129; 1919, 174 A) the formation of magnesium permutite by the action of magnesium salts on ammonium, sodium, and potassium permutites was studied. As in other cases, the reaction is ionic, and there is no evidence of physical adsorption. Pure magnesium permutite could not be prepared, not more than half of the bases present in the permutite being replaced by magnesium. The whole of the ammonium could not be displaced from ammonium permutite by treatment with carnallite ($MgCl_2+KCl$) or kainite ($MgSO_4+KCl$) mixtures. Mixed salt solutions decompose the permutite to some extent, especially solutions containing magnesium or ammonium.
—E. H. R.

Iron oxides; Reversible reactions of carbon monoxide with ——. G. Chaudron. Comptes rend., 1921, **172**, 152—155.

Ferric oxide is reduced to the magnetic oxide by carbon monoxide. Beyond this stage the equilibrium depends on the temperature. Below 580° C. there is a single system corresponding to the equation $Fe_3O_4+4CO \rightleftarrows 3Fe+4CO_2$. Above 580° C. there are two equilibria before arriving at iron, namely, $Fe_3O_4+CO \rightleftarrows 3FeO+CO_2$, and $FeO+CO \rightleftarrows Fe+CO_2$. The three solid phases co-exist in equilibrium at 580° C. Below 580° C. ferrous oxide is unstable, and is transformed into a mixture of iron and the magnetic oxide, $4FeO \rightleftarrows Fe_3O_4+Fe$.—W. G.

Thorium hydride; Existence of a gaseous ——. A. Klauber and J. M. von Mellenheim. Z. anorg. Chem., 1920, **113**, 306—316.

By a method similar to that employed by Paneth and others for detecting hydrides of lead and bismuth (J., 1920, 747 A), the existence of a gaseous hydride of thorium has been established. In a Marsh tube the hydride is decomposed, forming at first a dark brown deposit, afterwards changing to dark grey with a metallic appearance. The deposit was identified as thorium by its reactions. The hydride is very unstable, and its composition could not be determined.—E. H. R.

Protactinium; Properties of ——. *II. Life period and content in uranium minerals.* O. Hahn and L. Meitner. Ber., 1921, **54**, 69—77.

The half-life period of protactinium has been calculated by separating the latter from uranium salts of approximately known age (three preparations, one of the nitrate at least 20 years old, the second of the nitrate at least 52 years old, and the third consisting of a mixture of yellow uranium oxide and uranium acetate each about 60 years old) and measurement of its activity in comparison with that of uranium, the mean of three concordant experiments being about 12,000 years. This value is to be regarded as the lower limit. From this datum and the known disintegration ratio of the actinium to the uranium series it is calculated that a given uranium mineral contains 72 mg. of protactinium per ton of uranium, the corresponding figure for radium being 330 mg. (*Cf.* J.C.S., Mar.)—H. W.

Carbon; Softening of ——. J. Gmachl-Pammer. Monatsh., 1920, **41**, 467—476.

The results of the author's experiments on the behaviour of carbons of various kinds when heated electrically show that carbon containing impurities may be made to bend at a distinctly, although not greatly, lower temperature than the pure element. Graphite rods soften only at a far higher temperature than arc carbons, confirmation of this observation being found in the fact that protracted heating of arc carbons, which converts the latter into graphite, raises the softening point to a marked extent.—T. H. P.

Decomposition of formic acid. Muller and Peytral. *See* XX.

Precipitation of iron from hydrochloric acid solution. Patten and Mains. *See* XXIII.

Chromic acid. Kolthoff. *See* XXIII.

Patents.

Sulphuric acid; Manufacture of ——. South Metropolitan Gas Co., and P. Parrish. E.P. 156,328, 6.10.19.

To promote reaction between the sulphurous gases and the nitrous vitriol, the latter is passed through a closed tank, which is subdivided into compartments by partitions depending from the roof. The lower edges of these partitions are serrated and are immersed in the nitrous vitriol to a depth not exceeding 4 ins., the level of the acid being kept just above the recesses of the serrations. The sulphurous gases enter at one end of the tank and, after bubbling under each partition, escape at the other end.—W. J. W.

Sulphuric acid; Process for raising the efficiency of Reed. U.S.P. 1,363,918, 28.12.20. Appl., 21.8.18.

Concentrated sulphuric acid is produced by heating a mixture of air, sulphur dioxide, and a nitrogen oxide, absorbing the gaseous products of reaction in concentrated sulphuric acid, and then removing the nitrogen oxides from it.—W. J. W.

Sulphuric acid; Process for raising the efficiency of plant for manufacture of —— by the contact process. M. Leeck. G.P. 307,092, 16.1.18.

One fan is placed between the burners and the purification plant for the sulphurous gases, and a second between the contact chamber and the absorption plant. Through the double control the pressure and the gas composition can be regulated as desired in all parts of the plant.—C. I.

Sulphuric acid; Apparatus for concentration of ——. S. Barth. G.P. 304,343, 14.7.15.

The concentration vessel has, throughout its whole length, cross divisions over which the acid flows, the division walls being provided with perforations opposite each other. The sections formed in this way are connected by separate pipes with the gas exit main, and are also provided with side openings for cleaning.—C. I.

Ammonia; Direct oxidation of ——. L. Duparc and C. Urfer. E.P. 133,041, 24.9.19. Conv., 24.9.18.

A mixture of 4 vols. of ammonia and 7 vols. of oxygen is passed in an undried condition, at a comparatively high velocity, over a catalyst of rhodium black or asbestos containing 3—5% of rhodium, the reacting gases being heated to 500°—650° C. The formation of ammonium nitrate and nitrite is thus avoided, and a yield of 97%—100% of nitrogen peroxide is obtained.—W. J. W.

Lead sulphate; Process for making ——. P. A. Mackay. E.P. 155,945, 18.10.19.

At an initial temperature of 150° C., lead is rapidly dissolved by oleum, and when reaction has begun, complete conversion into lead sulphate takes place without further application of heat, or at least at a temperature not exceeding 100° C. If the lead is first coated with an electro-negative metal, such as mercury or copper, by treatment with a metallic salt, or if such metals or their salts are added to the oleum during the operation, the working temperature is reduced to 90°—100° C., with violent exothermic reaction. The lead sulphate is precipitated by diluting the solution.—W. J. W.

Sulphur dioxide; Composition for liberating ——. L. G. Wesson. U.S.P. (A) 1,356,029 and (B) 1,356,030, 19.10.20. Appl., 31.5 and 12.6.19.

(A) A mixture which is stable while dry but decomposed by damp air, is composed of a solid, hygroscopic acid material and a solid metabisulphite. (B) A mixture of a dry solid pyrosulphate and bisulphite or metabisulphite.

Carbides; Apparatus for the production of nitrogen compounds from metal ——. V. Thrane. U.S.P. 1,364,157, 4.1.21. Appl., 9.1.18.

A furnace for treating carbides with nitrogen comprises a compartment within which is a movable table, and means are provided for delivering a layer of inert material upon the table and a layer of carbide upon the inert material, and for passing a current of nitrogen into the chamber in a direction opposite to that in which the table moves.
—J. H. L.

Double sulphates [sodium ammonium sulphate]; Process of splitting —— and washing the products. G. N. Vis. U.S.P. 1,364,822, 4.1.21. Appl., 18.12.18.

Sodium ammonium sulphate is dehydrated, heated in a solution of ammonium sulphate, the precipitated anhydrous sodium sulphate is removed, and the solution crystallised, giving ammonium sulphate mixed with about 10% of sodium sulphate.—C. I.

Ammonium sulphate; Process for transforming free or combined ammonia into ——. G. N. Vis. U.S.P. 1,366,301, 18.1.21. Appl., 25.10.18.

Ammonia (free or combined) mixed with inert gas or steam is absorbed by means of sodium bisulphate practically free from uncombined sulphuric acid to obtain double sodium ammonium sulphate, and the resulting solution is diluted and cooled, whereby sodium sulphate crystallises out as $Na_2SO_4,10H_2O$.

Gas; Washing of —— with acid for ammonia recovery etc. C. Still. G.P. 328,394, 9.8.19.

In an ammonium sulphate saturator with several vertical pipes dipping into a single vessel, each pipe has a constriction a short distance above the surface of the liquid, at which point any pipe can be shut off as desired.—C. I.

[Producer] gas and cyanides; Manufacture of ——. R. Franchot, Assr. to Ferro Chemicals, Inc. U.S.P. 1,364,838, 4.1.21. Appl., 8.7.19.

Producer gas is generated at a temperature sufficient to slag the ash in the fuel and, without cooling, is passed over a charge of shaped pervious masses formed of iron, carbon, and a relatively small proportion of alkali carbonate.—C. I.

Ammonia [from cyanamides]; Preparation of ——. W. O. Snelling. U.S.P. 1,365,739, 18.1.21. Appl., 24.3.16.

A suspension of the cyanamide in cold water is brought into heat-interchanging relation with the hot reaction products of a preceding operation on a similar suspension.—W. E. F. P.

Chlorates, bromates, and iodates; Manufacture of ——. H. Schulz. G.P. 328,211, 15.6.15.

Halogens and air at atmospheric or increased pressure are passed into an aqueous suspension of any suitable oxide or hydroxide in presence of a catalyst, such as manganese dioxide; or air may be passed into a solution in which the catalyst is suspended and in which a halogen is being generated. A high yield of chlorates etc. is obtained, whereas without the use of air or a catalyst, only one-sixth of the halogen is converted into chlorate, bromate, or iodate.—C. I.

Hydrogen peroxide; Method of making ——. R. Jacquelet. U.S.P. 1,364,558, 4.1.21. Appl., 19.11.19.

Barium peroxide is added to a weak solution of hydrochloric acid, and nitric acid equivalent to the hydrochloric acid is then added to the mixture. This process is repeated until hydrogen peroxide solution of the desired strength, containing a small amount of barium chloride, is obtained.—W. J. W.

Boron carbide; Manufacture of —— especially in shaped pieces. E. Podszus. G.P. 327,509, 23.3.16.

Boron nitride is changed by carbon at the temperature of the electric arc to a coherent mass. Carbon monoxide, carbon and ammonia, or hydrogen and carbon bisulphide can also be used as reducing agent. For this reaction a temperature of 2000° C. is required; on heating to a considerably higher temperature the carbide melts and gives a product suitable for use as an abrasive.—C. I.

Argon and other rare gases of the atmosphere; Purification of ——. E. Barbet et Fils et Cie. E.P. 129,989, 15.7.19. Conv., 17.7.18.

In the process described in E.P. 131,321 (J., 1919, 766 A), the liquid argon, containing a low percentage of nitrogen, which is drawn off from the air rectifier, passes into another plate rectifying column, which is also heated by a worm containing cold gaseous nitrogen under a pressure of 4—5 kg. per sq. cm. Part of the oxygen which is separated is

drawn off at the lower portion, while the remainder condenses and vaporises the argon and nitrogen in the upper portion of the rectifier. These vapours pass into a condenser immersed in liquefied nitrogen drawn from the top of the air rectifier, and thence to a separator, from which liquid argon is returned to the top plates of the argon rectifying column, while uncondensed vapours are passed into the air rectifying column at a point above that where the liquid argon is drawn off. The liquid nitrogen from the heating worm is mixed with that from the worm in the air rectifier and passed to the upper plates of the latter. Neon and helium, together with some hydrogen, which are mixed with the nitrogen from the air rectifier, are first compressed and cooled, and then passed into a rectifier where the nitrogen is collected at the bottom, while the vapours of neon, helium, and hydrogen escaping at the top pass through a coil immersed in nitrogen drawn from the lower part of the column. Neon is thus liquefied and is drawn off, and the hydrogen escapes with the helium in a gaseous state and is separated from it by passing over wood charcoal or by the eudiometric method. Xenon and krypton, which are drawn off from the bottom of the air rectifier, are separated from oxygen in a column from which the latter is separated in the upper portion by heating with the krypton vapours, and then purified by liquid nitrogen; the xenon and krypton are separated at the top and bottom, respectively, of the lower half of the column, which is heated by a worm through which air passes at normal temperature.—W. J. W.

Hydrogen and mixtures of hydrogen and nitrogen; Production of —— [from gases from blast furnaces and electric smelting furnaces]. C. Toniolo, and Officine Elettrochim. Rossi. E.P. 152,975, 24.12.19. Conv., 21.10.19.

GASES from blast furnaces and electric smelting furnaces are treated with steam in presence of a catalyst, such as iron oxide with or without an alkali metal oxide, chromium oxide, or an alkaline-earth oxide, and the hydrogen, or hydrogen and nitrogen mixture, is freed from carbon monoxide, carbon dioxide, and steam by suitable methods. The gases so produced may be employed for the hydrogenation of fats, synthetic manufacture of ammonia, or preparation of explosive mixtures for internal combustion engines, supplementary hydrogen or nitrogen from another source being added, if desired.—W. J. W.

Hydrogen; Manufacture of —— by means of silicon and its alloys. G. F. Jaubert. U.S.P. 1,366,185, 18.1.21. Appl., 29.7.20.

SUFFICIENT water is added to powdered ferrosilicon to decompose the contained phosphide and produce a pasty mass, and the latter is added to a solution of caustic alkali in a hydrogen generator.
—W. E. F. P.

Hydrogen and carbonates; Process for the simultaneous manufacture of compressed ——. J. Billwiller. G.P. 328,637, 3.10.16.

PEAT, lignite, or the like, is oxidised with solutions or suspensions of basic substances at about 300° C., under pressure, either alone or in the presence of a catalyst.—C. I.

Sulphur; Method of and apparatus for separating —— from sulphur ores. N. E. Katz, Assr. to H. M. Little. U.S.P. 1,365,922, 18.1.21. Appl., 24.6.19.

THE ore is heated with water in an autoclave until the sulphur is melted by the steam generated.
—W. E. F. P.

Graphite; Manufacture of —— in the electric furnace. C. Conradty. G.P. 327,911, 2.11.17.

THE conversion of coal, coke, or anthracite into graphite proceeds more readily at a pressure less than atmospheric. Such a pressure is obtained in practice by enclosing the furnace in a strong sheet iron vessel and exhausting the latter.—C. I.

Sulphuryl chloride; Manufacture of ——. T. H. Durrans, Assr. to A. Boake, Roberts and Co. U.S.P. 1,364,738, 4.1.21. Appl., 28.5.18.

SEE E.P. 124,542 of 1918; J., 1919, 361 A.

Ammonium sulphate; Process of making ——. Process of preparing pure ammonia from ammonia-containing gases. G. N. Vis. U.S.P. 1,366,302—3, 18.1.21. Appl., 3.12.19.

SEE E.P. 136,833—4 of 1918; J., 1919, 516 A, 741 A.

Hydrogen and carbon monoxide; Treatment or purification of mixtures of —— for the separation therefrom of the latter. J. Harger and H. Terrey. U.S.P. 1,366,176, 18.1.21. Appl., 18.4.18.

VIII.—GLASS; CERAMICS.

Porcelain; Transparency and refractoriness of ——. T. Hertwig. Sprechsaal, 1921, **54**, 11—12.

FIVE porcelain mixtures with a firing temperature corresponding to Seger cone 9 (1280° C.) were prepared from Zettlitz kaolin, Rörstrand felspar, Pleystein quartz, calcite, and zinc oxide. The first, corresponding to the formula, $(0{\cdot}65K_2O,0{\cdot}35CaO, ZnO),2{\cdot}8Al_2O_3,14SiO_2$ (acid ratio 1:1·49) had a shrinkage of 12·7% and was transparent. Small dishes with flat lids of normal thickness were cast quite satisfactorily, but very thin lids sank slightly. Two mixtures of the formulæ $(0{\cdot}8K_2O,0{\cdot}2CaO,ZnO), 2{\cdot}8Al_2O_3,17SiO_2$ (acid ratio 1:1·8) and $(0{\cdot}8K_2O, 0{\cdot}2CaO,ZnO),2{\cdot}8Al_2O_3,18SiO_2$ (acid ratio 1:1·91) were not refractory, and similar lids made of them collapsed; this is ascribed to the high content of alkali in conjunction with a high acid ratio. A mixture of formula, $(0{\cdot}83K_2O,0{\cdot}17CaO,MgO, FeO),3{\cdot}59Al_2O_3,16{\cdot}36SiO_2$ (acid ratio 1:1·38) was highly transparent and retained its shape completely at Seger cone 14 (1410° C.). A mixture of formula $(0{\cdot}65K_2O,0{\cdot}35CaO,MgO,FeO),3Al_2O_3,11SiO_2$ (acid ratio 1:1·1) was a biscuit mass, with a good matt appearance but of low transparency. The results confirm Dorfner's statement (J., 1916, 602) that excellent porcelain to be fired at Seger cone 9 can be made, but to ensure the ware retaining its shape perfectly, a high potash content must accompany a low acid ratio, and the quartz content must be kept low or the ware will have a greasy appearance. German porcelains are too rich in alumina and quartz and often too low in potash, but if the proportions are altered whilst ignoring the acid ratio the product will not be sufficiently refractory. A glaze suitable for the first mixture mentioned above is composed of grog from the same mixture 22·54%, Rörstrand spar 22·30%, dolomite 9·61%, calcite 7·27%, zinc oxide 2·05%, calcined Zettlitz (Zebisch) kaolin 8·49%, Pleystein quartz 27·74%, corresponding to $(0{\cdot}2K_2O,0{\cdot}2MgO,0{\cdot}5CaO,0{\cdot}1ZnO), 0{\cdot}5Al_2O_3,4SiO_2$. The inclusion of a little grog increases the adhesion of the glaze and the zinc oxide increases its whiteness. No raw clay is needed.
—A. B. S.

PATENTS.

Reflecting surfaces on glass; Production of —— by means of metals in the platinum group. J. Rheinberg. E.P. 156,472, 16.9.20.

HOMOGENEOUS, structureless mirrors are produced by coating glass with a film of collodion containing a salt of platinum, or of a metal of the platinum group, and submitting the coated glass to the requisite temperature, *e.g*, 600°—750° C., in a furnace. The necessary temperature is usually lowered about 30° C. by the addition of a small quantity of a lead or bismuth salt to the platinum or other salt.—H. S. H.

Abrasive stone. Norton Co., Assees. of J. H. Stean. E.P. 139,502, 25.2.20. Conv., 26.2.19.

AN abrasive stone, which can be used without oil, is composed of a fast-cutting abrasive such as corundum, emery, crystalline alumina, silicon carbide, etc., in very fine powder, with less than 15% of graphite as a non-oily lubricating filler and 5—30% of an organic binding agent such as shellac, resin, bakelite, celluloid, casein, rubber, or rubber substitute. One side of the stone may be composed of abrasive, 80%, and binder, 20%, and the other side of abrasive, 65%, graphite, 10%, binder 25%. The materials are mixed, moulded, heated to 350°—375° F. (about 180°—190° C.) for about 2 hrs. to melt the binder, then subjected to a pressure of about 1 ton per sq. in., and afterwards baked at about 400° F. (200° C.).—A. B. S.

Abrasive and refractory article and method of producing same. A. H. Andersen, Assr. to Norton Co. U.S.P. 1,364,849, 4.1.21. Appl., 17.4.19.

A COMPOSITION for forming ceramic articles comprises refractory or abrasive crystalline grains, a plastic clay, water, and an oily lubricating agent. —H. S. H.

Refractory materials for furnace linings; Manufacture of ——. A. Rollason. E.P. 156,447, 21.4.20.

CRUSHED dolomite or magnesite is mixed with 5—10% of crushed basic slag and passed through a basic-lined rotary kiln, internally fired to approximately 1800° C. The material leaving the kiln is passed into a closed chamber, where it is annealed and cooled slowly out of contact with the atmosphere, by which treatment its capacity of "knitting together" when mixed with any suitable binding material is considerably increased.—H. S. H.

Refractory material; Manufacture of ——. J. F. Mollen and W. W. Patnoe, Asars. to The Dolomite Products Co. U.S.P. 1,365,336, 11.1.21. Appl., 2.2.20.

REFRACTORY material suitable for furnace linings is made by adding a small percentage of common salt to a slurry of raw dolomite, and then passing the mixture through a rotary kiln operated at a temperature sufficiently high to calcine the dolomite and drive off practically all of the salt.—H. S. H.

Refractory oxide; Method of converting ——. Method of shrinking magnesia. L. E. Saunders, Assr. to Norton Co. U.S.P. (A) 1,352,387 and (B) 1,352,388, 7.9.20. Appl., (A) 15.4.19, (B) 28.7.17. (B) Renewed 17.2.20.

FOR (A) shrinking, agglomerating, sintering, or fusing refractory oxides, or (B) shrinking magnesia, the material is heated locally by the passage of an electric current through, for instance, a thin carbon rod embedded in the charge above the median horizontal line. The carbon burns away, and the charge in the vicinity agglomerates and becomes electrically conductive and then serves to carry the current.

[Silica] brick and process of making the same. F. Orth. U.S.P. 1,363,264, 28.12.20. Appl., 29.3.17. Renewed 7.5.20.

A MIXTURE of pure silica (the largest particles passing a 40-mesh screen and the whole graded so as to secure a minimum percentage of voids) with 2—5% of hydrated lime is moulded, treated with steam at a pressure of 125 lb. per sq. in. for 10 hrs., and afterwards fired for 8 days at 2800°—3000° F. (1540° C.—1650° C.).—A. B. S.

Radium luminous article and method of producing same. E. O'Hara. U.S.P. 1,364,951, 11.1.21. Appl., 26.12.19.

THE article to be rendered luminous is coated with a paste containing a mixture of a radium luminous material, *e.g.*, radioactive zinc sulphide crystals, and a flux or glaze, and then heated in a muffle furnace so as to melt the glaze.—B. V. S.

Gas-fire radiants. E.P. 156,416. *See* IIB.

Boron carbide. G.P. 327,509. *See* VII.

Eliminating volatile matter from clay. U.S.P. 1,363,387. *See* X.

IX.—BUILDING MATERIALS.

PATENTS.

Insulating and building material. Fabriks Aktiebolaget Kronsten, Assees. of T. A. Eklund and C. G. Löfveberg. E.P. (A) 140,431, 17.3.20, and (B) 142,111, 21.4.20. Conv., (A) 19.3.19, (B) 24.4.19.

(A) A POROUS insulating material is produced by intimately mixing fresh-water marl with 1—15% of cellulose freed from incrusting substances. Bricks can be moulded or pressed from the wet material. (B) Cellulose-containing material which is not free from incrusting substances (such as moss-litter, peat fibre, kelp, straw, chaff, hemp, flax, mechanical wood pulp, etc., can replace the cellulose freed from incrusting substances in (A). The results are then improved by the addition of 5—15% of fibrous materials not containing cellulose (*e.g.*, asbestos, slag wool, cow-hair, etc.).—H. S. H.

Porous stones for thermal insulating purposes; Manufacture of ——. H. J. C. Forrester. From Internationalt Isolations Komp. A./S.-Ikas. E.P. 156,442, 7.4.20.

AN insulating material is obtained by mixing ground "moler" (diatomaceous earth) with a mixture of cork and sawdust, moulding to the required shape, and burning.—H. S. H.

Asbestos-cement and like cement-mixtures or compounds; Method of and means to cure, colour, or otherwise treat sheets or other articles made of ——. W. Pattison. E.P. 155,883, 11.9.19.

ARTICLES made of asbestos-cement and the like are cured and/or coloured by placing them in a water-tight chamber in which they are subjected successively to various treatments, *e.g.*, heated by means of steam pipes, treated with moist air, neutralising liquids, colouring fluids, etc. The liquids are circulated in a series of similar chambers which are used simultaneously, but the articles remain in the chamber in which they are placed until their treatment is finished.—A. B. S.

Coating process [for cement]. L. A. and A. J. Sanders. U.S.P. 1,364,587, 4.1.21. Appl., 10.12.15.

SURFACES of calcareous cements of the nature of hydraulic cement, and having an alkaline reaction because of the lime present, are treated with an aqueous solution of a neutral salt of a heavy metal forming coloured oxides and containing an acid not

decomposed by the lime of the surface. A deposit of a coloured metal oxide is formed in the surface layer by interaction between the lime and the acid contained in the salt.—H. S. H.

Slag. E.P. 150,033. *See* IIA.

Peat. E.P. 155,895. *See* IIA.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron ores; Decomposition of oxide —— [*for analysis*]. F. Leteur. Ann. Chim. Analyt., 1921, **3**, 16—19.

Iron oxides which are difficult to obtain in solution may be dissolved readily by heating them in a closed flask at 60°—70° C. with concentrated hydrochloric acid, particularly if the latter has been saturated with hydrogen chloride just before use. The pressure developed is not great, and with reasonably strong flasks there is but little risk of breakage. —W. P. S.

Graphite; Solubility of —— *in molten iron.* R. Ruer and J. Biren. Z. anorg. Chem., 1920, **113**, 98—112.

The solubility of graphite in molten Swedish iron increases as the temperature is raised from 1152° C. to 2700° C. The solubility curve is linear from 1152° to 1700° C.; it then bends away from the concentration axis, slightly at first and then more strongly as the temperature increases. The concentration of the graphite eutectic at 1152° C. is 4·25% carbon, and that of the cementite eutectic at 1145° C. is 4·30% carbon. (*Cf.* J.C.S., Mar.)—J. F. S.

Aluminium; Purification and testing of ——. F. and W. Mylius. Z. anorg. Chem., 1920, **114**, 27—64.

When technically pure aluminium (Al 99·58%, Fe 0·18%, Si 0·22%, C 0·02%) was allowed to cool slowly, the portion first crystallising was purer than that which crystallised later, in which the iron and silicon became concentrated. From highly impure aluminium, however, impure crystals of high-melting alloys separated first. In the neighbourhood of its melting point technically pure aluminium becomes brittle, and can be granulated by stirring the metal during crystallisation. Such granulated metal can be almost entirely freed from iron by repeated extraction with dilute hydrochloric acid, which dissolves the impure "cement" material from the purer aluminium crystals. It is best to re-melt and re-granulate the metal between successive extractions. After four such treatments, from the above 99·58% material, an aluminium was prepared, in 50% yield, containing Al 99·9%, Fe 0·02%, Si 0·2%, C 0·01%. Purification to about the same extent was also effected by partially melting the aluminium in a reducing atmosphere and pouring off the lower melting portion from the purer aluminium crystals. The yield of purified metal by this process was low. With the object of devising a test which would indicate the probable behaviour of objects of technical aluminium under atmospheric influences, experiments were made on the action of solvents and oxidising agents on aluminium of different degrees of purity, in the form of castings, foil, or wire. A test was devised with a solution containing 2·0% of hydrogen peroxide and 1% of sodium chloride. The extent of attack by this reagent, as measured by the loss of weight of the sample after immersion for several days under standard conditions, diminishes, in the case of wire, as the purity of the metal is increased. The amount of attack is also much lessened by first removing the effect of cold-work by heating the metal for some time at 500° C. Another test which gave similar results, consisted in treating the sample to be tested in a test-tube with 10% hydrochloric acid and plotting the time-temperature curve. The rate of rise of temperature to a maximum was found to be a function of the physical and chemical properties of the aluminium. The most highly purified aluminium was scarcely attacked by 20% hydrochloric acid.—E. H. R.

Nolly's electric apparatus [*for the determination of carbon in metals*]; *Modifications of* ——. Bedin. Ann. Chim. Analyt., 1921, **3**, 15—16. (*Cf.*, J., 1911, 688, 1216.)

The modifications suggested are an adjustable resistance, a two-way tap on the vacuum flask, and the use of bismuth tetroxide in place of lead peroxide as oxidising agent. Much practice is required before trustworthy results can be obtained with the apparatus; concordant results cannot be obtained when the carbon content of a metal exceeds 3·5%. —W. P. S.

Iron oxides and carbon monoxide. Chaudron. *See* VII.

Basic slag. (1) Jones. (2) Bainbridge. (3) Stead and Jackson. (4) Robertson. *See* XVI.

Patents.

Cast iron; Manufacture of soft ——. T. Levoz. E.P. 140,756, 17.2.20. Conv., 27.3.19.

A mixture of hæmatite irons or hæmatite irons and scrap is melted in a converter with a surface blast of air until silicon is completely removed, then transferred to a furnace and heated to not exceeding 1550° C., after which the desired combined carbon content is obtained by the addition of reducers.—J. W. D.

Copper from nickel; Process for electrolytically separating ——. P. Goldberg. E.P. 145,600, 29.6.20. Conv., 9.7.18.

Anodes containing copper and nickel are treated electrolytically in hydrochloric acid or in an acid solution of a chloride in such a manner that the quantity of copper deposited at the cathode and the quantity dissolved at the anode are equal, the copper content of the solution being kept uniform and the nickel remaining in solution.—J. W. D.

Magnetic separators. F. Krupp A.-G. Grusonwerk. E.P. 147,546, 18.6.20. Conv., 11.7.19.

A magnetic separator of the revolving inductor ring type is mounted in such a manner that the whole apparatus, including the feeding device, the magnets, and the means for carrying away the separated material, is capable of being tilted about its driving shaft, without any relative displacement of the several parts, and without interfering with the driving gear.—A. R. P.

Welding of metal objects [*; Electric* ——]. C. F. Jacobs. E.P. 156,376, 12.11.19.

The objects to be welded are immersed in a bath of molten flux, which serves to convey the welding current. The current preferably passes also through one or both of the objects to be welded, and one or both of them are preferably removed from the circuit before the welding process is complete. —J. S. G. T.

Electric arc welding and like operations and electrodes therefor. C. J. Holslag. E.P. (A) 156,280 and (B) 156,476, 30.6.19.

(A) A twin or multiple electrode for arc welding etc., comprises two or more metal electrodes arranged adjacent to, but insulated from, each other, so that two closely adjacent arcs are produced having a common puddle of molten metal. The

electrodes are held together by a flux coating, wholly or partly surrounding them, and may be arranged in one or more planes. (B) A number of electrodes conveying currents of different phases are employed to produce separate adjacent arcs, after the manner described under (A).—J. S. G. T.

Arc-welding electrode. P. H. Brace, Assr. to Westinghouse Electric and Manufacturing Co. U.S.P. 1,363,636, 28.12.20. Appl., 12.5.19.

An arc-welding electrode comprises a sheath of welding metal enclosing a core of an alkaline-earth metal.—J. W. D.

Copper cable tubes and other metal articles; Apparatus for the manufacture of —— by electro-deposition. S. O. Cowper-Coles. E.P. 156,441, 26.3.20.

Apparatus for the manufacture of copper cable tubes etc. by electro-deposition comprises a vat having a central partition, rotary devices for rapidly circulating the electrolyte, and a number of cathode matrices, which are oscillated and moved up and down in the electrolyte in which the anodes are suspended. The circulating devices consist of a set of blades disposed vertically, united at their ends by rings, and secured at their centres to a spider disc mounted on a vertical shaft, the whole being mounted in a chamber having a hole at the bottom and a number of smaller holes at the top. Means are provided for continuously drawing off the electrolyte, filtering it, and returning it to the vat. —J. S. G. T.

Metals; Method of treating —— [in electric furnaces]. R. H. Bulley. U.S.P. 1,347,838, 27.7.20. Appl., 24.4.16. Renewed 5.8.19.

The metal is subjected to the influence of a relatively high voltage electric arc in an electric circuit of a given kilowatt load, and later for the final refining of the metal, the voltage in the circuit is reduced whilst retaining the load. In the latter stages the arc is shorter, and hence there is less destructive action on the roof of the furnace. —J. W. D.

Ore-concentrating apparatus. B. H. Dosenbach; E. M. Dosenbach, extrix. U.S.P. 1,354,031, 28.9.20. Appl., 28.1.18.

Air is forced through a chamber containing one of the usual modifying agents employed in flotation processes, *e.g.*, tar oil, alcohols, naphthylamine, nitronaphthalene, naphthol, etc., and the mixture of air and vapour is introduced, under regulated pressure, into ore pulp contained in a flotation cell of the Callow type.

Ore-concentration process. W. A. Scott. U.S.P. 1,365,281, 11.1.21. Appl., 8.7.19.

A freely flowing ore pulp is treated so as to produce therein bubbles containing a substance capable of reacting chemically with a substance present in the pulp to form a flotation agent. The bubbles with adhering solids are then separated from the remainder of the pulp.

Flotation of minerals. C. L. Perkins, Assr. to Metals Recovery Co. U.S.P. (A) 1,364,304, (B) 1,364,305, (C) 1,364,306, and (D) 1,364,858, 4.1.21. Appl., (A) (B) (C) 21.7.19, (D) 13.7.20.

The mineral pulp is treated with a small amount of (A) a non-oleaginous organic mineral-collecting agent which is substantially non-frothing, (B) an organic nitrogen compound containing two nitrogen atoms joined to each other, or (C) a hydrazine compound, and the resulting mixture is subjected to a froth flotation operation. (D) The pulp is treated with a small amount of a substantially non-frothing, non-oleaginous organic mineral-collecting agent, then with a substance having good frothing properties, and the resulting mixture is subjected to flotation.—A. R. P.

Flotation of minerals. C. L. Perkins and R. E. Sayre, Assrs. to Metals Recovery Co. U.S.P. (A) 1,364,307, (B) 1,364,308, and (C) 1,364,859, 4.1.21. Appl., (A) 11.11.19, (B) 25.3.19, (C) 13.7.20.

A small amount of (A) an organic nitrogen-sulphur compound, or (B) a thiourea compound, is added to the mineral pulp, which is then subjected to a flotation. (C) As a mineral-collecting agent a small amount of a non-frothing, non-oleaginous organic nitrogen-sulphur compound is added to the pulp, which is then treated with a substance having good frothing properties, and the mixture put through the flotation process.—A. R. P.

Alloy; Metal ——. J. E. Holder. U.S.P. 1,359,064, 16.11.20. Appl., 2.6.20.

An alloy of lead 30—50, copper 47—68, nickel 1—5, arsenic 0·5—1·5, manganese 2·5, phosphorus 0·5, and iron 0·5 pts.—J. W. D.

Alloys; Process of producing metallic ——. J. P. Arend. U.S.P. 1,363,382, 28.12.20. Appl., 21.3.18. Renewed 28.8.20.

To obtain alloys free from oxygen the material is treated during the melting-down operation with a reducing slag containing alkali manganosilicates. —J. W. D.

Zinc alloy. A. Tedesco, Assr. to Soc. Anon. Stabilimenti Biak. U.S.P. 1,364,654, 4.1.21. Appl., 11.4.19.

An alloy containing Zn 85%, Cu 2—8%, Al 2·5—7·1%, Ni 0·5—8%, together with small quantities of iron and manganese.—J. W. D.

Alloy. A. W. Clement, Assr. to The Cleveland Brass Manufacturing Co. U.S.P. 1,365,091, 11.1.21. Appl., 12.3.17.

An alloy of iron and chromium substantially free from carbon, oxides, and impurities is produced either by reducing a combined ore of iron and chromium, followed by decarburising the reduced metal by treatment with oxides of one or more of the component metals, or by decarburising an alloy of iron, chromium, and carbon. The resulting alloy is deoxidised by fluxing with calcium carbide. —J. W. D.

Aluminium alloy, and method of making same. A. De Lavandeyra. U.S.P. 1,365,178, 11.1.21. Appl., 7.8.19.

The alloy contains aluminium and smaller amounts of manganese, magnesium, copper, and chromium. —A. J. H.

Alloy. H. S. Foote, Assr. to Standard Chemical Co. U.S.P. 1,366,254, 18.1.21. Appl., 29.9.20.

An alloy of steel with uranium, silicon, and nickel. —J. W. D.

Metal-bearing ores or materials; Treatment of —— and recovery of the valuable or desired constituents thereof. E. A. Ashcroft. E.P. 156,866, 30.9.19.

The ore, suspended in a mobile fused melt, is treated in a converter with chlorine or a gas yielding chlorine, thus converting the metals into chlorides. Iron or manganese is converted into oxide by precipitating with magnesia, lime, or alkali oxide or carbonate, removing the insoluble gangue matter and the precipitated oxide of iron or manganese by filtration, fractionally precipitating the metals which it is desired to recover (for example, silver, lead, and zinc) by means of an alloy of magnesium, calcium, sodium, or potassium

with lead or zinc, and electrolysing the remaining chlorides with cathodes of the heavier metals so as to re-form the alloys for re-use and produce a cyclic process.—J. W. D.

Ores, minerals, and clays; Process for eliminating volatile matter and gases from ——. S. L. Boggs. U.S.P. 1,363,387, 28.12.20. Appl., 2.8.20.

THE material is roasted, crushed, and pulverised, and then agitated in a mixture of alum and water. —W. J. W.

Casting freely-oxidisable metals. H. E. Bakken, Assr. to Aluminium Co. of America. U.S.P. 1,363,384, 28.12.20. Appl., 15.1.20.

THE metal is cast in a mould made from sand which is free from water and which is rendered mouldable by being mixed with a non-aqueous liquid. —J. W. D.

Ores; Method of treating ——. G. Moore. U.S.P. 1,364,573, 4.1.21. Appl., 14.1.19. Renewed 20.7.20.

SULPHIDE ores are subjected in a closed container to the action of sulphuric acid and ozonised air under the influence of heat, the evolved sulphur dioxide being converted into sulphuric acid which is then returned to the container.—J. W. D.

Ores; Process of and apparatus for reducing and smelting ——. J. Lund. U.S.P. 1,365,113, 11.1.21. Appl., 26.6.16.

THE apparatus comprises a furnace having a reducing chamber, means for feeding ore and fuel to this chamber, also means for supplying compressed air to, and preventing free escape of gas from, the chamber, a smelting chamber communicating with the reducing chamber, and so constructed that a liquid resistance to compressed gases can be maintained between the two chambers. —J. W. D.

Nickel and cobalt; Process of separating ——. M. J. Udy and O. C. Ralston, Assrs. to Hooker Electrochem. Co. U.S.P. 1,365,358, 11.1.21. Appl., 3.7.19.

COBALT is precipitated from mixed nickel cobalt solutions by simultaneously subjecting the solution to the action of chlorine and an alkaline-earth carbonate at a temperature below that at which material precipitation of nickel occurs.—J. W. D.

Slag-pocket floor. S. G. Worton. U.S.P. 1,365,436, 11.1.21. Appl., 3.2.17.

A SLAG-POCKET is interposed between the regenerator of a regenerative furnace and a flue opening into the interior of the furnace. The slag-pocket has a removable hollow metal floor supported on a refractory bottom, with means for circulating a cooling medium within the hollow floor.—J. W. D.

Surface-alloyed metal. F. C. Kelley, Assr. to General Electric Co. U.S.P. 1,365,499, 11.1.21. Appl., 23.10.19.

To provide a metal with a surface-alloy of chromium the metal is heated in a non-oxidising atmosphere in contact with powdered metallic chromium to a temperature of at least 1200° C., but below the melting-point of the metal.—J. W. D.

Metal from ore; Method of obtaining ——. S. G. Musser. U.S.P. 1,365,844, 18.1.21. Appl., 19.1.18. Renewed 13.5.20.

METAL is obtained from ore by means of a centrifugal amalgamator, in which a hollow rotating column of ore is caused by centrifugal action to move through and in contact with a hollow body of mercury. The tailings are discharged in a direction opposite to the direction of rotation, so as to prevent close packing of the ore in the column. —J. W. D.

Magnetic qualities of magnetisable material; Process of improving the ——. Metropolitan-Vickers Electrical Co., Ltd., Assees. of T. D. Yensen. E.P. 141,348, 6.4.20. Conv., 4.4.19.

Electric [crucible] furnace. E. Assié. E.P. 141,352, 6.4.20. Conv., 9.8.17.

AN electric crucible furnace for making refractory products comprises a hearth and outer refractory casing of beaten graphite, an inner casing of agglomerated material such as calcined magnesia, dehydrated bauxite, carbon, or corundum dust, which is a conductor only at a high temperature, and a movable electrode, the whole being enclosed within a sheet metal casing.—J. S. G. T.

Electrodes of electrolytic cells; Protecting varnish for ——. T. A. Edison. U.S.P. 1,364,359, 4.1.21. Appl., 29.9.19.

A VARNISH for protecting electrodes of electrolytic cells is composed of a coumarone or paracoumarone resin.—J. S. G. T.

Electrolytic apparatus. W. E. Greenawalt. U.S.P. 1,365,032—4, 11.1.21. Appl., (A) 29.4.18, (B) 10.2.19, and (C) 13.6.14. (C) Renewed, 5.4.19.

(A) THE electrodes are so arranged in an electrolytic chamber that the electrolyte takes a sinuous path as it flows through the chamber. A gas is also passed through the chamber, and means are provided for spraying the liquid into the gas at the crests of the sinuous path. (B) An electrode consists of an interior support composed of sections bolted together internally with rods, and having metal sheets attached to the faces of the support. (C) A portion of the electrolyte is withdrawn from an electrolytic chamber and passed into a separate vessel in which a "finely divided sulphide reagent" is maintained in suspension in the electrolyte by agitation with an atomised gaseous reagent. The gas is atomised by leading it into the liquid below a rotating perforated agitator submerged in the liquid, and, after treatment with gas, the liquid is separated from insoluble matter and returned to the electrolytic chamber. —L. A. C.

Electrolytic cell. L. E. Ward, Assr. to The Dow Chemical Co. U.S.P. 1,365,875, 18.1.21. Appl., 13.12.18.

THE space between two plates in an electrolytic cell is closed laterally so as to form a chamber for the electrolyte. This chamber is divided into compartments by a metallic screen covered by a diaphragm Carbon electrodes project through the plates, one set of electrodes being connected with the screen. Means are provided for adjusting the height of electrolyte in the compartments.—J. S. G. T.

Electrical furnaces; Method for the heating of material or the performance of chemical processes in ——, with apparatus intended therefor. Aktiebolaget Kvafveindustri. E.P. 141,656, 16.7.19. Conv., 12.4.19.

SEE U.S.P. 1,342,809 of 1920; J., 1920, 550 A.

Electrically-heated crucible, melting-pot, and the like. C. W. Speirs, Assr. to Morgan Crucible Co., Ltd. U.S.P. 1,366,135, 18.1.21. Appl., 2.6.19.

XII.—FATS; OILS; WAXES.

Soya bean oil; Characterisation of —— electrically. G. Dall'Acqua. Giorn. Chim. Ind. Applic., 1920, 1, 48—53.

VARIOUS characters of soya bean, maize, and grapeseed oils are compared. Comparatively small differences are shown by the molecular weights in freezing benzene, or by refractive indices or their temperature coefficients, of the oils themselves or their fatty acids. Discharge of an electroscope of the Elster and Geitel type, however, occupies only a fraction of a second when taking place through soya bean oil and from 15 to 100 seconds with various other oils or their fatty acids; in the case of a very old sample of soya bean oil, which was profoundly changed, 1·6 seconds was required.—T. H. P.

Lemon-seed oil. Bertolo. Giorn. Chim. Ind. Applic., 1920, 1, 54—55.

LEMON-SEEDS occur in large quantities in the so-called *pastazzo*, which forms the residue of the citrus industry. When pressed the material yields little oil, but extraction with carbon bisulphide, petroleum spirit, or benzene gives 30—35% of oil according to the degree of maturation of the seeds. The expressed oil is clear but the extracted oil is turbid and gradually deposits considerable sediment consisting largely of solid, saponifiable substances; the oil retains a pronounced odour of lemons and a somewhat bitter taste; it has a dark yellow colour and a green fluorescence, which is not removed by repeated washing with hot water or dilute sulphuric acid. Its characters are as follows: sp. gr. at 22°, 0·9160 for the expressed, and 0·9180 for the extracted and washed oil; freezing point, −5° to −6°; Zeiss butyrorefractometer reading, 74 at 17° C. and 70 at 25° C.; Maumené value, 78; critical temperature of solution in acetic acid (Valenta test), 108°; oxygen absorbed (Livache's method), 5·4%; m.p. of fatty acids, 41°; solidif. p. of fatty acids, 35°—38° C.; free fatty acids (as oleic acid), 2·82%; saponif. value, 190—191; iodine value, 103—108; Hehner value, 94. The oil is a semi-drying oil. It does not give Halphen's reaction.—T. H. P.

Fatty oils from Reptilia and Amphibia. M. Tsujimoto and S. Kobayashi. Kōgyō Kwagaku Zasshi (J. Chem. Ind. Tokyo), 1920, 23, 1099—1109.

THE paper contains the results of an examination of the oils from certain *Reptilia* and *Amphibia*, viz., blubber oil from "leather turtle," Japanese "Osagame"; oil from "Akaumigame," red turtle, *Caretta olivacea*, Eschholtz; blubber oil and liver oil from "Ishigame," *Clemmys japonica*, Temminck and Schlegel; oil from a Japanese viper, "Mamushi," *Agkistrodon blomhoffii* (Boie); oil from a snake called "Yamakagashi," *Natrix tigrina* (Boie), a harmless species common in Japan; "Aodaisho" oil from *Elaphe climacophora* (Boie), the largest harmless snake found in Japan; python oil from *Python reticulatus*, Schin.; oil from a giant lizard (*Varanus*); toad oil from "Hikigaeru," *Bufo bufo japonicus* (Schlegel); and giant salamander oil from *Megalobatrachus japonicus* (Temm.).—K. K.

Emulsions; Three-phase ——. H. Bechhold, L. Dede, and L. Reiner. Kolloid Zeits., 1921, 28, 6—19.

PAIRS of immiscible liquids such as benzene-water and petroleum-water may be emulsified by shaking with clay, zinc-dust, or yeast. Emulsion formation depends on the quantity of the powder added, the size of the particles, and on the presence of certain other substances termed emulsion promoters. The emulsifying power of the powder (emulsion former) increases to a maximum with decreasing size of the particles and then decreases. Benzene and water are not emulsified by shaking with clay alone, but the addition of a few drops of such substances as pyridine, acetic acid, ethyl alcohol, sodium hydroxide, or sodium nitrate immediately causes emulsification. XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins; Constituents of ——. VII. Lubanyl benzoate from Siamese benzoin. I. A. Zinke and J. Dzrimal. Monatsh., 1920, 41, 423—441.

INVESTIGATION of the chemical transformations undergone by lubanyl benzoate (J., 1915, 681) indicates for this compound the constitution $(4,HO)(3,CH_3)C_6H_3.(1)C_3H_4.O.CO.C_6H_5$. Further, since the benzoate yields eugenol or isoeugenol on reduction, the C_3H_4 residue must represent a direct chain and must contain the double linking; it is possible that this compound is the benzoate corresponding with coniferyl alcohol. (*Cf.* J.C.S., March.)—T. H. P.

PATENTS.

Lamp black; Process for the production of ——. J. M. Gerard and H. J. Masson, jun. U.S.P. 1,364,273, 4.1.21. Appl., 23.12.18. Renewed 29.5.20.

A GASEOUS or vaporised carbon compound is decom-

posed with formation of free carbon by contact with an inert gas at high temperature or by the heat developed in an exothermic gas reaction. The reaction products are rapidly removed from the heated zone in order to ensure a deep black colour in the carbon; further reaction is prevented by spraying with water, whilst the temperature is maintained above 100° C., and the carbon is collected by electrical precipitation.—D. F. T.

Resins; Production of —— *[from naphtha]*. S. P. Miller and F. H. Rhodes, Assrs. to The Barrett Co. U.S.P. 1,365,423, 11.1.21. Appl., 28.8.19.

The solution of polymerised substances obtained in the production of resins from the polymerisable constituents of naphtha is washed with a solution of an acid before the succeeding operations.—D. F. T.

Patents.

Vulcanisation of natural or artificial rubber or rubber-like substances; Process of ——. C. R. de Long and W. N. Watson. U.S.P. 1,364,732, 4.1.21. Appl., 20.7.20.

Dichloroaniline is introduced into the rubber mixture prior to vulcanisation.—D. F. T.

(A) *Sulphur-terpene compound*. (B) *Waterproofed fabric*. (C) *Vulcanised article and process of producing the same*. (D) *Article and process of bonding metal and vulcanised rubber*. W. B. Pratt, Assr. to E. H. Clapp Rubber Co. U.S.P. 1,349,909—12, 17.8.20. Appl., (A) 3.10.19, (B) 8.1.19, (C) (D) 5.5.20. (B) Renewed 3.5.20.

(A) Turpentine oil and sulphur are heated together above 150° C. at atmospheric pressure, whereby hydrogen sulphide is evolved and a product containing 30—50% S is obtained as a thick viscous liquid or a black solid, suitable for use in rubber mixings. A solution of the solid product in toluene or xylene may be used for impregnating cotton or the like. (B) Fabric impregnated with a sulphur-terpene compound (*cf.* A) is used for the manufacture of rubber-proofed goods. (C) Fibrous material in strip or sheet form is treated with the sulphur-terpene compound, then coated with a rubber composition and vulcanised. (D) Metal is coated with the suphur-terpene compound, a layer of vulcanised rubber is then applied, and the whole is subjected to heat and pressure.

Tyre filler. F. A. Hager. E.P. 140,781, 23.3.20. Conv., 11.4.18.

A mixture of soya bean oil (24 lb.), magnesium oxide ($17\frac{1}{2}$ oz.), Venetian red (3 oz.), and sulphur chloride (6 lb.) is poured into moulds. After solidification it is introduced into the cover of a pneumatic tyre in place of the usual tube of compressed air. —D. F. T.

XV.—LEATHER; BONE; HORN; GLUE.

Pelt; Swelling of ——. G. Grasser. Collegium, 1920, 353—359, 405—416, 456—464, 512—518.

Different organic acids behave similarly in regard to their action on pelt swelling; the maximum swelling is only attained after some hours, and the optimum concentration is different for different acids. Monochloroacetic acid gives a maximum swelling with the lowest concentration, then follow oxalic, lactic, formic, and acetic acids. The order of increasing times of attaining maximum swelling is:—Oxalic, lactic, acetic, monochloroacetic, formic acid. The greatest swelling in unit time and per unit concentration is given by monochloroacetic acid, and comparison of the dissociation constants shows no apparent connexion between these and the swelling in unit time and per unit concentration. The velocity of swelling is not influenced by the dissociation of the acids. The influence of salts on swelling is not very definite. Sulphates repress swelling very rapidly; the action of nitrates is more gradual, but ultimately is greater than that of sulphates at the highest concentrations. Dissociation does not explain the repressing effects of salts. This repression is not proportional to the concentration of the salt solutions used, hence it is not a purely osmotic effect. Cuttings of pelt treated with dilute hydrochloric acid solutions with varying additions of sugar solution showed increased swelling and acid adsorption with increased addition of sugar. The sugar did not repress the swelling, confirming the view that the effect of neutral salts on swollen pelt is not an osmotic process. The amount of organic acids absorbed was fairly constant and remained uninfluenced by the addition of salts; it was about 1·15 c.c. of $N/1$ acid for 2 g. of pelt. This result indicates that the absorption is a chemical process with the formation of salts of hide substance. The average water content of pelt being 58%, 100 g. of dry hide substance requires 5 g. of hydrochloric acid, which agrees with the formula $C_{55}H_{87}O_{13}N_{11},HCl$ for collagen hydrochloride and indicates a free amino-group in collagen.—D. W.

Synthetic tannins; Tanning and chemical properties of the sulphonic groups in ——. W. Moeller. Collegium, 1920, 520—536.

Strong solutions of synthetic tannins attack hide substance and leather. Dilute solutions, therefore, should be used, and careful after-treatment is necessary to obviate subsequent deterioration. Vegetable tannins, phenol, and gallotannic acid do not attack the hide substance, hence in vegetable tanning the hydrolysis ceases. Tannins may be defined as substances which, either alone or in contact with hide substance, form colloidal solutions, which prevent decomposition of the hide by hydrolysis and fermentation and are irreversibly adsorbed by it. Vegetable tannins diminish the "proteolytic constant," *i.e.*, the quantity of hide substance dissolved as a result of hydrolysis; Neradol D and ND, Ordoval G and 2 G increase it. The addition of 50% of vegetable tannin to synthetic tannin reduces the extent to which the "proteolytic constant" is increased. Sulphuric acid does not increase the constant much, but β-naphthalenesulphonic acid increases it considerably. The acidity of synthetic tannins diminishes after they have been in contact with hide powder. The free sulphonic acids in the synthetic tannins split up the micellar bands of the hide fibrils into free micells, which are subsequently broken up into protein molecules, and these are further hydrolysed to amino-acids, which combine with the sulphonic acids to form soluble condensation products; hence the diminished yield of leather with even moderate use of synthetic tannin. The use of more synthetic tannin does not result in increased

weight, and leather tanned with it should be well washed to remove excess tannin. Defects arising in leathers tanned with synthetic tannins are not due to free sulphuric acid, but to the sulphonic acids, which are more reactive, causing brittleness and deterioration. Only a very small portion of synthetic tannin acts as true tannin. Similar effects can be obtained by adding free mineral acid or any sulphonic acid to a vegetable tanning material. Synthetic tannins appear to be related to bates, and where a loose leather is not a disadvantage the bating could be shortened and synthetic tannins employed in the tanning process to carry on the bating simultaneously with the tanning.—D. W.

Basicity of chrome [tanning] liquors; Form of expression for the ——. K. Schorlemmer. Collégium, 1920, 536—538.

The usual chrome liquor analysis gives the percentage of Cr_2O_3 (*a*) and of SO_4 in the sample. The SO_4 is calculated in terms of Cr_2O_3 (*b*), and $100b/a$ gives the percentage of Cr_2O_3 combined with its full equivalent of acid. The percentage of chromium combined with hydroxyl groups is obtained by deducting this figure from 100, and the resulting figure is an expression of the basicity. The following are the basicities obtained: $Cr_2(SO_4)_3$, 0; $Cr(OH)SO_4$, 33·3%; $Cr_2(OH)_4Cl_2$, 50·0%; $Cr(OH)_3$, 100·0%.—D. W.

Patents.

Patent leather; Process for drying (hardening) ——. C. Heyl. G.P. 327,794, 19.9.15.

The material is dried in an oven through which a current of dry, warm air passes. The air may be dried by cooling. Moist air hardens the leather in an unsatisfactory manner, and the defect cannot be rectified in the subsequent hardening process. —A. J. H.

Patent leather; Process for drying —— under the influence of ultra-violet light. C. Heyl. G.P. 328,241, 24.10.19. Addn. to 303,096.

The leather is dried under the influence of ultraviolet light in an atmosphere of indifferent gases (nitrogen, carbon dioxide, or gaseous products of combustion) containing not more than 2% by vol. of oxygen (10% of air). The temperature is preferably below 50° C. and the air is as dry as possible. Under these conditions, the amount of ozone formed is negligible.—A. J. H.

Leather; Manufacture of ——. J. Reerink. G.P. 328,240, 26.9.18.

After treatment with sodium thiosulphate, raw hides are treated with dilute sulphite-cellulose liquors to which may be added water-soluble "tanning oils." The hides are then tanned and prepared in the usual manner, whereby a supple and highly durable leather is obtained.—A. J. H.

Catgut; Manufacture of ——. C. Braun. G.P. 327,402, 7.8.17.

The separated intestines are treated, either before or during disinfection, with dilute acids or with solutions of acid salts or salts which have an acid reaction when dissolved in water.—A. J. H.

Glue, gelatin and the like; Apparatus for the extraction of ——. F. H. Tunnell. U.S.P. 1,364,904, 11.1.21. Appl., 28.6.19.

An extracting liquid in intimate contact with the glue-yielding material is locally heated so as to set up circulation, whereby the liquid is raised to a point above the said material, diffuses over its surface, percolates through it, and returns to the starting point.—D. W.

Leather; Process for making —— with the assistance of iron salts. O. Röhm. U.S.P. 1,364,316—7, 4.1.21. Appl., 10.3.17. Renewed 28.5.20.

See E.P. 103,827 of 1917; J., 1918, 14 A.

XVI.—SOILS; FERTILISERS.

Soil solution; Relation of the —— to the soil extract. D. R. Hoagland, J. C. Martin, and G. R. Stewart. J. Agric. Res., 1920, **20**, 381—395. (*Cf.* Hoagland, J., 1918, 252 A.)

Further evidence is given showing that water extracts reflect the principal fluctuations taking place in the soil solution due to season and crop growths as indicated by the freezing-point method. Soil extracts were prepared using 1 pt. of soil to ½ or 1 pt. of water, which, when concentrated so that they showed the same freezing-point depression as the moist soil, did not alter appreciably in concentration or composition on contact with the soil. It is probable that the ratios between most of the important elements or ions are very similar in concentrated soil extracts and in the soil solution. Suitable soil extracts may be made by extracting 1 pt. of soil with 1 pt. of water, or at the most 5 pts. of water, the time of contact being limited to that necessary for thorough admixture. Analysis of such extracts and determination of freezing-point depressions would probably permit of a determination of the concentration and approximate composition of the soil solution. (*Cf.* J.C.S., March.)—W. G.

Soil; Effect of season and crop growth on the physical state of the ——. D. R. Hoagland and J. C. Martin. J. Agric. Res., 1920, **20**, 397—404.

The physical state of certain soil constituents is influenced to a marked degree by the concentration of the soil solution. There is a considerable seasonal variation in the colloidal state of the soil, as determined by turbidity measurements, and a large increase in colloidal matter is noted when the soil solution is depleted as a result of absorption of solutes by the plant.—W. G.

Azotobacter; Influence of luminous radiations on ——. E. Kayser. Comptes rend., 1921, **172**, 183—185.

A comparison of the influence of light of different colours on the third and sixth generations of *Azotobacter* as regards their nitrogen-fixing power. (*Cf.* J.C.S., March.)—W. G.

Basic slag; Improvement of low-grade ——. W. S. Jones. Trans. Faraday Soc., 1920, **16**, 324—327.

Basic slag may be improved in quality by washing on a concentrating table and subsequently drying; in this way the phosphate content may be increased about 12%. By suitable tapping of the furnace, the slag may be separated into a richer and a poorer slag. Direct enrichment may be obtained by adding rock phosphate to the slag either in its molten condition or when cold before grinding. Frequently a low-grade slag is returned to the blast furnace with the next charge and its phosphorus taken up by the pig iron, from which it is obtained again in the Bessemer converter in the form of an enriched slag. The suggestion is made that the principle of the Bertrand-Thiel process might be utilised. In this process two furnaces are used, the pig iron being melted in the first without scrap before being run into the second containing the scrap etc. As no scrap is used in the primary furnace, the slag is not diluted thereby, and a grade containing a high percentage of phosphorus can be obtained.—J. H. J.

Basic slags; Solubility of ——. *Part I. The reason why fluorspar in basic slag makes it relatively insoluble.* F. Bainbridge. *Part II. Solubility of basic slag in citric acid and carbon dioxide solvent.* J. E. Stead and E. W. Jackson. Trans. Faraday Soc., 1920, **16**, 302—309.

I. Increasing amounts of fluorspar were added to a soluble slag and the solution curve determined. The solubility of the slag decreased rapidly and at a ratio of 8 calcium fluoride to 100 tricalcium phosphate became constant. A similar effect was produced in mixtures of calcium phosphate and silicate. In this case it is probable that a new compound consisting of lime, phosphoric acid, and calcium fluoride is formed. An open-hearth furnace slag was made with the addition of calcium fluoride and allowed to cool slowly. The interior of the mass consisted of needle-shaped crystals which upon analysis and crystallographic examination were found to be artificial apatite with some excess of fluoride and silicate. A solubility test on 5 g. of the crystals showed that 5% of the phosphate was soluble, and on 1 g. 26% (*cf. infra*). II. Four samples, namely, a soluble slag, an insoluble slag containing much fluorspar, a partly soluble slag containing little fluorspar, and artificial apatite crystals, were compared as to the solubility of their phosphate by the ordinary citric acid test and by repeated extraction with a saturated solution of carbon dioxide. It was found that, except in the partly soluble slag, long continued attack by carbonic acid dissolved out as much or more phosphoric acid than a single attack by citric acid, and that the solubility in either solvent was of the same order.—J. H. J.

Basic slags; Comparison of the effect of various types of open-hearth —— *on grassland.* G. S. Robertson. Trans. Faraday Soc., 1920, **16**, 291—301.

Field experiments were made on three different soils under grass which were deficient in phosphate. Three varieties of basic slag were used: a high-grade Bessemer slag with 92% of soluble phosphate (on total phosphate), low-grade basic slags with 80—93% of soluble phosphate, and open-hearth basic slags with 20—45% of soluble phosphate. The hay crop was found to be as heavy on land treated with an open-hearth slag of 45% soluble phosphate as on land treated with the high-grade slags, but open-hearth slags with soluble phosphate below this amount gave much lighter crops. Clover crops were much increased by the application of open-hearth slag of 20% soluble phosphate, though the results were inferior to those with 90% soluble slags. A test of the citric solubility of the slags was made, using 1 g. of the sample instead of the usual 5 g. As a result, the citric solubility of the open-hearth slags was increased to over 60%, whilst the other basic slags showed 90—100% solubility. A Gafsa rock phosphate showed an increase from 38 to 89% solubility under the same conditions. In order to enable open-hearth basic slags of 5—8% phosphate content to be utilised as fertilisers it is suggested that they should be enriched during the process of manufacture by the addition of rock phosphate to the molten slag in the ladle.—J. H. J.

Chloropicrin; Action of —— *on the germination of seeds.* E. Miège. Comptes rend., 1921, **172**, 170—173.

Chloropicrin at a concentration of 20 c.c. per cb. m. of space is capable of destroying parasitic insects on seeds such as peas, beans, and wheat after 24 hrs.' contact. Its action on the germination of the seeds varies with the species of seed. At this concentration it has very little effect on the germination of leguminous seeds or linseed, but in other cases it markedly reduces the germinative capacity and rate of germination of cereal, beetroot, and hemp seeds. This effect increases with the concentration of the chloropicrin and the duration of contact, and under the conditions requisite for disinfection it reduces the germinative capacity of wheat by 30%.—W. G.

Seed wheat; Injury to —— *resulting from drying after disinfection with formaldehyde.* A. M. Hurd. J. Agric. Res., 1920, **20**, 209—244.

Seed wheat which has been disinfected by treatment with 0·1% formaldehyde solution and kept in dry storage suffers considerable injury, but this injury can be prevented by sowing the seeds immediately after treatment. Experiments have now shown that the injury can be entirely prevented if the seeds are kept damp or are washed before being dried. As formaldehyde can be detected in seeds which have been dried, it is evident that the aldehyde remains on the seed as paraformaldehyde which gives off formaldehyde gas slowly in intimate contact with the seed. If the seed is stored in presence of an atmosphere of over 70% humidity, it is not injured, and in an absolutely dry atmosphere also there is no injury, but in intermediate humidities injury occurs. Formaldehyde solutions evaporated in moist atmospheres give no paraformaldehyde when the humidity is over 70%, but paraformaldehyde is found in increasing amounts in humidities below 60%. Untreated wheat is entirely killed in presence of strong formaldehyde solution in atmospheres of humidities over 30%. Apparently formaldehyde does not enter the seed as a solid nor as a gas, but in the state of solution. For seed injury to take place during dry storage sufficient moisture must be present to permit of paraformaldehyde being formed and of formaldehyde solution entering the seed. Barley is less susceptible than wheat, and the sorghums are quite uninjured even if 0·2% solution is used.—J. H. J.

Sulphur dioxide; Prevention of damage to vegetation by absorbing —— *by charcoal.* Technischer Büro für die Chem. Ind. Chemotechnik, Wiesbaden. Chem.-Zeit., 1921, **45**, 96—97.

The use of wood charcoal for the removal of sulphur dioxide from waste gases is recommended. Whereas water only absorbs 13·5% of its volume of sulphur dioxide from an atmosphere consisting entirely of the gas, and much less from a mixed atmosphere, charcoal absorbs 165 times its volume of the gas even from an atmosphere containing only small quantities of it. The recovery of the gas from the charcoal is also easy.—J. H. J.

XVII.—SUGARS; STARCHES; GUMS.

Beet slices; Dry distillation of exhausted ——. W. Paar and A. Starke. Z. Ver. deuts. Zuckerind., 1920, 445—449.

On dry distilling 200 g. of exhausted beet slices, 29—32 l. of gas (corresponding to 150 cb. m. per 1000 kg.) was obtained. This gas, which contained 16·0% CO, 20·9% CH_4, and 15·4% H_2, burnt with a luminous flame, and formed an explosive mixture with air and oxygen. It is suggested that the formation of gas of similar composition may explain the frequent explosions occurring in beet slice drying plants, local superheating of the product under the conditions obtaining not being unlikely.
—J. P. O.

Beet slices; Occurrence of saponins in exhausted ——. A. Traegel. Z. Ver. deuts. Zuckerind., 1920, 449—459.

Exhausted beet slices after drying were extracted with methyl alcohol, when the presence of neutral and acid saponins was established in the residue

obtained after removing the solvent, which residue was also proved to possess a strong hæmolytic effect. The presence of saponins explains the death of fish in streams into which slice press waste waters have been discharged.—J. P. O.

Beet sugar after-products; Crystallisation in the working of ——. A. Grill. Z. Ver. deuts. Zuckerind., 1920, 459—468.

SINCE the supersaturation of a solution of sucrose increases as the temperature falls, it is often necessary to add a certain quantity of water to the massecuite in the crystallisers while cooling to a suitable temperature for centrifuging, this quantity depending upon the temperature, the purity, and the density of the product concerned. The following table shows the Brix degree which the mother-syrup of a massecuite should possess for crystallisation without addition of water when centrifuging at temperatures between 35° and 60° C.

Apparent purity of syrup.	Temperature of centrifuging.				
	35°	42°	45°	50°	60°
	Bx.	Bx.	Bx.	Bx.	Bx.
57	85·4	87·2	87·5	88·2	90·7
58	85·7	87·5	87·7	88·5	90·9
59	86·0	87·7	88·0	88·7	91·1
60	86·3	88·0	88·3	89·0	91·3
61	86·6	88·3	88·5	89·2	91·5
62	86·9	88·5	88·8	89·5	91·7
63	87·2	88·8	89·0	89·7	91·9
64	87·5	89·1	89·3	90·0	92·1
65	87·8	89·3	89·6	90·2	92·3
66	88·1	89·6	89·8	90·5	92·5
67	88·4	90·0	90·1	90·7	92·7
68	88·7	90·2	90·4	91·0	92·9
69	89·0	90·4	90·7	91·2	93·1
70	89·3	90·7	90·9	91·5	93·3
71	89·7	91·0	91·2	91·8	93·5
72	90·0	91·3	91·5	92·0	93·7
73	90·3	91·6	91·8	92·3	93·9
74	90·6	91·9	92·0	92·5	94·1

When the syrup is so concentrated as to be without the range of values given in the table, the volume to which it must be diluted to bring its density to a suitable value is calculated, and the appropriate amount of water mixed with the contents of the crystallisers, preferably in three or four portions at a time, while continually stirring.—J. P. O.

Vegetable decolorising carbons; Factors governing the decolorising effect of ——. A. B. Bradley. Int. Sugar J., 1921, 23, 25—32.

EXAMINATION of the effect of treating 50% solutions of raw Jamaica sugar with various decolorising carbons of different origin (adding 5% of the weight of syrup) showed that the greatest decolorising effect concurs with the most rapid rate of filtration. Moreover, in the case of 4 of the 5 samples tested (which included "Norit" and "Eponit") it was found that both the decolorising effect and the rate of filtration decreased as the amount of "dust" (that is, carbon passing a 124-mesh sieve) increased. This is true also in factory practice, filtration with fine or disintegrated carbon being much slower than with more uniformly coarse material, probably owing to the colloidal impurities forming a semi-pervious layer with the finer grains. Carbons having the greatest volume per unit weight give the best result in respect both of decolorising effect and rate of filtration; but equal volumes of different samples of decolorising carbons having the same degree of fineness do not give similar decolorising effects, the efficiency being probably influenced by the porosity of the material. When samples of decolorising carbons were treated successively with four portions of raw sugar liquor (without revivification at each stage), the samples containing the highest amount of "dust" were the most readily exhausted, and those which contained the maximum quantity of medium grain (that is, between 84- and 106-mesh) maintained their efficiency best.—J. P. O.

Sugar mixtures containing two monosaccharides; Analysis of ——. C. A. Browne. Int. Sugar J., 1921, 23, 35—38.

VAN DER HAAR ("Anleitung zum Nachweis, zur Trennung, und Bestimmung der Monosaccharide," p. 133) has criticised the general principle of the author's method for analysing mixtures containing two reducing sugars (J., 1906, 446) on the ground that the reduction ratios of the sugars are not constant. It is, however, pointed out that in determining the reduction ratios Van der Haar averaged the extreme values indicating the reducing power of the various sugars, whereas the ratios taken at frequent regular intervals should have been averaged. On re-calculating the reduction ratios obtained by Van der Haar when using Schoorl's method, the figures found were in good agreement with those originally stated by the author (*loc. cit.*) when applying Allihn's method, and also with those found by Kjeldahl's procedure. It is concluded that the employment of reduction ratios in the analysis of sugar mixtures containing two monosaccharides is reliable for any of the ordinary methods of copper reduction with Fehling's solution; and that the ratios established for one method of reduction are applicable without serious error to other methods of reduction.—J. P. O.

Sucrose; Experiments on the inversion constant of pure —— *in following the Clerget-Herzfeld double polarisation procedure.* O. Schrefeld. Z. Ver. deuts. Zuckerind., 1920, 402—408.

EXPERIMENTS carried out in 1910 showed that the factor for the calculation of the % sucrose in the Herzfeld modification of the double polarisation method should be about 133·0 at 20° C. when the temperature of hydrolysis is 60° C., the concentration 15 g. in 100 c.c., and the duration of heating 10—15 mins. (*cf.* Jackson and Gillis, J., 1920, 634 A.) —J. P. O.

Invert sugar in a partially inverted and concentrated solution of sucrose; Tables for the approximate calculation of the ——. W. Paar. Z. Ver. deuts. Zuckerind., 1920, 409—413.

GIVEN the quotient of purity, Q, of the syrup before inversion, the Brix degree, B, after inversion and concentration, and the polarisation, P, of the syrup also after inversion and concentration, the invert sugar per cent. $I = 0{\cdot}00754(B \times Q - 100\,P)$; or where the total sugar per cent., T, is known, $I = (T - P)\,0{\cdot}754$. Based upon these equations, tables have been constructed for the ready calculation of the invert sugar per cent. in the case of syrup of 90° and 95° quotient of purity, the Brix degree varying from 50° to 80°, and the polarisation from +70° to −20°.—J. P. O.

Calcium salts in sugar juices and syrups; Determination of —— *volumetrically, using standard soap solution.* W. Montgomery. Int. Sugar J., 1921, 23, 39—42.

TABLES are given for the calculation of the calcium oxide as % of total solids (Brix), given the c.c. of soap solution (1 c.c. of which = 0·001 g. CaO), and the Brix of the juice or syrup examined.—J. P. O.

PATENT.

Sugar factories; Manufacture of a precipitate [feeding stuff] rich in albumen and poor in ash from the raw juices and waste liquors of [beet] ——. M. von Wierusz-Kowalski. E.P. 132,798, 16.9.19. Conv., 11.7.16.

THE liquid, heated to 80°—100° C., is treated with

a very small amount (0·01—0·02%) of sulphurous acid, and then, at about 80° C., with sufficient lime or other base to produce an alkalinity of 0·02—0·04%. The precipitate obtained contains about 20% of protein, 5% of phosphoric acid, and 10% or less of ash, and may be employed as a feeding stuff.—J. H. L.

XVIII.—FERMENTATION INDUSTRIES.

Malt; Simplification of the Lintner-Wirth method for determining the diastatic power of ——. G. Roeder. Woch. Brau., 1921, 38, 5—7.

The procedure suggested comprises the same operations as in the Institute of Brewing Committee method (J., 1906, 236), but the malt extract is allowed to act on the starch solution for ½ hr. at 17·5° C. instead of 1 hr. at 70° F. (21° C.), the reducing sugar is determined by Kjeldahl's gravimetric method, and the diastatic power is expressed as g. of maltose per 100 g. of malt.
—J. H. L.

Malts; Determination of the extract of coloured ——. C. G. Matthews. J. Inst. Brew., 1921, 27, 22—25.

The Institute of Brewing Committee method (J., 1910, 1323) has several practical disadvantages, and usually gives somewhat low results. The following has been found more convenient and accurate:—A mixture of 40 g. of standard malt (D.P. 35°—45° Lintner), ground to 25° Seck, and 10 g. of the sample of crystal malt, similarly ground, is mashed by the Committee method, and a bright filtered wort obtained in the usual way. Then (sp. gr. of wort−4/5 sp. gr. of 10% wort from the standard malt)×5=sp. gr. due to sample; and this multiplied by 3·36 gives the extract yield of the sample. Further, (colour of the wort in a 1 in. cell−4/5 colour of 10% wort from the standard malt)×5 =colour of sample in 10% wort; this multiplied by 10 gives the total colour units referred to the sample itself. The method is applicable to all coloured malts and also to flaked materials. Some comparative results with this and the Committee method are given in tables.—J. H. L.

Maize and rice and the method of using them [in brewing]. W. Windisch. Woch. Brau., 1921, 38, 9—15.

In view of the fact that German brewers are now permitted to employ maize grits, free from husks and embryos, and also rice products unsuitable for human consumption, the author gives an account of the composition, method of production, and brewing properties of these adjuncts, and also discusses the manner in which they may be employed in brewing. Some experiments on the malting of maize are also described.—J. H. L.

Cellulose; Action of dilute mineral acids on ——. A. Wohl and K. Blumrich. Z. angew. Chem., 1921, 34, 17—18.

The insoluble residue (hydrocellulose) remaining after prolonged heating of cellulose with dilute acids is of the nature of a reversion product rather than an intermediate degradation product; such residues are often more resistant to hydrolysis than the original cellulose, and unsuitable for fodder owing to their indigestibility. In the hydrolysis of cotton cellulose by 0·5—3% hydrochloric acid at 100° C., the cupric-reducing powers of the residue and the solution were determined at different stages. When, after a certain period of heating, the solution was separated from the residue and both were further heated separately with acid of the same concentration, more total reducing sugar was formed than when the heating was continued without any such separation. It is concluded that reducing sugars which have already passed into solution interact, on continued heating, with the residue in the colloidal phase, and form reversion products.—J. H. L.

Cellulose; Saccharification of ——. A. Wohl and H. Krull. Cellulosechemie, 1921, 2, 1—7.

In laboratory experiments cellulose (cotton) yielded 97% of the theoretical amount of reducing sugar by a preliminary liquefaction (primary hydrolysis) with fuming hydrochloric acid, followed by saccharification (secondary hydrolysis) by boiling with dilute acid. The best method of procedure was as follows: The material was moistened with 3 pts. of water and then cooled by means of ice and saturated with hydrogen chloride. It was then left for 5 hrs., or longer, at 20° C., after which nearly the whole of the acid was removed by evaporation *in vacuo* at temperatures up to 70° C. The residue was dissolved in water and the solution, containing about 10% of material and 1% of hydrochloric acid, was boiled for 8 hrs. The sugar was determined as dextrose by cupric reduction. Results obtained with a variety of products indicate that the method might be employed for the determination of cellulose. 100 g. of pine shavings (dry substance) gave 60·9 g. of apparent dextrose from which 18 g. of alcohol was produced on fermentation. This yield of alcohol is only about 60% of the theoretical, whilst the reducing sugars obtained from pure cellulose gave alcohol equivalent to 90% of the theoretical. Probably the hydrolysis of the cellulose in wood is impeded by incrusting substances, and, on the other hand, if the duration of the primary hydrolysis is prolonged to 24 hrs. non-fermentable reversion products are formed in relatively large quantities (*cf.* preceding abstract). All attempts to improve the process by a preliminary treatment to dissolve the lignin were unsuccessful; the yield of reducing sugars was increased, especially by chlorine treatment, but the yield of alcohol was diminished. An 18% yield of alcohol from pine wood, however, would entitle the process to serious consideration if only the difficulties associated with the evaporation of the hydrochloric acid on a large scale could be overcome.—J. H. L.

Wine; Determination of sugar in ——. W. Fresenius and L. Grünhut. Z. anal. Chem., 1920, 59, 415—457.

A scheme of analysis is proposed, to replace the present German official methods. The main features are as follows:—Samples used for the determination of sugars are de-alcoholised by evaporation to one-third their volume, after neutralisation. The reducing and rotatory powers are in general determined after clarification with basic lead acetate and removal of excess of lead by sodium sulphate; but for dry wines animal charcoal may be employed, to avoid dilution. For the hydrolysis of sucrose the Clerget-Herzfeld procedure is adopted, and before the subsequent clarification with basic lead acetate the hydrochloric acid is precipitated by a slight excess of silver nitrate; an aliquot part of the filtrate from the silver chloride is almost neutralised with sodium hydroxide and then treated with basic lead acetate, the excess of lead and silver being afterwards removed by means of sodium phosphate. Reducing sugars are determined by the gravimetric method, except in dry wines containing less than 5 g. per litre, for which Schoorl's volumetric method (J., 1899, 791) is used. Formulæ based on Woy's equations (Z. öffentl. Chem., 1898, 4, 33) are given for calculating the amounts of dextrose and lævulose present in wine from the reducing and rotatory powers as determined by the methods described.
—J. H. L.

Methyl alcohol; Detection of —— in spirits. F. Rabe. Pharm. Zeit., 1921, 66, 72.

THE formaldehyde resulting from the oxidation of methyl alcohol may be identified by means of morphine-sulphuric acid reagent; in preparing the latter by mixing morphine hydrochloride with sulphuric acid care should be taken to expel all hydrochloric acid by heating the mixture, otherwise a red coloration develops in the reagent itself and renders it useless. Resorcinol-sulphuric acid reagent (0·2 g. per 10 c.c.) is recommended for the detection of formaldehyde.—W. P. S.

Action of dyes on yeast. Fraser. *See* XIXB.

Beer or other fermented liquors; Process of brewing or preserving ——. R. de Fazi. E.P. 143,506, 12.5.20. Conv., 9.10.19.

BEER is treated, after the fermentation, with about 0·01—0·02% of hexamethylenetetramine or derivatives thereof.—J. H. L.

Alcohol; Recovering —— from fermented liquids and apparatus therefor. W. G. Toplis. U.S.P. 1,364,160, 4.1.21. Appl., 27.7.17.

THE waste liquid (distillation residue) from a primary distillation apparatus is subjected to a secondary distillation, and the alcohol obtained from the latter is mixed with the supply of original liquid before this liquid enters the primary distillation apparatus.—J. H. L.

Sulphite-cellulose waste lyes. U.S.P. 1,342,721. *See* V.

XIXA.—FOODS.

Lard; Detection of adulteration of —— with fats containing tristearin. R. H. Kerr. J. Assoc. Off. Agric. Chem., 1920, 4, 195—201.

FIVE g. of the lard is diluted to 25 c.c. with warm acetone in a stoppered cylinder, and the mixture is kept at 30° C. for 18 hrs.; the liquid is then decanted and the mass of crystals at the bottom of the cylinder is washed twice with warm acetone, using 5 c.c. each time and taking care not to break up the deposit. The latter is shaken with a further 5 c.c. of warm acetone, transferred rapidly to a small filter, again washed with acetone, and the excess of the latter removed as far as possible by suction. The crystalline deposit is spread on paper, dried, and the m.p. determined. A m.p. below 63·0° C. indicates adulteration. The fatty acids are then obtained from the crystals in the usual way and their m.p. determined. If the m.p. of the glycerides (crystalline deposit) plus twice the difference between the m.p. of the glycerides and the m.p. of the fatty acids is less than 73° C., the lard is adulterated.—W. P. S.

Histidine [in proteins]; New method for the determination of ——. W. E. Thrun and P. F. Trowbridge. J. Assoc. Off. Agric. Chem., 1920, 4, 194—195.

A BROMINE absorption method is described for use in conjunction with the Van Slyke method (J., 1911, 1135). An aliquot portion of the solution containing the bases of a coagulable protein is treated with bromide-bromate solution and hydrochloric acid, and, after 15 mins., the excess of bromine is titrated with thiosulphate solution. Sulphur is determined in another portion of the solution and the quantity of cystine present is calculated from the sulphur content. One mol. of cystine absorbs 10 atoms of bromine, whilst 1 mol. of histidine absorbs somewhat more than 2 atoms of bromine; consequently a factor for the bromine absorption of histidine is necessary.—W. P. S.

Ammonium citrate; Behaviour of neutral —— in certain phosphate solutions. [Determination of lead in phosphate baking powders.] H. E. Patten and G. H. Mains. J. Assoc. Off. Agric. Chem., 1920, 4, 235—237.

IN the determination of lead in phosphate baking powders the addition of neutral ammonium citrate to the hydrochloric acid solution of the powder prevents the precipitation of calcium phosphate when the solution is treated with ammonia. At p values below 5·0 calcium citrate remains in solution; between 5·0 and 7·0 the precipitation of calcium citrate is very slow, but at 7·1 an immediate permanent precipitate of gelatinous calcium citrate is formed.—W. P. S.

PATENTS.

Foods from kitchen waste and the like; Manufacture of animal ——. R. L. D. Taylor. E.P. 140,812, 26.3.20. Conv., 25.2.19.

KITCHEN waste is sorted, pressed to remove excess water, and mixed with a vegetable filler, such as oat hulls. The mixture is passed through a pulping machine and then down an inclined rotary dryer heated by steam at 352° F. (178° C.), which converts the pulp into nodules. From the dryer the material falls on to a belt conveyor passing through an oven at 400° F. (about 200° C.), which completely cooks and sterilises it. On leaving the oven the material passes through a screening device to separate the nodules of $\frac{1}{8}$—$\frac{3}{16}$ in. diameter, which are suitable to be used as a scratch food for poultry. The coarser and finer nodules are collected separately and ground, and serve as a meal for making into dog biscuit.—J. H. J.

Margarine; Manufacture of ——. J. E. Green, jun. E.P. 156,000, 9.1.20.

HARD fat is placed in a closed jacketed vessel supported on trunnions, and steam is passed through the jacket to melt the fat, which is stirred continually by a gauze mixer in order to collect fibrous material. The mixer is afterwards removed with the adhering fibrous material, and is cleaned and replaced. Cold soured milk and oil are introduced into the vessel and the mixer rapidly rotated until a uniform product is formed. This is cooled by passing a cooling medium through the jacket, and agitation is continued until the whole thickens to a homogeneous emulsion to which salt and preservatives are added, and agitation completed at a high speed.—J. H. J.

Bread-making; Composition of materials adapted for use in ——. Method of manufacturing dough ingredients. Method of producing materials for bread-making and composition of materials for use as a bread-dough ingredient. R. L. Corby, Assr. to The Fleischmann Co. U.S.P. (A) 1,355,127, (B) 1,355,128, and (C) 1,355,129, 12.10.20. Appl., (A) 15.7.15, (B) and (C) 15.6.17. Renewed, (A) 5.2.20, (B) 29.7.20, (C) 30.7.20.

(A) A PRODUCT such as is obtained by the process described under (B). (B) A cereal mash is saccharified, and then acidified (with lactic acid) sufficiently not only to render the diastatic and proteolytic enzymes inactive but also to condition the gluten of the dough; after filtering from undissolved and coagulated matters, the filtrate is evaporated. (C) Invert sugar is mixed with the product before evaporation. —J. H. L.

Butterin, oleo-margarine and the like; Means for making ——. N. D. Nielsen. U.S.P. 1,364,297, 4.1.21. Appl., 18.4.18.

AN emulsifying tank and a crystallisation vessel are

connected by a duct which enters the latter near the bottom and which is provided with a pump so that emulsion from the tank may be forced into the crystallisation vessel. A propeller within the vessel, near the inlet of the duct, enables the emulsion to be maintained in the lower part of the vessel, but permits crystals formed from the particles of the emulsion to rise to the surface. Means are also provided for forcing cold water into the vessel and for maintaining the contents of the latter at a temperature below 40° F. (4° C.).—J. H. L.

Foods and other substances; Apparatus for heat-treating ——. N. H. Fooks. U.S.P. 1,363,103, 21.12.20. Appl., 22.12.19.

A RETORT is provided with inlet and outlet orifices for liquid, means for admitting gas under pressure at a point within the upper part, means for heating, and charging and discharging ports at the top. Within the retort is a rotary spiral conveyor by which objects are carried by a tortuous path from the charging to the discharging port. There are also air-locks at the ports and means for moving the objects through the air-locks.—J. H. L.

Food preparation and process of making same. F. E. Coombs, Assr. to J. F. Judge. U.S.P. 1,363,193, 21.12.20. Appl., 10.10.19.

A COOKED, desiccated starchy food of loose-grained character, the grains of which are superficially free from starch, is prepared by treating the surface of the grains of the cooked material with a diastatic solution, then destroying the diastase by heat, and finally drying and browning the product.—J. H. L.

Chocolate; Process of making soluble ——. J. Friedman. U.S.P. 1,364,192, 4.1.21. Appl., 2.4.19.

A SOLUBLE preparation capable of being moulded and of withstanding a relatively high temperature without softening, is produced by boiling syrup, adding a liquid extract, cooling, powdering the solidified mass, and mixing it with powdered cacao beans and fat.—J. H. L.

Casein precipitate [desiccated milk food]; Desiccated ——. P. W. Turney. U.S.P. 1,364,417, 4.1.21. Appl., 19.4.18.

MILK is curdled by an enzyme to such a degree that a flocculent precipitate is produced, the activity of the enzyme is then arrested by cooling, the product is sprayed into a chamber maintained at a low temperature and under partial vacuum, and dehydrated by means of air currents.

Desiccating [milk]; Process and apparatus for ——. I. S. Merrell, Assr. to Merrell-Soule Co. U.S.P. 1,365,055, 11.1.21. Appl., 30.10.16.

MILK is caused to flow spirally down the interior surface of a heated cylinder, and an elevating force is exerted upon the liquid to retard its flow.
—L. A. C.

Rice; Process for treating ——, *and product thereof.* M. M. Baumgartner. U.S.P. 1,364,912, 11.1.21. Appl., 11.8.19.

HULLED rice grains are steamed under such conditions as to sterilise them and dextrinise their starchy contents without cracking them; they are then dried so as to resemble untreated rice in form, bulk, and moisture-content.—J. H. L.

Coffee; Method of making soluble ——. H. Anhaltzer. U.S.P. 1,365,443, 11.1.21. Appl., 9.11.18.

A SOLID coffee preparation is produced by steaming roasted ground coffee beans, then extracting with alcohol, and finally distilling the extract. All these operations are carried out with exclusion of air, in order to prevent loss of volatile oils.—J. H. L.

Food enclosed in sealed cans and other containers; Process of heat-treating bodies, such as ——. N. H. Fooks. E.P. 156,994, 22.1.20.

XIXB.—WATER PURIFICATION; SANITATION.

Waters; Determination of hydrogen sulphide in natural ——. *Sensitiveness of the starch iodine reaction.* E. Chrétien and H. Vandenberghe. Ann. Chim. Analyt., 1921, 3, 19—23.

ONE litre of the water is treated with 20 c.c. of saturated barium chloride solution, filtered, and 510 c.c. of the filtrate is added to a mixture of 10 c.c. of $N/100$ iodine solution and 0·1 g. of potassium iodide; 10 c.c. of $N/100$ thiosulphate solution is then added and the excess of this is titrated with $N/100$ iodine solution. With 500 c.c. of distilled water free from ammonia and nitrous acid, 0·05 g. of potassium iodide free from iodate, and 1 c.c. of 1% starch paste, a distinct blue colour is produced with 0·10 c.c. of $N/100$ iodine at 10° C., whereas at 19° and 28° C., respectively 0·15 and 0·25 c.c. are required and the coloration is less distinct.
—W. P. S.

Mercuric chloride; Toxicity of —— *and its solubility in aqueous alcohol.* J. S. Laird. J. Phys. Chem., 1920, 24, 736—737.

THE solubility of mercuric chloride in aqueous alcohol shows a pronounced minimum at a concentration of 24% of alcohol and this corresponds closely to the maximum toxicity of such solutions as observed by Paul and Krönig (Z. physik. Chem., 1896, 21, 448).—W. G.

Phenol solutions containing sodium benzoate; Toxicity towards Staphylococcus of dilute ——. K. E. Burgess. J. Phys. Chem., 1920, 24, 738—740.

DETERMINATIONS of the rate at which staphylococci are poisoned by dilute solutions of phenol with and without the addition of sodium benzoate confirm the conclusion that the abnormalities observed by Lemon (*cf.* J., 1920, 799 A) were due to plasmolysis.
—W. G.

Yeast; Action of Methylene Blue and certain other dyes on living and dead ——. C. G. Fraser. J. Phys. Chem., 1920, 24, 741—748.

THE behaviour of nine different dyes, namely, Grübler's Methylene Blue, Fuchsin, Congo Red, Erythrosin, water-soluble Safranine, Merck's Methylene Blue, Gentian Violet, Methyl Green, and Kahlbaum's Methylene Blue 6 B extra, with living yeast and with yeast killed either by boiling or by the action of phenol, was examined in order to find a convenient criterion of death in quantitative toxicological investigations with microbes. Erythrosin and Methylene Blue 6 B extra gave the best results. In a solution of extract of malt to which Methyl Green has been added, yeast cells may lose their power of reproduction without becoming stained.—W. G.

Bacteria; Method for investigating the action of ultra-violet rays on ——. T. Mashimo. Mem. Coll. Sci. Kyoto, 1919, 4, 1—11.

A thin layer of agar culture medium spread over a glass plate and uniformly inoculated with the bacteria under investigation, was exposed to the ultra-violet spectrum in a quartz spectrograph, and afterwards incubated. The parts sterilised by the rays became easily distinguishable from the rest of the plate by the absence of bacterial growth, and the spectral image thus obtained was fixed by exposure to formaldehyde vapour. For all the well-known species of non-pathogenic bacteria investigated, the bactericidal portion of the spectrum was the same, *viz.*, from 295 $\mu\mu$ to 186 $\mu\mu$, the region of greatest activity being about 275 $\mu\mu$.—J. PATENTS.

Filtering apparatus [for water]. W. Paterson. E.P. 156,270, 2.3.18.

In order that each filter in a battery of filters may receive water in proper proportion to its filtering area, it is provided at one side of the space above the filtering medium with a pocket into which the incoming water or precipitation tank effluent falls, passing over a weir as it does so, and from which it flows away into the filter through an opening in the bottom. The overflow from the bottom of the filter is controlled by a valve floating in the liquid over the filter medium. As the level of the water over the medium rises, the float valve opens the outlet until the outflow and the inflow are the same. This continues until the filter begins to become choked, when the valve opens further. Thus the water level gradually rises over the medium until it is flush with the weir in the pocket. In order to prevent splashing in the pocket, the opening between the pocket and the filter may be controlled by a float valve in the pocket which keeps the level of the water just below the weir.—J. H. J.

Sand-filters. N. McK. Barron. E.P. 156,424, 1.10.19.

In a battery of sand filters, the filters are arranged circumferentially around a sand pit, and clogged sand from the filters is passed by means of a pressure ejector into the pit, from which it is lifted and washed in a combined operation by means of a counterflow of water. The washed sand is delivered into a container situated at a level above the top of the filters, and is distributed to the filters as required. The sand container is of such a size as to hold sufficient sand to fill one of the filters and to leave a reserve supply in addition. The container has a tubular extension in its lower portion, the sand in which remains undisturbed when clean sand is delivered into the container; the pipe connecting the container with a filter proceeds from this extension.—J. H. J.

Ozone water-purifying apparatus. H. B. Hartman, Assr. to Electric Water Sterilizer and Ozone Co. U.S.P. 1,363,589, 28.12.20. Appl., 24.1.20.

An apparatus for purifying water by means of ozone includes a storage reservoir, an ozone generator, and automatic means for synchronously controlling the flow of raw water and ozone to the reservoir. —J. H. J.

Sewage; Method of and apparatus for treating ——. C. P. Landreth. U.S.P. 1,364,387, 4.1.21. Appl., 11.1.17.

Sewage is aerated and a precipitant is added; the precipitate is allowed to settle, and the sludge is withdrawn, mixed with suitable finely divided material, and de-watered.— J. H. J.

Sewage; Method of treating ——. J. P. Ball. U.S.P. 1,364,676, 4.1.21. Appl., 22.10.18.

Sewage sludge is subjected to a forced current of air to remove noxious gases, which are passed through a collecting medium to remove the entrained particles of liquid.—J. H. J.

Germicide. C. A. Weeks; L. H. Weeks extrix. U.S.P. 1,366,106, 18.1.21. Appl., 15.6.18.

See E.P. 134,880 of 1918; J., 1920, 80 A.

Composition for liberating sulphur dioxide. U.S.P. 1,356,029—30. *See* VII.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Truxillic and truxinic acids; Natural and synthetic ——. R. Stoermer and E. Laage. Ber., 1921, 54, 77—85.

The isolation of a seventh isomeride of truxillic acid, neotruxinic acid, induces the authors, for the sake of simplicity, to designate only those acids derived from the formula—

$$\begin{array}{c} C_6H_5.CH.CH.CO_2H \\ CO_2H.\dot{C}H.\dot{C}H.C_6H_5 \end{array}$$

as truxillic acids, whilst those derived from the formula—

$$\begin{array}{c} C_6H_5.CH.CH.CO_2H \\ C_6H_5.\dot{C}H.\dot{C}H.CO_2H \end{array}$$

are termed truxinic acids. The truxinic acids can be conveniently separated from the truxillic acids by taking advantage of the fact that the potassium and ammonium salts of the former are very sparingly soluble in cold alcohol, in which the truxillates dissolve freely. The natural mixture of truxillic acids obtained during the isolation of cocaine yields under the most favourable conditions α-truxillic acid (25%), ϵ-truxillic acid (4·25%), β-truxinic acid (29%), δ-truxinic acid (10%), neo-truxinic acid (0·12%); the remainder consists of benzoic and cinnamic acids mixed with considerable quantities of resinous acids. The presence of γ-truxillic or ζ-truxinic acid could not be established. (*Cf.* J.C.S. March.)—H. W.

Fumaric acid and inositol; Occurrence of ——. L. Zechmeister and P. Szécsi. Ber., 1921, 54, 171—173.

Fumaric acid in the form of the acid potassium salt, $2KC_4H_3O_4,H_4C_4O_4$, has been isolated from the alcoholic extract of *Capsella bursa pastoris*. *r*-Inositol, m.p. 218°—219° C., has been obtained from the aqueous extract; it is present to the extent of at least 0·03% of the dried drug.—H. W.

Hydrogenation of aromatic compounds by the help of platinum. IV. Dependence of catalytic hydrogenation on the presence of oxygen. R. Willstätter and E. Waldschmidt-Leitz. Ber., 1921, 54, 113—138.

Catalytic hydrogenation cannot be effected by spongy or colloidal platinum or palladium or by nickel in the complete absence of oxygen; the metals can be activated by agitating their suspensions with air. The active catalysts contain both hydrogen and oxygen, the latter of which is gradually removed during the course of hydrogenation under normal conditions, and rapidly by certain contact

poisons such as glycerol and thiophen, although it remains doubtful if all cases of poisoning are due to this cause. The technique of catalytic hydrogenation can be considerably improved since the catalyst, when showing signs of diminished activity, can be reactivated by treatment with oxygen, and poisoning may be circumvented either by the same procedure or by increasing the amount of catalyst; priming with oxygen is particularly useful when the metal is used repeatedly or in small quantity. The use of spongy palladium has no advantage over that of platinum, whilst, on the other hand, its greater absorptive capacity for hydrogen renders re-activation by oxygen more difficult to such an extent that the process becomes either dangerous or tedious. (*Cf.* J.C.S., Mar.)—H. W.

Chloroacetic acids; Catalytic decomposition of ——. J. B. Senderens. Comptes rend., 1921, **172**, 155—158.

With thorium oxide or kaolin as catalyst, monochloroacetic acid is decomposed at 220° C., giving hydrogen chloride, carbon monoxide and dioxide, and carbon. Trichloroacetic acid gives chloroform, tetrachloroethylene, hexachloroethane, hydrogen chloride, carbon monoxide and dioxide. With animal charcoal as catalyst monochloroacetic acid decomposes as above, but in the case of trichloroacetic acid almost the only change is the formation of chloroform and carbon dioxide. (*Cf.* J.C.S., March.)—W. G.

Propenol [allyl alcohol]; Mode of pyrogenic decomposition, at high temperature, of ——. E. Peytral. Bull. Soc. Chim., 1921, **29**, 39—44.

In the sudden decomposition of propenol at high temperatures the two primary reactions are $CH_2:CH.CH_2OH = CH_2:CH.CHO + H_2$, and $CH_2:CH.CH_2OH = CH_2:C:CH_2 + H_2O$. For every three molecules of propenol decomposed, two yield acrolein and one gives propylene. The acrolein undergoes a secondary change, giving ethylene and carbon monoxide.—W. G.

Formic acid; Sudden pyrogenic decomposition of —— and the preparation of carbon monoxide. J. A. Muller and E. Peytral. Bull. Soc. Chim., 1921, **29**, 34—39.

When formic acid is suddenly decomposed by passing it rapidly through a platinum tube at 1150° C., the primary action is the formation of carbon dioxide and hydrogen. The production of carbon monoxide and water is due to the reduction of the carbon dioxide by the hydrogen. At a sufficiently high pressure the velocity of this secondary reaction may become so great as to make it appear as if it were the primary reaction.—W. G.

Eucalyptol; o-Cresol method for the determination of ——. C. T. Bennett and M. S. Salamon. Perf. Essent. Oil Rec., 1921, **12**, 11—12. (*Cf.* J., 1920, 832 A.)

After further experience the authors modify their criticism of the method (J., 1920, 704 A) and agree with Cocking that it affords a rapid and easy means of determining eucalyptol in all grades of eucalyptus oil provided that they contain not less than 45% of this constituent.—W. P. S.

Acetic acid; Binary and ternary mixtures obtained in the synthetic manufacture of ——. P. Pascal, Dupuy, Ero, and Garnier. Bull. Soc. Chim., 1921, **29**, 9—21.

The two processes of manufacture considered are the direct oxidation of acetaldehyde mixed with acetic acid and the electrolytic oxidation of acetaldehyde or of paraldehyde in sulphuric acid solution. The densities and boiling-points of binary mixtures of water and acetic acid; water and acetaldehyde; and acetaldehyde and acetic acid, and of ternary mixtures of acetaldehyde, acetic acid, and water are given, and alongside the boiling-points of the various mixtures the composition of the liquid and of the vapour is given in each case. The boiling-points of ternary mixtures of acetic acid, sulphuric acid, and water and the composition of the liquid and vapour in each case are also given.—W. G.

Menthone; Electrolytic reduction of ——. M. Matsui and S. Shimizu. Mem. Coll. Sci., Kyoto, 1920, **4**, 245—264.

Menthone can be reduced electrolytically to menthol in acid solution (sulphuric or hydrochloric). The best results were obtained using an amalgamated tin or lead cathode, the cathode solution consisting of a mixture of 75% sulphuric acid (40—45 c.c.) with 94% alcohol (35—40 c.c.) at a temperature below 15° C. The current used was 6—8 ampères per 100 sq. cm. at 11—13 volts. The yield of menthol was only 25% of the theoretical and the product was difficult to purify. An oily by-product was always obtained, especially when more dilute acid was used. This substance is a more highly reduced product and may be menthane. —E. H. R.

Lemon-seed oil. Bertolo. *See* XII.

Saponins in beet. Traegel. *See* XVII.

Patents.

Cymene; Manufacture of para- ——. British and Foreign Chemical Producers, Ltd. From Rheinische Kampferfabr. G.m.b.H. E.P. 156,329, 6.10.19. Addn. to 142,738 (J., 1920, 501 A).

The terpenes of b.p. about 160° C. present in pine-needle oil are treated as described in the chief patent. The yield of p-cymene is increased if the terpenes are heated with an inorganic or organic acid or acid salt, and, after separation from the acid, purified by fractional distillation, using the fraction of b.p. 175° C. for subsequent treatment. —L. A. C.

Reactive acid liquor from hydrocarbon gases containing olefines; Process of making ——. (B) *Acid liquor and process of producing same.* (C) *Process of treating gasoline and the like.* (D) *Separation process of making alcohols.* (E) *Process of purifying alcoholic material.* (F) *Process of separating alcohols and hydrocarbons.* (G) *Solvent.* (H) *Direct production of ester bodies from unsaturated hydrocarbons.* (I) *Ester bodies from unsaturated hydrocarbons.* (J) *Process of directly esterifying olefines and product thereof.* (K) *Process of making ketone bodies.* (A) M. D. Mann, jun., and R. R. Williams, (B, D & G) C. Ellis, (C) M. D. Mann, jun., (E) M. J. and G. Cohen, A. Breslauer and H. Asher, (F, H, I, and J) C. Ellis and M. J. Cohen, (K) C. Ellis and A. A. Wells, Assrs. to S. B. Hunt. U.S.P. 1,365,043–53, 11.1.21. Appl., (A) 11.3.19, (B) 26.6.17, (C) 6.7.18, (D) 5.6.18, (E) 8.6.18, (F and I) 25.4.18, (G) 8.1.18, (H) 25.6.17, (J) 30.6.16, and (K) 18.3.18.

(A) The gases are brought into intimate contact with sulphuric acid in the presence of an inactive absorbent for the gases. (B) Hydrocarbon material containing olefines and liquid saturated hydrocarbons is treated with sulphuric acid, and the product is used for treating more olefine material to obtain an acid liquor saturated with olefines. (C) Sulphuric acid is gradually brought into contact below 20° C. with an intimate mixture of unsaturated hydrocarbons and a large proportion of a diluent for the acid. (D) A mixture of alcohols and sulphuric acid is treated with a material which

dissolves the alcohols but not the acid. (E) Alcohols are purified by distillation in the presence of a small quantity of sulphuric acid. (F) A mixture of alcohols and hydrocarbons is treated with sulphuric acid of the correct strength to dissolve the alcohols. (G) A solvent boiling mainly below 110° C. is composed of a mixture of propyl mono-acetate with small quantities of ethyl and butyl mono-acetate. (H) The product obtained by treating an olefine with sulphuric acid is treated with a substance capable of replacing the sulphuric acid radicle with an organic acid radicle. (I) A liquid material consists mainly of a mixture of unsubstituted mono-esters of monohydric alcohols corresponding to the olefines of cracked petroleum. (J) A fatty acid is heated with an olefine in the presence of an acid catalyst. (K) Cracked gasoline containing unsaturated hydrocarbons is treated with sulphuric acid of sp. gr. 1·8, residual gasoline is separated by gravity, and the acid material is oxidised electrolytically to produce ketones.
—L. A. C.

Mercury compounds of glucosides and process of making same. M. Hartmann, Assr. to Soc. of Chem. Ind. in Basle. U.S.P. 1,354,105, 28.9.20. Appl., 29.4.20

BY heating glucosides, such as amygdalin, arbutin, salicin, etc., with mercuric acetate solution, mercury derivatives are formed in which the mercury cannot be detected by means of soda lye. The products are white powders, readily soluble in water, but soluble only with great difficulty in organic solvents. They are only feebly toxic, do not produce cutaneous necroses, and are suitable for injections.

Pinacone diacetate; Preparation of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 327,128, 14.11.16.

AN almost quantitative yield of pinacone diacetate is obtained by treating a pinacone with acetic anhydride in the presence of a sulphonic acid, such as anthraquinone-1.5-disulphonic acid, toluenesulphonic acid, or naphthalenesulphonic acids, or of other strong acids, such as sulphuric acid.
—A. J. H.

Aluminium tannate; Preparation of basic ——. Chem. Fabr. auf Aktien (vorm. E. Schering). G.P. 328,341, 18.7.18.

A SOLPTION of alkali tannate is treated with an aluminium salt with addition of sufficient caustic alkali to keep the solution alkaline. The basic aluminium tannate thus prepared is a grey, odourless and tasteless powder, having the probable formula $(C_{14}H_{9}O_{9}.Al.OH)_2.C_{14}H_{10}O_9+12H_2O$, which is insoluble in cold water, soluble in acids and alkalis, and insoluble in hydrochloric acid having an acidity comparable to that of stomach juices.
—A. J. H.

Glycerin substitute. Akt.-Ges. f. Anilinfabr. G.P. 328,530, 15.11.18.

SOLUTIONS of salts are rendered much more viscous, and suitable for use as glycerin substitutes, by the addition of betaine. A mixture of 180 pts. of calcium chloride, 350 pts. of water, and 465 pts. of betaine has sp. gr. 1·2485 which is equal to that of 94·5% glycerin.—A. J. H.

Benzoic acid; Production of ——. J. B. Senderens, Assr. to Poulenc Frères. U.S.P. 1,365,956, 18.1.21. Appl., 7.7.19.

SEE E.P. 143,392 of 1919; J., 1920, 527 A.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photochemical processes; Influence of temperature on ——. J. Plotnikow. Z. wiss. Phot., 1921, **20**, 125—139.

NON-ILLUMINATED reactions have temperature coefficients which increase with decreasing temperature and approach unity at very high temperatures. The temperature coefficient (TC) of photochemical reactions has one of the values $1·03 \pm 0·03$; $1·20 \pm 0·03$, or $1·40 \pm 0·03$. The reactions in the photographic plate have the first value, whilst all reactions in which one of the halogens plays an important part have the third value. The reactions in the photographic plate are influenced by the wave length of the exciting light thus: ordinary plates with white light have TC 1·06, plates sensitised with Pinachrome have TC for blue light, λ= 436$\mu\mu$, 1·04; yellow light λ=579$\mu\mu$, 1·08, and for green light λ=546$\mu\mu$, 1·08; plates which have been previously subjected to very subdued light have TC for blue light 1·03 and for yellow or green light 1·04. (*Cf.* J.C.S., March.)—J. F. S.

Photometry; The wedge method of ——. G. I. Higson. Phot. J., 1921, **61**, 93—96.

IN the crossed wedge method of photometry first described by Luther (Brit. J. Phot., 1910, **57**, 664) the author uses generally for the first exposure either a shallow Goldberg wedge of 0·75 density increase per inch, for examination of the under-exposure portion of the plate, or a steep wedge of 1·9 per inch where the whole curve is required. For the second exposure, through a crossed wedge and negative, a wedge of gradation about 1·8 per inch is employed. A preliminary examination of the spectral selectivity of the wedges was made; it was found that calibration in a visual photometer gave the same result, within 1%, as photographic calibration with white light and a bromide emulsion. It is preferable to make the second exposure on a plate of very steep gradation such as a "process" plate. Both wedges used are scaled and, by selection of the actual exposures given, so that known lines on the scales correspond with definite exposures, the speed of the plate can be read off the final print. The sharpness of the final print is increased by treatment with Farmer's (thiosulphate-ferricyanide) reducer.—B. V. S.

Transparency of some yellow dyes for ultra-violet light. F. Stumpf. Z. wiss. Phot., 1921, **20**, 183—188.

A TABLE is given showing the transparency regions of solutions of 25 representatives of 11 types of dyestuffs. The most suitable for the preparation of an ultra-violet (transmission) filter are Tartrazine, Flavazine L., Cotton Yellow, Auramine, and Acriline Gold-yellow, which have a transparency region between the limits 350 and 300$\mu\mu$. Details are given of the method of determining transparencies photographically, using a quartz spectrograph and a Hartmann microphotometer, and the mathematical expression for the absorption coefficient is deduced. Curves are given showing the change of absorption with wave-length in the ultra-violet region for seven of these dyes at various concentrations.
—B. V. S.

[Photographic] developers; Exhaustion tests on ——. W. Ermen. Brit. J. Phot., 1921, **68**, 64—65.

A NUMBER of prints, which had all received the same exposure behind a Sanger-Shepherd test plate, were developed one after the other in the same lot of developer. The first print of a series was developed practically to finality and the subsequent prints developed to the same amount judging by the density

of the last visible square; the series was continued until this square could not be made visible in a reasonable time or until the time of appearance became unduly long, the time of appearance being taken as a measure of the activity of the developing solution. Number of prints was plotted against time of appearance, the resulting curve showing the method and rate of exhaustion of the developer. p-Aminophenol, monomethyl-p-aminophenol (metol), dimethyl-p-aminophenol, p-amino-o-cresol (monomet), methylamino-o-cresol, and p-amino-m-cresol were tested as carbonate developers at a strength of 2 g. per l. The curves show appreciable variation in time of appearance and in number of prints obtainable from the same quantity of developer. Quinol and chloroquinol, tested in the same way, but at 4 g. per l., show much longer times of appearance and much quicker rates of exhaustion. Curves are also given for these two developers in caustic alkali solution and in various mixtures with metol and monomet.—B. V. S.

Sodium silver thiosulphate; Reduction of —— by hydrosulphite. A. Steigmann. Kolloid Zeits., 1921, 28, 29—31.

A discussion of the physical development of the latent photographic image by sodium hydrosulphite in plates and papers after they have been fixed. The silver required for the development is obtained from the silver sodium thiosulphate of the fixing bath.—J. F. S.

[Photographic] silver images; Quinone and other oxidising agents for the conversion of —— into bromide or chloride. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1921, 68, 6—7.

Quinone and its sulphonic acid may be used in a similar way to various inorganic oxidising agents for the bleaching of silver images. In conjunction with hydrochloric or hydrobromic acid, or other suitable acid and a chloride or bromide, the silver is converted to the halide and the quinone reduced to quinol. The reaction is fairly rapid, there is no staining of the film, and the resulting halide image may be treated by any of the usual methods for reduction, intensification, etc.—B. V. S.

Colloid chemistry and photography. Lüppo-Cramer. Kolloid Zeits., 1921, 28, 25—29.

A discussion of the physical and chemical development of the latent image in photographic plates. —J. F. S.

Patents.

Coloured photographic pictures; Manufacture of ——. J. H. Christensen. E.P. 133,034, 22.9.19. Conv., 20.9.18.

If a film carrying a silver image and stained with certain dyes is treated with a suitable reducing agent, the dye is bleached in the neighbourhood of the silver image in proportion to the amount of the image, after which the silver may be removed by means of Farmer's reducer. Suitable dyes are Oxamin Fast Rose, Dianil Pure Blue, Aurophenine, Congo Pure Blue, Chicago Blue 6B, etc., mostly dianil dyes. With some dyes an ordinary developer, such as amidol, will reduce the dye, but most of them require a much stronger reducer such as sodium hydrosulphite. A convenient method is to add the dye to the emulsion before coating and after exposure to develop with a strongly restrained hydrosulphite solution which bleaches the dye at the same time. Two or more such coloured sensitive films may be coated on the same base, a multi-coloured image being then produced.—B. V. S.

Colour photography. Element for use in colour photography. R. L. Stinchfield, Assr. to Eastman Kodak Co. U.S.P. (A) 1,364,958 and (B) 1,364,959, 11.1.21. Appl. (A) 19.7.19 and (B) 6.2.20.

(A) A support, including a light-reflecting surface, is provided with an alternating series of filter areas and non-filter areas of approximately the same size and with a light-sensitive film yielding an opaque image. (B) The support for the colour-filters and sensitive film is made of opaque, light-absorbent material.—B. V. S.

Photographic film. F. W. Lovejoy, Assr. to Eastman Kodak Co. U.S.P. 1,342,590, 8.6.20. Appl., 6.9.19.

The sensitive layer on a film is protected from the injurious action of moisture by a transparent layer of fatty acid (palmitic or stearic acid), which is saponified and dissolved by the alkali carbonate in the developing bath.

Celluloid. S. H. Wood. U.S.P. 1,364,342, 4.1.21. Appl., 16.5.19.

A plastic, non-inflammable, transparent substance suitable for the manufacture of cinematograph films, consists of pyroxylin, naphthalene, ferric chloride, and gelatin.—A. J. H.

Silver print-out papers; Means for toning —— Akt.-Ges. f. Anilin-Fabr. G.P. 328,559, 13.10.17.

The toning bath contains in place of the usual gold salt a lead salt along with a salt of copper, cobalt, iron, nickel, manganese, uranium, tungsten, molybdenum, zinc, or bismuth.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrocellulose; Analysis of mixed acid for the production of ——. E. Berl and W. von Boltenstern. Z. angew. Chem., 1921, 34, 19—21.

A scheme for the analysis of nitrating acid after use is described. The total acidity is determined by titration with alkali, and the nitrogen acids by Arnd's method (J., 1921, 43 A). Nitrous acid and total organic matter are determined jointly in terms of $N/2$ permanganate solution by boiling with an excess of the latter and titrating the excess by means of potassium iodide and thiosulphate solution. Nitrous acid and readily oxidisable organic matter are determined jointly in terms of $N/2$ permanganate solution by titrating with the latter at 40°—45° C. Total organic matter alone is determined by boiling with permanganate solution as above, after destruction of nitrous acid by boiling the diluted sample with ammonium sulphate or urea. From the data furnished by these operations, which with the exception of Arnd's method are described in detail, the proportions of sulphuric, nitric, nitrous (N_2O_3), and oxalic acids, and cellulose products ($C_6H_{10}O_5$) are calculated by formulæ given.—J. H. L.

Patents.

Initial priming compositions [containing lead azide]; Manufacture of ——. W. Eschbach. E.P. 156,429, 14.2.20.

In the manufacture of priming compositions containing lead azide and another constituent, such as lead trinitroresorcinate, the mixing of the ingredients may be accomplished with greater safety if one of them, preferably the more absorptive one, is first treated with a "phlegmatising" medium, such as benzene. To enable the mixed composition to be pressed satisfactorily, a binding agent such as resin or colophony may be dissolved in the benzene.—W. J. W.

Powder; Progressively-burning —— and process of making the same. R. G. Woodbridge, jun., K. K. V. Casey, and C. I. B. Henning, Assrs. to E. I. du Pont de Nemours and Co. U.S.P. 1,354,442, 28.9.20. Appl., 25.2.20.

NITROCELLULOSE powder, the grains of which are coated with a deterrent (E.P. 127,871 and 127,872; J., 1919, 604 A), is agitated with a mixture of a black powder composition and dinitrotoluene or other non-volatile solvent of nitrocellulose, in order to produce a readily ignitable coating on the grains.

XXIII.—ANALYSIS.

Anemometers of great sensitivity, especially applicable to the investigation of slow rates of flow of gases; Thermal effect produced by a slow current of air flowing past a series of fine heated platinum wires, and its application to the construction of hot-wire ——. J. S. G. Thomas. Phil. Mag., 1921, 41, 240—258.

ELEVEN platinum wires of diam. 0·101 mm. were inserted in a flow tube, in close juxtaposition, transversely to the direction of flow of the air stream in the tube. The plane of the wires was parallel to the direction of flow of the stream, and the wires were heated by a current of 1·1 amp. The change of temperature of the individual wires produced by various velocities of the air stream up to 25 cm. per sec. was investigated, and it was found that the maximum increase of temperature attained a value of about 200° C. in the case of the last wire of the series. The results indicate that when a coil of fine wires is employed for purposes of heating a slow stream of air or other gas, fusion of one or more turns of the coil may result owing to the thermal effect produced in the wires by the heat convected by the stream, and also that in certain types of electrical gas meters the relative dispositions of the heating coil and platinum thermometers employed are of importance, otherwise anomalous results may be obtained when the velocity of the stream of gas is small. By suitable selection of two or more of the heated wires, the sensitivity of the directional type of hot-wire anemometer previously described (J., 1920, 803 A) may be very considerably increased.—J. S. G. T.

Melting points and critical temperatures; Simple method for the determination of ——. H. Rassow. Z. anorg. Chem., 1920, 114, 117—150.

FOR the determination of comparatively high melting points and critical temperatures an apparatus was devised consisting essentially of a solid copper cylinder 10 cm. long and 5 cm. diam., bored axially with a hole 6·5 cm. long by 3·5 mm. diam. and transversely through the middle with a hole of the same diam. intersecting the first. The first hole is to take the specimen under examination, the second to enable the specimen to be viewed with a telescope, with the aid of a bright source of light suitably placed to transmit light through the transverse hole to the telescope. The copper cylinder is heated electrically by a winding of nickel wire, the whole being suitably lagged and insulated. The temperature is measured by means of a thermo-couple inserted in a second hole bored close to and parallel with the axial hole and extending half way down the cylinder. The specimen to be examined is sealed in a small narrow tube of hard glass or transparent quartz, which is suspended in the axial hole to come within the field of vision of the telescope through the transverse hole. The apparatus can be used for determinations up to 1080° C. with an accuracy of approximately ±1° C. The following melting points were determined:—KI, 684·1°; KCN, 601·2°; NH_4Cl, 519·7°; NH_4Br, 541·9°; NH_4I, 551°±3° (considerable dissociation occurred); $N(CH_3)_4Cl$, 420°±10°; arsenic, 818°. The apparatus was also used for examining the miscibility of halogen salts of the alkali metals and ammonium. With a specially devised manometer a determination was made of the vapour pressure of ammonium chloride between 340° and 520°; the vapour pressure of NH_4Cl at its melting point is 34·5 atm.
—E. H. R.

Standard solutions; Normalities of ——. Y. Osaka. Mem. Coll. Sci., Kyoto, 1920, 4, 113—125.

TABLES are given showing the true normality at temperatures from 5° to 30° C. of a number of solutions standardised at 15°, 20°, or 25° C. in glass vessels. The solutions tabulated include oxalic acid ($N/1$ and $N/10$), hydrochloric, nitric, and sulphuric acids ($N/1$), sodium carbonate ($N/1$ and $N/10$), sodium hydroxide ($N/1$), sodium chloride, silver nitrate, and potassium permanganate ($N/10$ and $N/100$), and ammonium thiocyanate ($N/10$). In the case of $N/10$ and $N/100$ solutions, the changes of volume with temperature may be taken as equivalent without any greater error than 0·5%.
—E. H. R.

Iron; Volumetric determination of —— in the presence of a large quantity of hydrochloric acid. Meurice. Ann. Chim. Analyt., 1921, 3, 23—25.

POTASSIUM bromide is added to a ferrous salt solution containing a large proportion of hydrochloric acid, and a current of air is bubbled through the mixture while this is titrated with permanganate solution. The air is then passed through potassium iodide solution containing starch solution; as soon as all the ferrous salt has been oxidised, the next drop of permanganate solution added liberates bromine, which is carried over into the potassium iodide and a blue coloration results.—W. P. S.

Chromic acid; Iodometric determination of ——. I. M. Kolthoff. Z. anal. Chem., 1920, 59, 401—415.

THE conclusions published in a recent paper (J., 1919, 680 A) are confirmed. Potassium bichromate solutions, after addition of potassium iodide, may be accurately titrated at once with thiosulphate solution, provided at least 20 c.c. of $4N$ hydrochloric acid is added per 100 c.c. of the reaction liquid. Thiosulphate solutions may be standardised, with a possible error of less than 0·1%, by means of potassium bichromate, iodate, or bromate, oxalic acid, iodine, or cyanogen iodide, all of which can be purified without much difficulty. Potassium bichromate, as purchased, commonly contains sulphates and free chromic acid, and may be purified by recrystallising several times from water and dried at 120° C.; it should not be fused over a Bunsen burner.—J. H. L.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Atkinson, and Stein and Atkinson. Continuous furnaces. 4499. Feb. 8.

Barbet et Fils et Cie. Continuous rectification of liquid air etc. 4898. Feb. 11. (Fr., 11.2.20.)

Bassler. Drying materials. 4894. Feb. 11.

Coath. Lubricant. 5448. Feb. 17.

Deutsche Evaporator A.-G. Kilns. 5094. Feb. 14.

Greaves. Washing granular, powdered, etc. material. 4674. Feb. 10.

Herring. Filtering apparatus. 5111. Feb. 14.

Holland. Separation of materials. 5649. Feb. 18.

Humphries. Apparatus for drying, cooling, dehydrating, etc. 4781. Feb. 10.

Ison. Furnaces. 4607. Feb. 9.

Johnson (Badische Anilin u. Sodafabr.). 5127. *See* II.

Kilner. Apparatus for drying solids. 5115. Feb. 14.

Minton. Lubricants. 5275 and 5445. Feb. 16 and 17.

Seaman. Grinding and/or mixing mills. 4790. Feb. 10.

Straatman. Process for decolorising liquids. 5656 and 5765. Feb. 18 and 19. (Holland, 3.12.20, 13.1.21.)

Techno-Chemical Laboratories, Ltd., and Testrup. Drying. 5353. Feb. 16.

Techno-Chemical Laboratories, Ltd., and Testrup. Evaporators etc. 5488. Feb. 17.

Techno-Chemical Laboratories, Ltd., and Testrup. Heating processes. 5489. Feb. 17.

Complete Specifications Accepted.

27,519 (1919). Miller, and Fletcher and Co., Ltd. Filters. (158,387.) Feb. 16.

27,526 (1919). Haines. Filtering apparatus. (158,663.) Feb. 23.

28,778 (1919). Bedford and Oldroyd. Drying-apparatus. (158,734.) Feb. 23.

30,243 (1919). Carpenter. Collection of gases in chambers. (158,758.) Feb. 23.

26,025 (1920). McKean and Jones. Filtering-apparatus. (158,497.) Feb. 16.

26,556 (1920). Metcalfe. Continuous kilns of the tunnel type. (158,498.) Feb. 16.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Beilby. Carbonisation of coal, shale, peat, etc. 5352. Feb. 16.

Bentley. Gas-generators. 5138. Feb. 14.

Corthesy. Means for distilling or carbonising pulverulent fuel. 4961. Feb. 12.

Gartlan and Gooderham. Treatment of petroleum oils. 4496—7. Feb. 8.

Helps. Gas manufacture. 5573. Feb. 18.

Johnson (Badische Anilin u. Sodafabr.). Process for purifying gases. 5127. Feb. 14.

Lush. Treatment of producer gas etc. 4980. Feb. 12.

Maclaurin. Producer for dealing with low-grade fuels. 4337. Feb. 7.

Roberts. Recovering by-products from distillate gas. 4996. Feb. 12.

Rollason. Carbonisation of coal. 5035. Feb. 14.

Simpson. Apparatus for gasifying fuel. 4490. Feb. 8.

Szarvasy. Graphitising pre-formed carbon bodies. 4375. Feb. 7. (Hungary, 18.7.18.)

Szarvasy. Production of fine soot. 4376. Feb. 7. (Hungary, 18.7.18.)

Szarvasy. Manufacture of pure retort carbon. 4378. Feb. 7. (Hungary, 28.2.14.)

Complete Specifications Accepted.

12,134 (1917). Jones and MacDonald. Vertical retorts for destructive distillation of coal, shale, etc. (109,800.) Feb. 23.

18,252 (1919). Soc. de Fours à Coke. Coke ovens. (130,974.) Feb. 16.

21,969 (1919). Scrivner. Suction gas generators. (132,269.) Feb. 16.

27,090 (1919). Bale. Apparatus for carbonising coal, lignite, shale, etc. (158,622.) Feb. 23.

27,290 (1919). Brownlee and Uhlinger. Combustible gaseous compositions, especially for use in cutting, welding, etc. (158,633.) Feb. 26.

27,585 (1919). Duncombe and Singer. Fuel. (158,671.) Feb. 23.

27,770 (1919). Perry. Apparatus for distilling carbonaceous material. (158,394.) Feb. 16.

28,072 (1919). Naaml. Vennoots. Nederlandsche Lichte Olie Maatsch. Converting higher molecular hydrocarbons into lower molecular ones. (135,197.) Feb. 23.

28,253 (1919). White. Generators for producer-gas plants. (158,409.) Feb. 16.

30,117 (1919). Lowe. Plant for making blue water gas in conjunction with coal gas. (149,928.) Feb. 23.

III.—TAR AND TAR PRODUCTS.

Applications.

Atack. 4556. *See* XX.

Atack. Oxidation of hydrocarbons. 4557. Feb. 9.

Atack. Manufacture of anthraquinone or its derivatives. 5672. Feb. 19.

Bell Bros., Ltd., Lowe, and Roelofsen. Treating acid tar from washing benzol etc. for recovery of sulphuric acid etc. 5647. Feb. 18.

Chem. Engineering and Wilton's Patent Furnace Co., Ltd., Wilton, and Wilton. Distillation of tar. 4902. Feb. 11

Glysyn Corp. Chlorination of hydrocarbons. 5665. Feb. 18. (U.S., 31.8.20.)

Complete Specification Accepted.

26,759 (1919). Anderson and Meikle. Treatment of coal tar. (158,337.) Feb. 16.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Dreyfus. Manufacture of cellulose derivatives. 4639. Feb. 9.

Kampf. Recovery of carbon bisulphide in working up viscose. 4523. Feb. 8. (Ger., 28.10.20.)

Müller. Refining wood cellulose for manufacturing a cotton-like fibre. 4539. Feb. 8.

Stevenson. Manufacture of artificial silk from acetylcellulose. 5044. Feb. 14.

Tiburzi. Manufacture of paper. 5372. Feb. 16. (Ital., 24.7.20.)

Zdanowich. Manufacture of artificial silk, horsehair, etc. from cellulose acetates. 5318. Feb. 16.

Zdanowich. Manufacture of films, sheets, etc. from cellulose acetates. 5319. Feb. 16.

Complete Specifications Accepted.

17,082 (1919). Flaherty. Pyroxylin solvent and pyroxylin compositions. (158,586.) Feb. 23.

25,494 (1919). Du Pont de Nemours and Co. Pyroxylin compositions. (133,972.) Feb. 16.

28,191 (1919). Glanzfäden A.-G. Manufacture of a wool substitute from cellulose solutions. (135,206.) Feb. 23.
12,106 (1920). Summers. Process of retting flax etc. (158,807.) Feb. 23.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Clavel. Treatment of union or mixed fabrics. 4638. Feb. 9.
Farrell. Dye-jigs or becks. 4956. Feb. 12.
Frei. Apparatus for treating hanks of yarn with liquid. 4912. Feb. 11. (Switz., 12.2.20.)

Complete Specifications Accepted.

26,801 (1919). British Cellulose and Chem. Manuf. Co., Briggs, and Palmer. Dyeing or colouring fibres, threads, or fabrics. (158,340.) Feb. 16.
28,230 (1919). Calico Printers' Assoc., Ashton, and Mellor. Overprinting fabrics and yarns. (158,407.) Feb. 16.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

American Zeolite Corp. Preparation of artificial base-exchanging bodies. 5615. Feb. 18. (U.S., 19.2.20.)
Armour Fertilizer Works. Production of aluminium chloride. 4895. Feb. 11. (U.S., 24.3.20.)
Barbet et Fils et Cie. 4898. *See* I.
Bassett. 5752. *See* X.
Bassett. Manufacture of alkali and alkaline-earth sulphides. 5753. Feb. 19. (Fr., 20.2.20.)
Bell Bros., Ltd., and others. 5647. *See* III.
Brat. Recovery of nitrogen from peat etc. 5518—9. Feb. 17. (Ger., 18.2.20.)
Cumberland Coal Power and Chemicals, Ltd., Jaques, and West. Production of hydrogen. 4642. Feb. 9.
Deutsche Gold- u. Silber-Scheide-Anstalt, and Liebknecht. Manufacture of prussic acid. 4419. Feb. 7.
Dutt and Dutt. Preparation of titanium dioxide and alumina from bauxite. 5626. Feb. 18.
Griffith. 5669. *See* XXI.
Guignard. Extraction of nitrogen from nitrogen compounds of titanium. 5108. Feb. 14. (Fr., 19.3.20.)
Williams. Preparation of water-soluble phosphates. 4672. Feb. 10.

Complete Specifications Accepted.

15,764 (1918) and 395 (1919). Soc. Indus. de Prod. Chimiques. Separation of sodium and ammonium sulphates from the double salt. (128,895 and 158,282.) Feb. 16.
19,027 (1919). Macleod (Browning). Production of hydrogen sulphide. (158,288.) Feb. 16.
21,220 (1919). Matheson. Utilisation of alunite ore. (158,293.) Feb. 16.
29,030 (1919). Wang. Manufacture of ammonium perchlorate. (137,034.) Feb. 23.
31,816 (1919). Welter. Production of soda containing water of crystallisation. (136,841.) Feb. 23.
1012 (1920). Frischer. Concentration of dilute nitric acid. (137,834.) Feb. 23.
12,751 (1920). Terrisse and Levy. *See* XVI.

VIII.—GLASS; CERAMICS.

Applications.

Bailey. Kilns for firing pottery etc. 4974. Feb. 12.
Blythe. Brick, pottery, etc. kilns. 5399. Feb. 16.

IX.—BUILDING MATERIALS.

Application.

Passmore. Manufacture of fireproof or insulating material. 5742. Feb. 19.

Complete Specifications Accepted.

27,607 (1919). Crosbie. Asphaltic cement or bituminous composition for road making. etc. (158,674.) Feb. 23.
27,647 (1919). Baylor. Slow-setting cement and method of producing same. (158,390.) Feb. 16.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

A.-G. Brown, Boveri et Cie. Electrically-heated muffle furnaces. 5614. Feb. 18. (Switz., 18.2.20.)
Amalgamated Zinc (De Bavay's), Ltd. Recovery of lead and silver from sulphide ores etc. 4913. Feb. 11. (Australia, 13.2.20.)
Ashcroft. Metallurgy of metal-bearing ores or products. 5128. Feb. 14.
Bassett. Extraction of metals or metalloids from their oxides. 5752. Feb. 19. (Fr., 20.2.20.)
British Thomson-Houston Co. (General Electric Co.). Bearing material. 4512. Feb. 8.
British Thomson-Houston Co. (General Electric Co.). Electrodeposition of metals. 5112. Feb. 14.
Campbell, Gifford, and Waite. Electric furnaces for non-ferrous metals. 4432. Feb. 7.
Diepschlag. Working blast-furnaces etc. 4922. Feb. 11.
Diepschlag. Making ready fuel and smelting charges. 4923. Feb. 11.
France. Washing fine particles of minerals. 4388. Feb. 7.
Haglund. Treatment of copper-nickel matte. 4360. Feb. 7. (Norway, 10.2.20.)
Jackson (Soc. Metalurgica Chilena Caprum). Treatment of ores. 4782. Feb. 10.
Jackson (Leadizing Co.). Coating iron or steel articles with lead. 5759. Feb. 19.
Jones, and Minerals Separation, Ltd. Recovery of flotation agents from flotation products. 4911. Feb. 11.
Nettleton. Separating minerals etc. 4718. Feb. 10.
Perkins. Treatment of oxidised ores of copper. 5068. Feb. 14.
Rheinisch-Nassauische Bergwerks- u. Hütten A.-G., and Spieker. Extracting zinc from lead slags, zinc-retort residues, poor zinc ores, etc. 5472. Feb. 17. (Ger., 17.3.20.)
Stevens. Reduction of ores. 5120. Feb. 14. (U.S., 26.3.20.)

Complete Specifications Accepted.

26,470 (1919). Chikashige and Uno. Recovering selenium and noble metals from electrolytic slimes etc. (134,536.) Feb. 16.
26,530 and 28,633 (1919). Middlemiss. Treatment of finely-crushed ores etc. (158,320.) Feb. 16.
26,623 (1919). Ballantine. Production of rustless articles of steel. (158,329.) Feb. 16.
27,290 (1919). Brownlee and Uhlinger. *See* II.
29,031 (1919). Heskett. Manufacture of metal powders. (158,740.) Feb. 23.
30,960 (1919). British and Foreign Chemical Producers, Ltd. (Rhein. Kampferfabr.). Pickling iron or steel. (158,768.) Feb. 23.
3676 (1920). Schwartz. Silver-plating powder. (158,460.) Feb. 16.
12,372 (1920). Soncini. *See* XI.

XI.—ELECTRO-CHEMISTRY.

Applications.

British Thomson-Houston Co. 5112. *See* X.
Campbell, Gifford, and Waite. Graphitising-furnaces. 4431. Feb. 7.

Campbell and others. 4432. *See* X
Deutsche Gold- u. Silber-Scheide-Anstalt, and Liebknecht. Platinum anodes. 4420. Feb. 7.
Hiorth. Induction furnaces. 5501. Feb. 17. (Norway, 21.2.20.)
Michel. Manufacture of electrodes. 4858. Feb. 11.
Szarvasy. 4375. *See* II.
Szarvasy. Manufacture of carbon electrodes. 4377. Feb. 7. (Hungary, 29.11.17.)

COMPLETE SPECIFICATIONS ACCEPTED.

26,470 (1919). Chikashige and Uno. *See* X.
28,772 (1919). Powell. Primary batteries. (158,733.) Feb. 23.
8444 (1920). Soc. Metallurgique du Frayol. Electric furnaces. (157,051.) Feb. 16.
12,372 (1920). Soncini. Electric crucible furnaces. (142,836.) Feb. 16.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Dutt. Treatment and decolorisation of vegetable oils and glycerin. 4613. Feb. 9.
White (Safetee Soap Corp.). Cocoa-butter compositions. 5668. Feb. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

17,222 (1919). Barbet et Fils et Cie. Continuous distillation of glycerin from residue obtained in distilling fermented liquors. (129,649.) Feb. 23.
19,883 (1920). Rogers. Extraction of oils from fatty substances. (147,834.) Feb. 23.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATION.

Bakelite Ges., and Hessen. Manufacture of condensation products from phenols and aldehydes. 5257. Feb. 15. (Ger., 1.3.20.)

COMPLETE SPECIFICATION ACCEPTED.

31,393 (1919). Vickers, Ltd., Ioco Rubber and Waterproofing Co., Ltd., and Nuttall. Condensation of phenolic bodies with aldehydic compounds. (158,447.) Feb. 16.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATION.

Davidson. Coagulant for rubber latex. 5401. Feb. 16.

COMPLETE SPECIFICATION ACCEPTED.

32,259 (1919). Smith. Process of devulcanising rubber. (158,783.) Feb. 23.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATION.

Manvers. Preparation of hides for tanning. 5677. Feb. 19.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Haege. Production of fertilisers containing phosphoric acid and potash. 5195. Feb. 15.
Williams. 4672. *See* VII.

COMPLETE SPECIFICATION ACCEPTED.

22,020 (1920). Tavroges, Roche, and Martin. Treatment of whey produced in cheese manufacture and production of nitrogenous matter applicable as a fertiliser. (158,816.) Feb. 23.

XVII.—SUGARS; STARCHES; GUMS.

COMPLETE SPECIFICATION ACCEPTED.

12,751 (1920). Terrisse and Levy. Regenerating hydrochloric acid used in the manufacture of glucose. (154,170.) Feb. 16.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Briscoe. Malting. 5556. Feb. 18.
Gilmour. Manufacture of yeast. 5444. Feb. 17.

COMPLETE SPECIFICATION ACCEPTED.

17,222 (1919). Barbet et Fils et Cie. *See* XII.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

American Zeolite Corp. 5615. *See* VII.
Dunham. Production of casein etc. 5005. Feb. 12.
White. 5668. *See* XII.

COMPLETE SPECIFICATIONS ACCEPTED.

11,080 (1917). Paterson. Sterilising liquids. (158,578.) Feb. 23.
27,019 (1919). Rushton. Softening or purification of water. (158,620.) Feb. 23.
27,773 and 30,595 (1919) and 19,605 (1920). Townsend. Manufacture of articles of food. (158,684.) Feb. 23.
14,624 (1920). Sgalitzer. Manufacture of a food preparation from blood. (143,919.) Feb. 16.
22,020 (1920). Tavroges and others. *See* XVI.
26,223 (1920). Magrath. Treatment of water for softening, sterilising, etc. (158,498.) Feb. 16.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Atack. Condensation of *o*-benzoylbenzoic acid or its derivatives. 4556. Feb. 9.
Bader, and British Cellulose and Chem. Manuf. Co. Manufacture of acetic anhydride etc. 4637. Feb. 9.
Badische Anilin u. Sodafabrik. Manufacture of alcohol. 4634. Feb. 9. (Ger., 9.2.20.)
Glysyn Corp. 5665. *See* III.
Soc. Chim. Usines du Rhône. Manufacture of saccharin. 5019. Feb. 12. (Ger., 25.6.20.)
Zinke. Manufacture of perylene. 5103. Feb. 14. (Austria, 2.7.20.)
Zinke. Manufacture of dioxyperylene. 5104. Feb. 14. (Austria, 2.7.20.)

COMPLETE SPECIFICATION ACCEPTED.

21,371 (1920). Henning. Non-flammable volatile liquid. (158,494.) Feb. 16.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATION.

Griffith. Schlippe's salts etc. 5669. Feb. 19.

COMPLETE SPECIFICATION ACCEPTED.

27,574 (1919). Camiller and Hay. Multicolour screens for colour cinematography and photography. (158,670.) Feb. 23.

XXIII.—ANALYSIS.

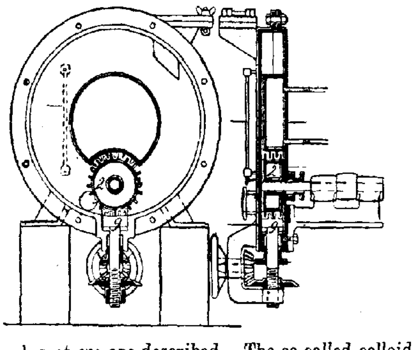
APPLICATION.

Andrews, and Victoria Falls and Transvaal Power Co. Quantitative detection of carbon dioxide and combustible gases containing carbon. 5654. Feb. 18.

I.—GENERAL; PLANT; MACHINERY.

Colloid mill and its application to chemical technology. B. Block. Verein deutsch. Chem., 11.9.20. Z. angew. Chem., 1921, 34, 25—30. (*Cf.* J., 1920, 589 A.)

The physical conditions governing the production of disperse phases are briefly reviewed and various types of mills hitherto available for the production



of such systems are described. The so-called colloid mill (see fig.) comprises a drum, 2, provided with a number of arms rotating in a chamber containing the substance to be dispersed and the dispersing medium. The liquid is projected by the rotating arms against obstructions, 9, and dispersion of the substance results. The principal difficulties in the operation of the mill consist in rendering the axle-packing tight and in attaining a sufficiently high circumferential velocity of the drum. In the case of a colloid mill employed for dispersing cellulose this material was reduced to particles of the order of 0·0003 mm. when the circumferential velocity of the drum was 20 m. per sec., whilst when the circumferential velocity was 30 m. per sec. the size of the particles was reduced to 0·0001 mm., and the true colloidal condition was attained when the velocity was 40 m. per sec. Smaller mills, with which circumferential velocities up to 500 m. per sec. may be attained, are contemplated. The development of such mills depends upon the discovery of a steel of extremely high tenacity. By employing two drums rotating in opposite directions the necessary circumferential velocity can be reduced. The operation of the mill can also be expedited by employing suitable accelerators of the dispersion process. The lay-out of installations for the production of colloidal cellulose for the manufacture of insulating materials etc. and of colloidal shale for the separation of the oil is detailed.
—J. S. G. T.

Alinement charts: Construction and use of ——. A. J. V. Umanski. Chem. Trade J., 1921, 68, 233—236, 269—272.

An account of the methods of nomography and their application to cases such as the adiabatic compression of gases, evaporation of solvents, reducing gaseous volumes to normal temperature and pressure, condensing coils and heating plant, the design of crystallising tanks, and heat transmission between moving liquids.

Patents.

Coal, minerals, or the like; Washers for classifying ——. L. Malécot. E.P. 145,444, 18.6.20. Conv., 18.6.18.

A vessel with vertical sides is provided with an offset portion at the top, having an inclined outer wall and communicating with the main vessel through an opening in the vertical wall which forms a partition between the two portions. The material is fed from a hopper on to the inclined wall and passes downwards through still water into an upward current in the vertical vessel. The heavier portion sinks to the bottom of this vessel, and the lighter portion is carried upward by the water and thence along a horizontal channel on the side of the vertical vessel opposite to that at which the material is admitted.—W. F. F.

Centrifugal pumps for acids. Chem. Fabr. vorm. Weiler-ter Meer. E.P. (A) 145,803 and (B) 146,409, 2.7.20. Conv., 28.9.16 and 19.11.17.

(A) A pump has a vertical spindle surrounded by a tubular acid trap and carried to a considerable height above the guide-box, the top of the tubular trap being approximately closed by a collar or the like. The head of the inflowing acid must be sufficient to cause the acid to rise through the guide-box into the trap and yet not sufficient to cause the acid to overflow above the trap when the pump is at rest. The pump is designed so that all interior parts may be machined, so that it can be made of, *e.g.*, wrought iron. (B) To prevent the action of the pump emptying the trap, a passage or pipe is provided connecting the trap directly with the inlet pipe.—B. M. V.

Furnace; Heat-treating ——. C. J. Kirk. E.P. 155,712, 24.12.19.

A chamber to receive the goods under treatment is divided into two compartments by a longitudinal wall in which openings are left at top and bottom for circulation of air. Heat is applied by means of flues in the walls and arch of the furnace. Between the flues and chamber is a space through which the air from the chamber can circulate. This space may conveniently be formed by building the inner wall of the side flues of hollow tiles which are open at top and bottom to the chamber.—B. M. V.

Furnaces; Rotary ——. F. Derneden. E.P. 156,835, 26.6.19.

A rotary furnace is provided with a number of longitudinal channels surrounding the axis of rotation; the channels are connected together, and also to an axial passage if desired, by means of inclined passages, so that the material passes from one longitudinal channel to the next upon rotation of the furnace. The outer channels, but not the axial passage, may be subdivided by cross partitions.
—B. M. V.

Surface combustion furnace. F. J. Denk. U.S.P. 1,365,769, 18.1.21. Appl., 5.12.19.

The space to be heated is surrounded by spaced refractory material divided into a number of sections. Combustible gas is supplied separately to each section, and means are provided for drawing combustion products away from contact with the articles which are being heated.—W. F. F.

Tunnel kiln. F. K. Meiser. G.P. 327,089, 15.7.19. Addn. to 319,440 and 320,800 (J., 1920, 475 A, 647 A).

The crucibles are arranged in a circle and connected by fixed tubes provided with valves. The gas is led into the crucibles through flexible tubes or by means of a circular channel.—L. A. C.

Pulverising apparatus. W. L. McLaughlin. E.P. 156,852, 28.8.19.

A rod-mill is provided with grinding rods of about the same length as the mill, but of several different diameters, so that the smaller rods enter the interstices between the larger and render the mill

suitable for fine grinding, *e.g.*, of coal. The material is fed evenly over the whole length of the mill by means of a fixed hollow shaft or casing provided with spiral slots and a spiral conveyor. The material that is sufficiently ground is kept in suspension by a series of high-pressure air jets within the mill and removed through one end of the mill by a low-pressure suction.—B. M. V.

Grinding mill. H. W. Hardinge. U.S.P. 1,366,651, 25.1.21. Appl., 22.10.19.

A GRINDING mill has, at its outlet end, a classifying compartment shaped as a truncated cone and containing loose tapering rods with their small ends towards the outlet, which is situated at the small end of the outer conical drum.—B. M. V.

Centrifugal machine. P. T. Sharples. E.P. 157,688, 22.6.20.

IN centrifugal separators in which a carrier liquid is used to prevent the separated material from sticking to the walls of the basket, a diaphragm is provided near the bottom of the basket, and extending nearly to its walls. The inlet pipe is in the form of a double conduit, the carrier liquid being supplied through the duct below the diaphragm, whilst the pulp to be separated is supplied through the other duct above the diaphragm.—B. M. V.

Emulsions and the like [e.g., wool washing effluent]; Treatment of ——. W. Broadbridge, E. Edser, and Minerals Separation, Ltd. E.P. 157,490, 18.7.19 and 12.8.19.

THE emulsion (*e.g.*, wool washing effluent) is subjected to aeration and agitation by means of mechanical beaters which produce a vortex and violent turbulence, the liquid passing through the zone of turbulence several times, and a portion when completely aerated rising through a grid or other perforated division to a zone of comparative quiet where the floating values are removed. Frothing and modifying agents may be added and the process worked at an elevated temperature.
—B. M. V.

Specific gravity of flowing liquid; Apparatus for indicating and recording ——. S. D. Wells and R. J. Marx. E.P. 158,151, 21.1.20.

A BULB with inlet and outlet tubes, the latter arranged above the former, forms one arm of a balance, the other arm being provided with an adjustable counter weight. A portion of the liquid of which the density is to be measured flows (without mechanical connexion) into a funnel on the inlet tube, which is substantially on the pivotal axis, and is discharged through a vented goose neck to an outlet similarly situated.—B. M. V.

Reaction spaces; Filling material for ——. A. M. Fairlie. U.S.P. 1,365,671, 18.1.21. Appl., 23.3.18.

REACTION spaces are filled with hollow blocks open at both ends, each containing at least one complete turn of a helical vane supported by an axial rod.
—W. F. F.

Dryers; Method of and apparatus for recovering heat from ——. J. O. Ross, Assr. to B. F. Sturtevant Co. U.S.P. 1,365,790, 18.1.21. Appl., 7.3.18.

HOT moist air from a dryer is mixed with atmospheric air at a substantially lower temperature, and the condensed water removed, leaving the air saturated at the lower temperature. The air is then re-heated for drying purposes.—W. F. F.

Drying gas; Apparatus for recovering heat and solid particles in suspension from a ——. R. G. Brindle and A. H. Flint, Assrs. to Corn Products Refining Co. U.S.P. 1,366,712, 25.1.21. Appl., 3.7.18.

PART of a liquid (which is to be evaporated by contact with a heated drying-gas) is sprinkled into a chamber through which is also passed the drying-gas from the evaporating chamber, which may be carrying particles of the dried liquid in suspension. The liquid after it has collected the heat and dust is returned to the original supply tank. The chamber may be provided with baffles over which the liquid trickles, or other means of increasing the surface of the absorbing liquid.—B. M. V.

Drying ovens; Process and apparatus for preventing fires in direct-fired ——. P. Schneider. G.P. 326,403, 30.11.17.

STEAM as well as air is mixed with the furnace gases, whereby sparks are extinguished, and improvement effected in the quality of the dried materials.
—J. S. G. T.

Drying apparatus. O. Pfeiffer. G.P. 327,731, 20.8.18.

AN apparatus for drying loose material comprises a number of drying chambers connected with chests for the supply and withdrawal of the air employed for drying, the whole being mounted so that it can be rotated about a fixed horizontal axis. The charging appliance may be arranged immediately above the drying apparatus, which may be emptied into a chamber immediately underneath. During the drying operation the partitions separating the drying chambers are in a horizontal position, whilst for discharging purposes the apparatus is rotated until the partitions are vertical.—J. S. G. T.

Volatile solvents; Process of recovering ——. S. S. Sadtler. U.S.P. 1,365,791, 18.1.21. Appl., 18.5.20.

THE vapour of the solvent is absorbed by a mixture of sperm oil, lard oil, petroleum oil, and alcohol.
—W. F. F.

Filter. J. P. Winters and M. McCamon. U.S.P. 1,366,143, 18.1.21. Appl., 23.4.20.

A CLOSED tank is provided with a supply pipe extending downwards nearly to the bottom, and an inverted cone is secured at its apex to the bottom of the pipe with its rim spaced from the wall of the tank. A horizontal zone of filtering material is arranged above the cone. There is an outlet valve just below the rim of the cone and an overflow above the zone of filtering material.—W. F. F.

Acid receptacles; Outlet for ——. F. W. de Jahn, Assr. to General Chemical Co. U.S.P. 1,366,170, 18.1.21. Appl., 6.5.18.

A RECEPTACLE having an acid-proof lining within a corrodible outer casing is provided with an outlet pipe attached to the casing and having an extension extending into the refractory lining but spaced therefrom and with acid-proof packing in the space.
—B. M. V.

Steam generator. H. A. Nicholson, Assr. to E. A. Craig. U.S.P. 1,366,207, 18.1.21. Appl. 7.1.18.

A GAS producer is surrounded at one part by a water-jacket, and this in turn by a combustion chamber and then by a feed water coil. Feed water is passed through the coil to the water-jacket and thence to a battery of pipes in the combustion chamber. The pipes communicate with a steam chamber from which steam may be withdrawn.
—W. F. F.

Crystallising receptacle. F. Merz. U.S.P. 1,366,474, 25.1.21. Appl., 24.2.20.

THE walls of a crystallising vessel are made of flexible material so that crystals may be readily detached.—B. M. V.

Carrying out chemical reactions in an artificial atmosphere; Process and plant for ——. M. C. J. E. de Loisy. U.S.P. 1,366,720, 25.1.21. Appl., 26.6.19.

THE operations are conducted in a furnace which is open but which is within a closed chamber containing the required gas.—B. M. V.

Scraper and agitator; Combined ——. A. E. Flowers, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,366,777, 25.1.21. Appl., 8.1.20.

A VESSEL of circular section is provided with a rotary scraper and agitator. The actuating arms extend nearly to the walls of the vessel and carry at the ends pivoted scrapers; the main part of each scraper trails behind the end of the arm, but the forward part is in the form of a knife, inclined forwards and outwards, which removes material from the wall of the vessel.—B. M. V.

Heat-treating bodies; Process of ——. N. H. Fooks. U.S.P. 1,366,778, 25.1.21. Appl., 17.7.20.

A FLUID-TIGHT pressure-resisting vessel contains a fixed gas and a liquid. The temperature of the vessel is maintained above the boiling point of the liquid at normal pressure but below the boiling point at the pressure used. The articles to be treated are inserted, treated, and removed while substantially maintaining the required pressure and temperature.—B. M. V.

High-pressure-air refrigerating machine. Ges. für Lindes Eismaschinen A.-G. G.P. 323,950, 16.1.18.

AIR is compressed under a very high pressure and then expanded to a lower pressure, but still above atmospheric pressure, say 50 atm., whereby the efficiency of the refrigerating process is increased on account of the disproportionately higher value of the specific heat of air at the higher pressures. For each step down in temperature an additional expansion cylinder with compressor and refrigerating appliance is employed. In many cases the machine can compete successfully with modern types of refrigerating machines employing liquid carbon dioxide, ammonia, etc. as refrigerating agent. The machine is especially applicable for use in connexion with chemical processes carried out in an enclosed space, in mines and under water.
—J. S. G. T.

Filter for purification of gases. Deutsche Luftfilter-Bauges. m.b.H. G.P. 325,782, 10.10.17.

A FILTER frame in the form of a cage is built up of a number of layers of filtering material supported on separate screens, individually removable or replaceable. Pockets on the gas inlet side of the filter open downwards, while those on the gas exit side open upwards. A number of cages may be held together by means of an angle iron, and the whole made to revolve about a common axis.—J. S. G. T.

Purification of gases; Plant for electrical —— employing perforated electrodes. Siemens Schuckertwerke G.m.b.H. G.P. 325,956, 4.6.18.

THE collecting space for material precipitated from the gas is covered by the precipitating electrodes, above which the high-tension electrodes are disposed both transversely to and along the direction of flow of the gas stream. In this manner, precipitation is effected both by gravity and the electrical field.—J. S. G. T.

Purification of gases; Multiple-stage liquefaction process for the ——. Ges. für Lindes Eismaschinen A.-G. G.P. 327,127, 26.3.19.

THE gas to be purified by liquefaction is first cooled at a moderate pressure by the evaporation and expansion of a part of the gas already liquefied, and both portions are subsequently mixed, compressed, and liquefied under high pressure. Purification is effected during the stages of the cooling process.
—J. S. G. T.

Evaporator with chain stirrer. Gebr. Heine. G.P. 325,799, 16.6.18.

AN evaporator in the form of a bowl or trough is provided with a stirrer consisting of a horizontal frame formed of rods, parallel to the axis of rotation, from which the chains hang freely. The chains cut through the froth on the surface of the liquid, whereby the bubbles burst and the evaporating surface is constantly renewed.—J. S. G. T.

Evaporation of liquids; Frothing process for the ——. Wo. Ostwald. G.P. 327,976, 30.11.18.

To facilitate the production of a fine mist, substances are added to the liquid which reduce its surface tension. Frothing may be effected by the introduction of a gas or by the vapours of low-boiling liquids or, if desired, temperature and pressure conditions may be adjusted so that the lightest constituent of the liquid itself is vaporised and acts as the frothing agent.—J. S. G. T.

Converting liquids or pasty masses [e.g., glycerin fermentation residues] into a dry and easily extractable condition; Process for ——. K. Ebers. G.P. 326,728, 16.12.17.

A DISTRIBUTING medium, insoluble in the extracting medium to be employed, is added to the liquid or pasty mass, and the mixture atomised in a stream of dry air. The residue is obtained in an easily extractable form. In applying the process to the treatment of the residues remaining after the separation of the bulk of the glycerin from glycerin fermentation masses, common salt or any salt insoluble in alcohol or ether is employed as distributing medium, and the dried mixture is extracted with alcohol or ether to recover the remainder of the glycerin. Slime and albuminous substances are by this process converted into forms which do not affect the extraction of the dried residue.
—J. S. G. T.

Cooling or heating systems. Maschinenfabrik Esslingen. G.P. 327,290, 19.9.18.

A SYSTEM of cooling or heating pipes is built up of a number of U-shaped members, and so can be made of cast acid-resisting silicon-iron. A lateral branch pipe of smaller cross-section opens from the bottom of each member, enabling deposits and condensed liquid to be removed from the system.—J. S. G. T.

Metallic body to be enclosed in a vessel wherein a high vacuum is to be maintained at a high temperature; Production of a ——. Schott u. Gen. G.P. 330,372, 18.4.18.

THE body is constituted of a metal which has been melted *in vacuo*, so that no further gases or impurities are evolved on subsequent heating.—J. S. G. T.

Sedimentation apparatus. The Dorr Co., Assees. of C. L. Peck. E.P. 133,716, 11.10.19. Conv., 5.10.18.

SEE U.S.P. 1,337,094—5 of 1920; J., 1920, 393 A.

Dryers; Centrifugal ——. G. H. Elmore. E.P. 158,152, 9.2.20.

SEE U.S.P. 1,342,743 of 1920; J., 1920, 538 A.

Mixing machines [for concrete etc.]; Mechanical ——. H. Martinez. E.P. 157,557, 20.10.19.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Formation and chemical constitution of ——. F. Fischer and H. Schrader. Brennstoff-Chem., 1921, 2, 37—45.

THE authors conclude from their researches that the cellulose disappeared from the plant substances from which the coal was formed, being decomposed chiefly by bacterial action, and the coal was formed by the conversion of the lignin into humic substances, the percentage of wax and resin increasing owing to the disappearance of the cellulose. The phenols obtained in low-temperature tar are formed by the decomposition of these humic acids in distillation, and the hydrocarbons from the bitumen. (*Cf.* J.C.S., Mar.)—W. P.

Gas purification [from sulphur]; Alkalinity tests in ——. C. H. Stone. Amer. Gas Assoc. Gas J., 1921, 153, 341—342.

THE effect of the addition of lime to natural oxide of iron in a purifier is not to increase the absorptive power for sulphur, but to increase the speed of absorption. Calcium or magnesium carbonate is as effective as calcium hydroxide. Their efficacy is due to neutralisation of the sulphuric and thiocyanic acids formed. 2% of calcium carbonate gave the best result. Fouled oxide allowed to stand out of contact with air cannot be revivified, owing to the formation of iron disulphide. The absorption velocity in a purifier increases with the temperature, but the practical limit is reached at about 40° C. owing to the risk of the heat of reaction liberating sulphur compounds. Ferrous sulphate and sulphur do not affect the action of oxide except by dilution.—C. I.

[Lubricating] oils; Cold test apparatus for ——. G. H. P. Lichthardt. J. Ind. Eng. Chem., 1921, 13, 145—146. (*Cf.* Martens, J., 1890, 772.)

THE oil to be tested is placed in a glass tube fitted in an inclined position through a tank containing a freezing mixture (acetone and carbon dioxide snow); the lower end of the tube is bent upwards and connected with an air supply of constant pressure. When the oil becomes solid and does not move under an air pressure of 16 in. of water, the temperature is allowed to rise slowly; the temperature at which the oil appears in the part of the tube protruding from the tank is taken as the "cold test," *i.e.*, the lowest temperature at which the oil will flow.—W. P. S.

Detecting fire-damp etc. Erlwein and Becker. *See* XI.

Gas analysis. Möller. *See* XXIII.

Flue gas. Milligan and others. *See* XXIII.

PATENTS.

Briquette manufacture. J. F. Lovejoy. U.S.P. 1,366,091, 18.1.21. Appl., 15.10.19.

THE briquettes travel downwards through a zigzag passage and furnace gas passes upwards over the lower portion of the passage to carbonise the briquettes. The gas then passes through perforations in the walls into the upper portion of the passage to preheat the descending briquettes by direct contact therewith.—W. F. F.

Coal briquettes; Manufacture of coherent —— *without the use of foreign binding material.* O. Dobbelstein. G.P. 329,054, 25.3.14.

HARD coal dust is mixed with gas-coal dust or sludge, and the mixture briquetted under a pressure of 3000—4000 atm.—B. V. S.

Crude-oil-refining process. J. G. P. Evans. U.S.P. (A) 1,366,642 and (B) 1,366,643, 25.1.21. Appl., (A) 11.11.19 and (B) 15.12.19.

(A) ONE end of a body of the oil is heated so that the temperature decreases towards the opposite end. The vapour arising from the hottest portion of the oil is brought into contact with the vapour arising from the cooler portions, whereby portions of the hotter vapour are condensed, the fractions condensed over successively cooler portions of the oil being collected separately. (B) A body of the oil in an upright conical vessel is heated to a higher temperature at the top than at the bottom. The vapour passes downwards around the walls of the vessel to effect a heat exchange between the vapour and the liquid, and the portions of liquid condensing from the vapour at different vertical heights are collected separately.—L. A. C.

Gas; Apparatus for the manufacture of ——. J. E. Christopher, Assr. to T. H. Byrom. U.S.P. 1,367,512, 1.2.21. Appl., 28.2.20.

SEE E.P. 142,163 of 1918; J., 1920, 441 A.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Yield of low-temperature tar from lignite. Fischer and others. *See* III.

PATENTS.

Coal, oil shale, wood, peat, and the like; Process and apparatus for the low and medium temperature carbonisation of ——. J. R. Garrow. E.P. 158,002, 31.7.18.

A ROTARY retort, resembling a cement kiln, in combination with a gas producer is used to effect the carbonisation of a fuel at low or medium temperature by the heat of the producer gas, without burning the latter. The direct contact possible between the hot gas and fuel gives a high thermal efficiency and, owing to the avoidance of local overheating, an improved yield of oil. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 13,830 of 1899, 18,279 of 1900, and 1676 of 1914; J., 1900, 725; 1902, 33; 1915, 604.)—C. I.

Glow discharge lamps; Electric gas filled ——. A. Lederer. E.P. 12,158, 16.5.14. Conv., 19.5.13.

A GLOW discharge lamp of the type filled with one or more of the rare gases is rendered suitable for operation by an alternating current by arranging the electric circuit within the lamp to act as a rectifying valve of the Wehnelt type. Thus, one of the electrodes may consist of a refractory metal or conducting material covered with a metal compound or salt and so arranged that on starting the necessary heat is imparted to the covering to enable the lamp to light up. Alternatively, one of the electrodes may be considerably larger than the other.—J. S. G. T.

Gas and vapour lamp; Electric ——. J. Pintsch A.-G. G.P. 328,455, 28.10.15.

Cadmium free from oxide and adsorbed gases, prepared by distillation in a high vacuum, is employed as cathode for the production of an arc discharge in a space containing a small quantity of one of the rare gases. In part of the discharge the cadmium vapour is made luminous, so that when neon is employed in the lamp, a white light results. —J. S. G. T.

Metallic body to be enclosed in an evacuated vessel. G.P. 330,372. *See* I.

III.—TAR AND TAR PRODUCTS.

Low-temperature tar from lignite; Variations in the yield of ——. F. Fischer, W. Schneider, and A. Schellenberg. Brennstoff-Chem., 1921, **2**, 52—58.

The effect of drying lignite on the yield of low-temperature tar has been investigated. Taking the yield from freshly mined lignite as 100, the yield of tar from air-dried lignite was 74, from lignite dried at 105° C. in a stream of carbon dioxide 72, and from lignite dried at 105° C. in air 56. These differences are probably due to oxidation of the lignite by the oxygen in the air. The individual constituents of the tar do not diminish to an equal extent.—W. P.

Benzol acid sludge; Treatment of ——. Stephenson. Gas World, Feb. 5, 1921, Coking Sect., 19—20.

A tall narrow still is unsuitable for the recovery of benzol from acid sludge, as frothing occurs. Steam should be introduced through a number of orifices. A still has been designed by the author on these lines; it also provides for a jet of ammonia gas being introduced into the swan-neck to neutralise the sulphur dioxide given off. Benzol suitable for the market is thus produced direct. 20% of benzol was recovered and the residual acid liquor varied in strength from 33 to 55%, calculated as H_2SO_4. The black resinous residue containing 1% ash is suitable as a fuel; or if washed with water, dried, and distilled, it yields 15% of oil. Up to 8% of pyridine was found in the acid liquor.—C. I.

Aniline; Determination of —— and its volumetric diazotisation. T. Sabalitschka and H. Schrader. Z. angew. Chem., 1921, **34**, 45.

Aniline solutions, containing at least 2—3 mols. of sulphuric acid per mol. of aniline, and kept cold by means of ice-water, may be accurately titrated with $N/1$ sodium nitrite solution, with the aid of spot tests on potassium iodide-starch paper. The nitrite solution may be added several drops at a time at first, but as the reaction becomes slower the additions should be made drop by drop and the liquid must fail to react with the test paper before the next drop is added. The titration is continued until a positive reaction is obtained ¼ hr. after the addition of the last drop. In order to reduce the error due to the withdrawal of numerous drops for the spot tests, an approximate preliminary titration is desirable. A titration occupies ¾—1¼ hr. The nitrate solution may be standardised against pure aniline or sodium sulphanilate. In test solutions containing 1·018 g. and 1·686 g. of aniline per 100 c.c., the authors found 1·015 g. and 1·689 g. respectively.—J. H. L.

Cresols; Nitrobenzoates of the three ——. E. Hänggi. Helv. Chim. Acta, 1921, **4**, 23—25.

The *o*-nitrobenzoyl derivatives of *o*-, *m*-, and *p*-cresol have the respective melting points, 68°—69°, 58·5°—60°, and 78°—79·5° C.; the *m*-nitrobenzoyl-derivatives, 96·5°—97·5°, 63°—64°, and 77°—78° C., and the *p*-nitrobenzoyl-derivatives, 92°—93°, 85°—85·5°, and 96·5°—97·5° C. (*Cf.* J.C.S., Mar.) —T. H. P.

Orthodichlorobenzol solvent. Gardner. *See* XIII.

Patents.

Transformer oil; Process for the manufacture of ——. M. Melamid. E.P. 143,193, 14.2.20. Conv., 15.5.19.

An anthracene oil fraction free from phenol is treated with oxidising agents, *e.g.*, a mixture of potassium bichromate or permanganate and sulphuric acid, or the like, below 0° C., *e.g.*, at −15° to −20° C., or below normal temperature, *e.g.*, at 0°—5° C., in the presence of a suitable solvent, *e.g.*, benzene. The supernatant oil is then separated from the resinous deposit, and is distilled *in vacuo*. —L. A. C.

Sulphur compounds of the thiophene series; Manufacture of ——. H. Scheibler. G.P. 327,050, 29.4.14.

The crude tar oil from bituminous rock is heated with soda-lime, and after separation from the inorganic bases, the product is treated with alkyl magnesium halides. The oil obtained by decomposition of the organo-magnesium compounds is distilled over sodium, yielding a colourless or yellowish oil consisting of a solution of thiophene compounds in hydrocarbons. (*Cf.* J., 1920, 55A.)—L. A. C.

p-Nitrotoluene-o-sulphonic acid; Manufacture of ——. W. Osakeyhtiö. G.P. 327,051, 9.7.18.

The product obtained by sulphonating *p*-cymene is treated at 40°—60° C. with nitric acid, nitric acid and sulphuric acid, or with nitrates, and the *p*-nitrotoluene *o*-sulphonic acid is isolated as the sodium salt.—L. A. C.

Diphenylene sulphide; Manufacture of ——. *Manufacture of diphenylene disulphide [thianthrene].* O. Lange, M. W. Widmann, and A. Wennerberg. G.P. (A) 330,833, 12.2.20, and (B) 330,834, 26.3.20.

(A) 2.2′-Dihydroxydiphenyl, prepared by fusing diphenylene oxide from coal-tar with alkalis, is heated with phosphorus pentasulphide until evolution of hydrogen sulphide has almost ceased. The product on crystallisation from acetic acid or alcohol has m.p. 98·5° C., and gives a colourless solution in concentrated sulphuric acid. (B) A solution of catechol in mono- or dichlorobenzene is heated with phosphorus pentasulphide. The product forms colourless needles, m.p. 156° C., from acetic acid, and shows a characteristic violet colour with concentrated sulphuric acid.—L. A. C.

Material resembling linoxyn. G.P. 327,913. *See* XIV.

IV.—COLOURING MATTERS AND DYES.

Java indigo plant; Conditions affecting the quality of the ——. *(Leaf yield and richness of the leaf in indigotin).* W. A. Davis. Agric. Res. Inst., Pusa, Indigo Pubn. No. 7, 1—33.

When indigo is grown with wheat as a cover crop, the indigo which follows the wheat grows slowly at first, probably owing to the removal of moisture from the soil by the wheat crop, but after the monsoon breaks it grows rapidly and forms a plant of exceptionally high quality containing a very high percentage of indigotin in the leaf. When the readily available nitrogen in the soil is high, the indigotin content of the plant is low, and although most nitrogenous manures give high yields of plant

per acre, the yield of dyestuff is low because of the low content of indigotin in the leaf. A cover crop improves the quality of the indigo by removing readily available nitrogen compounds from the soil. When the soil is poor in nitrogen, the plant is forced to utilise nitrogen fixed from the air by the nodule bacteria, and the activity of these organisms determines high indigotin content, the production of indican being due to the plant removing from the nodules nitrogen compounds which would be prejudicial to their continuous action. Favourable development of the nodules, which ensures a good growth of plant with a high indigotin content, is dependent on a low nitrogen content in the soil, a good supply of organic matter supplying carbohydrates, and a good supply of soluble phosphate in the soil. The very high yields obtained at Bunhar with mustard and linseed as cover crops indicate that, with proper manuring, indigo can be grown with a cover crop with great advantage, the poor results obtained hitherto in most cases being attributable to the depleted state of most plantation soils as regards phosphate and humus. —F. M. R.

6-Methylisatin. J. Bonnefoy and J. Martinet. Comptes rend., 1921, 172, 220—221.

m-TOLUIDINE condenses with mesoxalic esters to give esters of 6-methyldi-oxindole-3-carboxylic acid, which on saponification in presence of air give an alkali isatate, from which on acidifying the free isatin is obtained. Carbon bisulphide reacts with *m*-toluidine in the presence of hydrogen peroxide to give di-*m*-tolylthiourea, which with potassium cyanide and lead carbonate in aqueous alcohol yields hydrocyanodi-*m*-tolylcarbondi-imide, $CH_3.C_6H_4.NH.C(.CN):N.C_6H_4.CH_3$, which when heated at 40° C. in benzene with aluminium chloride for 4 hrs. gives 6-methylisatin-*m*-toluide. On boiling this with dilute hydrochloric acid 6-methylisatin is obtained, which when treated in acetic acid solution with the technical melt of phenylglycine gives methyl-6-indole-3-indole-2-indigo, m.p. 307°, dyeing wool and silk, and having a slight affinity for cotton.—W. G.

Isatin-5-sulphonic acid. J. Martinet and O. Dornier. Comptes rend., 1921, 172, 330—331.

WHEN isatin is dissolved in fuming sulphuric acid containing 20% SO_3 and the mixture is heated on a water bath for ½ hr., isatin-5-sulphonic acid is obtained, identical in every respect with that formed by the oxidation of sodium indigo-5.5'-disulphonate. The phenylhydrazone of the acid furnishes a lemon-yellow potassium salt, which dyes wool and silk a yellowish green. Potassium isatinsulphonate condenses with indoxyl in acetic acid solution to give indirubin, which in aqueous solution in an acid bath dyes wool and silk a violet shade.—W. G.

Nitro-derivatives of carbazine, phenoxazine, and thiodiphenylamine; Absorption spectra of certain ——. F. Kehrmann and H. Goldstein. Helv. Chim. Acta, 1921, 4, 26—31.

THE authors have investigated the absorption spectra of a number of nitro-compounds in alcoholic sodium hydroxide solution, in which they exhibit an intense characteristic coloration clearly differentiated from that of the solid compounds. This property is shown only by compounds possessing at least one nitro group in the para-position to the cyclic nitrogen atom. (*Cf.* J.C.S., Mar.) —T. H. P.

Colouring matters; Determination of the constitution of —— *from their absorption spectra.* F. Kehrmann and M. Sandoz. Helv. Chim. Acta, 1921, 4, 31—44. (*Cf.* J., 1920, 224 A.)

THE authors have examined the absorption spectra of monoamino-derivatives of methylphenazine, aposafranine and its isomerides and acetyl-compound, and of their mono-, di-, and tri-acid salts. From comparison of the spectra of the different compounds deductions are drawn as to the constitutions. (*Cf.* J.C.S., Mar.)—T. H. P.

Phthaleins. Csángi. *See* XXIII.

PATENTS.

Phthaleins; Manufacture of ——. O. Imray. From Monsanto Chemical Works. E.P. 157,030, 31.5.20.

AN anhydrous aromatic sulphonic acid, with or without zinc chloride, is used as the condensing agent. Thus, 100 pts. of phthalic anhydride is mixed with 200 pts. of phenol, solution is effected at 80° C., 200—250 pts. of, say, toluenesulphonic acid, or a mixture of 175 pts. of toluenesulphonic acid and 50 pts. of anhydrous zinc chloride, is added, and the mass is kept at a temperature below 140° C., preferably about 120° C., for 10—12 hrs. The product, which is particularly free from tarry by-products and from ortho-condensation products, is washed free from phenol and acid with water, and is finally purified by precipitation from sodium hydroxide solution in the usual way. The yield approximates to the theoretical.—G. F. M.

Monoarylaminoquinones; Manufacture of sulphonic acids of ——. M. Becke and W. and H. Suida. G.P. 326,511, 23.5.18. Addn. to 300,706 (J., 1920, 399 A).

THE desired compounds are produced by the interaction of 2 mols. of a quinone and 1 mol. of an aminoarylsulphonic acid in alcoholic solution. An aqueous solution of sodium sulphanilate (1 mol.) is added to an alcoholic solution of 1.4-benzoquinone (2 mols.) with stirring; after standing, the sodium salt of *p*-sulphophenylaminobenzoquinone separates as copper-coloured needles, which are readily soluble in water, slightly soluble in alcohol, and insoluble in ether, and dye wool an orange-brown shade from an acid bath. The monoarylaminoquinones serve as dyestuffs and for the production of mixed diaryldiaminoquinones, either as such or on the fibre.—L. A. C.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool; Action of water on ——. A. Reychler. Bull. Soc. Chim. Belg., 1920, 29, 291—300. Chem. Zentr., 1920, 92, II., 139.

ON heating wool to temperatures up to 150° C. with water or alkaline or acid solutions, under normal or increased pressure, acid or basic substances pass into solution which are precipitated by Fuchsin and form lakes with Eosin or Ponceau. The undissolved wool has lost the property of double refraction between crossed nicols, and can be powdered when dry. If wool is heated to 110°—120° C. with water, its elasticity is diminished, but it is still very tenacious, and its plastic properties at these temperatures are utilised in finishing processes. The relative insensitiveness to acids of methyl orange dyed on wool or silk, which is even more marked at high temperatures, is due to the combination of the indicator with a system which, although not markedly basic, is capable of combining with acid molecules.—L. A. C.

Cellulose in bast fibres. Y. Uyeda. J. Ind. Eng. Chem., 1921, 13, 141—143.

RENKER'S modification of Cross and Bevan's method (direct chlorination without preliminary treatment

with alkali) is recommended for the determination of cellulose in bast fibres. The function of pectin substances in bast fibres is discussed, and it is suggested that the cellulose of the hemp fibre has, in some degree, an oxycellulose structure.—W. P. S.

Cellulose mucilage J. E. Minor. J. Ind. Eng. Chem., 1921, 13, 131—133.

THE first stage in the decomposition of cellulose is the formation of mucilaginous soluble dextrins which are at once adsorbed by pure cellulose, yielding an aggregate termed hydrocellulose; mucilage differs from hydrocellulose in the larger proportion of soluble adsorbed dextrins present. The adsorbed dextrins act as catalysts in the hydrolysis of cellulose and complete hydrolysis leaves only soluble dextrins. Immersion in cold water produces slow hydrolysis of cellulose; hot water hastens hydrolysis and weakens adsorption, so that mucilaginous products are destroyed as rapidly as they are formed. Pulps with an original high copper value can be converted into mucilage by beating more easily than those with low copper values, owing to the larger amount of catalyst (dextrins) present; the copper value of bleached pulp can be increased by careful acid treatment previous to beating. Owing to its more colloidal state, cellulose mucilage decomposes a salt and adsorbs the metal ion more readily than does pure cellulose. The action of moisture or acid on cellulose aids dyeing by forming mucilage.—W. P. S.

Kraft [paper] pulps; Testing —— for strength. K. G. Wilen. Paper, Dec. 20, 1920, 15—17, 36.

KRAFT pulps (sulphate pulps) are used at present not only in the manufacture of pure "Kraft" paper, but also in the making of various other papers and board, and it is important to have a standard method for testing the pulp, especially when mixtures of pulp are used. The following method has been used by the author for three years:—25 g. of air-dried pulp is thoroughly broken up by forcing the pulp through a screen by means of a jet of water. The screened pulp is placed in a tared weighing cylinder, made up to 3 kg. with water, and transferred to a ball mill jar. The pulp is beaten for one hour in a ball mill; the beaten pulp is washed out, made up to 10 l., and three portions of 450 c.c. each are placed in a mill and made up to approximately 5 l. with water. After thoroughly stirring, the contents are poured on to a sheet machine. The sheets are pressed for a few seconds under hand pressure, dried at 180° F. (82° C.), and allowed to re-absorb moisture for 1 hr. Pieces 6″×6″ are then cut, and weighed to the nearest 0·05 g. The weight of the sheets is calculated to lb. per ream of 480 sheets, 24″×36″, *i.e.*, the commercial weight standard for "Kraft." The sheets are then tested on a Mullen tester. The average Mullen test multiplied by 100, and divided by the ream weight of the sheets, is the expression for the strength of the pulp.—J. C. K.

Wilkinite, a new loading material [for book paper]. S. D. Wells. Paper, Dec. 8, 1920, 19—21, 34.

WILKINITE, or "jelly rock," a highly colloidal clay, can be used as a substitute for English china clay as a filler for paper. The best results were obtained by using a mixture of the two minerals, viz., in the proportion of 30% of wilkinite and 70% of china clay. Wilkinite will remain in suspension for a long period, and has the power of holding in suspension English china clay up to at least twice the amount of wilkinite present. When a mixture of the two fillers is used, the greater the proportion of wilkinite, the greater the retention of filler by the paper.—J. C. K.

Maize cobs. La Forge. *See* XIX A.

PATENTS.

Silk; Process for degumming ——. O. Goldschmidt. E.P. 131,906, 28.8.19. Conv., 4.12.16.

SILK is degummed by subjecting it to the conjoint action of a peroxide or per-salt and soap solution. 60 g. of raw material is treated with a cold 0·1% solution of sodium peroxide, boiled, without removing the peroxide, in a 0·2% solution of soap for 5—10 mins., rinsed, and dried. Alternatively, the material is moistened with 20 kg. of 10% hydrogen peroxide solution and then boiled for 10—15 mins. in a solution containing 12 kg. of soap in 1400 kg. of water. The process is specially suitable for low-grade qualities of silk and the product dyes more readily and is more glossy than that obtained by the usual methods.—A. J. H.

Alkali-cellulose; Manufacture of matured —— and its instantaneous conversion into matured xanthate [viscose]. A. Thilmany. G.P. 328,035, 15.3.19.

CELLULOSE or the like is ground *in vacuo* at a raised temperature with an alkaline solution of about 15° B. (sp. gr. 1·116) until the alkali has increased by evaporation to a suitable strength, when the necessary quantity of carbon bisulphide is added to form a sufficiently matured xanthate.—L. A. C.

Cellulose solutions for spinning artificial threads or the like; Process of preparing durable cuprammonia ——. Glanzfäden A.-G. E.P. 145,035, 14.6.20. Conv., 12.10.17.

Washing and cleansing agents. G.P. 327,685. *See* XII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyeing; Co-ordination theory of valency in relation to adjective ——. G. T. Morgan. J. Soc. Dyers and Col., 1921, 37, 43—47.

ACCORDING to Werner's co-ordination theory, the chemical affinity of an atom is divisible in a great variety of ways, depending on the circumstances of chemical combination, into a variable number of valencies of unequal intensities, which are distributed uniformly over the spherical surface of the atom. The chemical elements do not all give rise to equally stable co-ordination complexes, and in regard to this difference the volume of the atomic sphere plays an important part. The metals which give rise to stable co-ordination complexes are those which yield the lakes produced in adjective dyeing with acid mordant colours. Certain compounds and compound radicles, termed chelate groups, take up two positions round the central atom and function as adjective dyes on suitably mordanted material. The lakes or chelate complexes of a number of dyes are reviewed, and it is concluded that the co-ordination theory of valency suffices not only to explain and correlate known facts, but will serve as a guiding principle in future investigations on the theory and practice of adjective dyeing.—F. M. R.

Indigo vat; Influence of the degree of dispersion of the dyestuff in the —— on the shade produced. M. Freiberger. Textilber., 1921, 2, 84—86.

THE colour of a fabric dyed with indigo is due to indigo deposited within the fibre, this being greyish-blue in colour and very fast to rubbing; to a cellulose-dyestuff compound of indigo-blue colour, fast to rubbing; to crystalline indigo deposited near the surface of the fibre, violet-blue in colour and less

fast to soap and rubbing; and to re-oxidised indigo attached to the surface of the fibre, bluish-grey in colour and not fast to soap and rubbing. The degree of dispersion of the indigo in the vat determines the condition in which it dyes the fibre. Fast dyeings result when the indigo is in a highly dispersed state, and this is obtained by increasing the temperature and dilution of the dye liquor. Fugitive dyeings result when the dye liquor contains indigo in a highly aggregated state, due, *e.g.*, to the presence of an excess of lime or glue or an insufficiency of caustic soda. The sodium salt of indigo white forms a colloidal solution of a higher degree of dispersion and enters the fibre more freely than the calcium salt, and it also serves as a carrier of re-oxidised indigo.—A. J. H.

Staple fibre fabrics; Dyeing and finishing of ——. A. Winter. Textilber., 1921, 2, 40—41.

Staple-fibre fabrics (*cf.* J., 1919, 281 A) containing vegetable fibres only are prepared for dyeing by the usual methods except that bleaching is preferably carried out by immersing the fabric for 20—30 mins. at 20° C. in a 1½% solution of sodium hypochlorite, lightly rinsing, immersing in hydrochloric acid of 1° B. (sp. gr. 1·007), washing, and treating with an "antichlor." Fabrics containing animal fibres are bleached with hydrogen peroxide, sodium peroxide, or sodium perborate solutions, rinsed, and soured in formic acid. Dyeing may be carried out in the usual manner with direct, sulphur, and vat dyestuffs. Fabrics used for clothing generally contain wool and are dyed by the usual methods for cotton-wool unions, very fast shades being obtained by dyeing the wool with chrome-mordant dyes and the cotton with sulphur dyes, glue, glucose, or bisulphite being added to the dye-bath to preserve the wool from injury. Shot effects may be obtained. After dyeing the wool is invariably treated with formic acid to restore its pleasing "handle." The finishing processes are dependent on the composition of the fabric, but are similar to those usually adopted. 5—6% of Naphthylamine Black EFF (Cassella) in the presence of 4—5% of sulphuric or formic acid gives a full shade on wool and a light grey on staple-fibre, so that it is very useful in testing staple-fibre fabrics for the presence of animal fibres.—A. J. H.

Silk; Dyeing —— with indanthrene colours. H. E. Schroers. Textilber., 1921, 2, 38—40.

For *Anthraflavon G.C.; Indanthrene Scarlet G.S. pdr.; Indanthrene Gold Orange R and R.R.T.; *Indanthrene Violet R extra, RR extra, RT and B extra; Indanthrene Blue G.C. and GCD; Indanthrene Blue-green B; Indanthrene Red-brown R; *Indanthrene Green B; Indanthrene Grey B and 3B; *Indanthrene Olive G. pdr.; and *Indanthrene Brown B conc., dyeing is carried out with 10 kg. of material for 1 hr. at 40° C. in a dye-bath containing 250 l. of liquor, 3 l. of caustic soda of 40° B. (sp. gr. 1·386), 500—1500 g. of hydrosulphite pdr. conc., 1—40% of dyestuff, 1200 g. of glycerin, and 5000 g. of "cell-pitch" 50%. For *Anthraflavon GC; *Indanthrene Gold Orange G; Indanthrene Orange RT; Indanthrene Copper R; Indanthrene Red-brown R; Indanthrene Red G. and R; *Indanthrene Rose B; Indanthrene Bordeaux B and B extra; Indanthrene Violet R extra, RR extra, and RT; Indanthrene Blue GCD; *Indanthrene Green B; Indanthrene Grey B and 3B; *Indanthrene Olive G pdr., and *Indanthrene Brown B conc., the alkali content of the dye-bath is reduced to 750 c.c. of caustic soda of 40° B and the amount of glycerin is increased to 1250 g. During dyeing the temperature of the bath is raised to 40° C. Dyestuffs marked * are used in a cold or lukewarm dye-bath. After dyeing the material is left to oxidise in the air (drying should be avoided), allowed to hang over-night, well washed in water, treated in a boiling solution of soft soap, and brightened with formic acid. A firmer "handle" is obtained if the silk is treated before soaping in a 0·6% solution of tannic acid, and fixed with tartar emetic. Silk having a soft "handle" and suitable for embroidery is obtained by treating the material, after brightening, in a neutral bath containing a 0·3% solution of Marseilles soap and some olive oil emulsion. In dyeing with gold orange dyes, oxidation with air is supplemented by working the dyed silk for 30 mins. in an acid bath containing 750 g. of sodium perborate and 1 l. of 30% acetic acid (or its equivalent of formic acid) per 250 l. of liquor, the temperature being increased from 40° to 70° C. The shades produced with the above-named dyes are very fast to washing, acids, bleeding, hydrogen peroxide, and light except in the following cases:—Indanthrene Olive G pdr. and Brown B conc. are only moderately fast to hydrogen peroxide; Idanthrene Orange RT, Copper R, Rose B, and Olive G pdr. are not fast to light; and Indanthrene Gold Orange R and RT, Violet RT and B extra, and Red-brown R are only moderately fast to light. In certain cases useful shades may be obtained by treating the dyed material with an acid and sodium nitrite.
—A. J. H.

Detergents [for fabrics]; Determination of the washing and cleaning action of ——. P. Heermann. Textilber., 1921, 2, 37—38, 61—62.

Fabric is artificially soiled by immersion in a 0·5% solution of 20% colloidal indigo paste, pressed until it contains its own weight of liquor, and dried at the ordinary temperature. It may be further similarly treated with starch paste and a solution of machine oil in benzene or ether. Samples of the soiled fabric (10 g.) are cleansed by squeezing 20 times at room temperature in 250 c.c. of water, of 0·4% solution of sodium carbonate, of 0·4% solution of soap powder, or of a solution containing 0·125% of palm oil soap (60% fat) and 0·075% of sodium carbonate. The liquor, contained in a porcelain dish, is heated on the water-bath during 10—15 mins. to 50° C. and the fabric again squeezed 20 times. The dish is then removed from the water-bath, and after each of three intervals of 15 mins. the fabric is squeezed 20 times (100 times in all), washed in lukewarm water till no more colour is extracted, washed in cold running water, dried, and pressed with a hot iron (sublimation of the indigo must be avoided). Washing must always be carried out with distilled water. The liquids mentioned have an increasing cleansing power in the order given, and for the last this is considered to be 100. Samples of the artificially soiled fabric are cleansed, in the same manner, in solutions of the detergent under examination and then compared with the standards. The degree to which a fabric has been cleansed is judged from its colour, and not from its loss in weight. The results obtained by this method agree with those obtained in large-scale practice.—A. J. H.

Patents.

Discharge printing. C. H. Boehringer Sohn. G.P. 328,817, 9.10.17.

The addition of salts of bile acids, *e.g.*, cholic acid, increases the solubility of the discharge products and facilitates their removal from the fibre.
—L. A. C.

Textile goods; Apparatus for the treatment of —— in hank form by means of circulating liquids. E. Nägelin. U.S.P. 1,367,494, 1.2.21. Appl., 26.4.20.

The apparatus contains a device by means of which liquid is supplied under slight pressure to a number of horizontal hank carriers. The carriers are tubes perforated in their upper side only and mounted

in a bearing at one end, so that they can be rotated; the liquid flows from the perforations down along the hanks or skeins.—A. J. H.

Fabrics; Production of coloured ornamental designs upon textile —— by machine embroidery and the application of liquid dyes or colours. Straub and Co. E.P. 157,682, 10.6.20. Conv., 1.3.20.

A stencil of paper, celluloid, or other material is pressed against the fabric, preferably while in the frame of the embroidery machine, either before, during, or after the embroidery, and is sprayed with a viscous solution of the dyestuff.—A. J. H.

Cleansing [fabrics etc.] with alkali salts of protalbinic and lysalbinic acids; Method of ——. C. Bennert, Assr. to The Chemical Foundation, Inc. U.S.P. 1,367,007, 1.2.21. Appl., 27.12.15.

See G.P. 311,542 of 1915; J., 1919, 625 A.

Bleaching, dyeing, or the like; [Wire] foundations for supporting sliver, roving, yarn, or the like during the process of ——. H. Winslow. E.P. 157,507, 20.9.19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid manufacture; Use of ammonia oxidation units for ——. W. Wyld. Chem. Age, 1921, 4, 150—151.

In connexion with the employment of ammonia oxidation units for sulphuric acid manufacture, some details of plant design are given. Loss of ammonia from storage tanks is prevented by connecting the vent with a water-scrubber. Access to the platinum gauges is afforded by providing a removable cover with mica window in the converter. To economise platinum, two layers of wire of 0·0125 in. diam. and 120- to 150-mesh may be used instead of four layers of 0·065 in. diameter and 80-mesh. Special precautions must be taken in fixing the asbestos washers when introducing the catalyst, to prevent disintegration of the asbestos, and lead piping should be used, instead of iron, from the still head to converter, to avoid deposition of rust on the catalyst. The efficiency of the oxidation units is easily maintained at 90%, and the production is 1·5 tons of nitric acid per sq. ft. of catalyst per 24 hrs.—W. J. W.

Sulphur dioxide and sulphur trioxide; Determination of —— in burner gases by means of the gas absorption flask. H. Krull. Papierfabr., 1921, 19, 93—95.

The author gives results of his analyses of sulphur gases by means of a modified Reich gas absorption flask (Chem.-Zeit., 1920, 43, 167). The estimation is more rapidly made than with the Orsat apparatus, and comparative results showed an average difference of 2·2%.—W. J. W.

Hydrochloric acid; Utilisation of ——. H. Hackl. Chem.-Zeit., 1921, 45, 149—150.

It is suggested that weak hydrochloric acid be employed for the treatment of crude phosphate, instead of the usual sulphuric acid, dicalcium phosphate being then precipitated by means of milk of lime. This would permit of the sulphuric acid from the cheaper native pyrites being used for the production of the hydrochloric acid and sodium sulphate instead of for superphosphate manufacture as at present.—A. de W.

Ammonia; Microchemical identification of gaseous —— as hexamethylenetetramine picrate. C. Kollo and V. Teodossiu. Bul. Soc. Chim. România, 1920, 2, 100—102.

When a drop of a 40% solution of formaldehyde saturated first with picric acid and then with hexamethylenetetramine picrate is exposed on a microscope slide in an atmosphere containing a trace of ammonia, characteristic microscopic crystals of hexamethylenetetramine picrate are deposited. —W. G.

Potassium compounds; Measurement of the vapour pressure of certain ——. D. D. Jackson and J. J. Morgan. J. Ind. Eng. Chem., 1921, 13, 110—118.

As determined by the Von Wartenberg method (Z. anorg. Chem., 1912, 79, 76; Z. Elektrochem., 1913, 19, 482) the vapour pressures of potassium compounds were found to be as follows, the results being given in mm. of mercury:—Hydroxide, 8 at 795° C.; chloride, 1·54 at 801° C., 8·33 at 948° C., 24·1 at 1044° C.; oxide in carbonate, 1·68 at 970° C., 5·0 at 1130° C.; sulphate, 0·4 at 1130° C.; natural silicates, 0 at 1335° C. From the results obtained with potassium chloride together with the b. pt. of this compound as given by Bergstrom (Med. Finska Kemistsamf., 1915, 24, 2), the Nernst vapour pressure formula for potassium chloride has been calculated to be: $\log P = -5326/T + 1{\cdot}75 \log T + 0{\cdot}000511T - 0{\cdot}7064$.—W. P. S.

Iodides; Determination of —— in the presence of iodates. V. Thüringer. Bul. Soc. Chim. România, 1920, 2, 73—77.

For the quantitative analysis of a mixture of iodides and iodates, the iodate is first estimated by adding 0·2 g. of the substance dissolved in water to a solution of 1·5 g. of potassium iodide acidified with sulphuric acid and titrating the liberated iodine with $N/10$ sodium thiosulphate. To another 0·2 g. of the substance dissolved in water a known volume of $N/60$ iodic acid is added, the mixture is acidified with sulphuric acid and boiled until the whole of the liberated iodine has disappeared. The solution is cooled, an excess of potassium iodide is added, and the iodine liberated titrated with $N/10$ sodium thiosulphate. From these two titrations the iodide present in the original mixture can be calculated.—W. G.

Uranium; Preparation of pure compounds of ——. E. Wilke-Dörfurt. Wiss. Veröffentl. Siemens-Konzern, 1920, 1, 143—146. Chem. Zentr., 1921, 92, I., 170—171.

The uranium oxide obtained from cleveite by solution of the mineral in nitric acid, followed by removal of the rare earths and thorium by oxalic acid, and of the heavy metals by hydrogen sulphide and ammonium sulphide in the usual way, was found to contain small amounts of alkali, probably as uranate. This was removed by precipitation of the uranium as disulphide instead of as uranyl sulphide. The process was repeated and the sulphide dissolved in hydrochloric acid, the solution treated with ammonia, and the precipitate dissolved in nitric acid. The oxide obtained from the nitrate crystallised from this solution showed no trace of alkali when examined in the spectroscope. Recrystallisation of uranyl nitrate from ether does not give a product free from alkali.—A. R. P.

Topochemical reactions. Formation of carbon at contact substances. V. Kohlschütter and A. Nägeli. Helv. Chim. Acta, 1921, 4, 45—76. (*Cf.* J., 1919, 174 A, 221 A.)

The structure of the carbon deposited when carbon monoxide is passed through a tube containing a heated metal is influenced by the character of the

contact metal, the temperature of the reaction, and the state of subdivision of the metal. Cobalt yields a graphitic carbon of markedly different nature from that obtained with iron or nickel; the similarity of the results obtained with electrolytic and powdered cobalt indicates a specific action of the metal. Neither with reduced nor with powdered iron is the formation of graphite favoured by raising the temperature of the reaction; increase in the degree of subdivision of the metal does, however, favour the development of the graphitic type. In comparison with the carbon of electrolytic deposits, which exhibits strongly graphitic properties, that deposited on metallic powders, with the exception of powdered cobalt, more nearly resembles soot in appearance and behaviour. The view that a continuous gradation exists between the different forms of carbon is thus supported, and it is further evident that, under similar external conditions, the formation of one or another product may be obtained from one and the same chemical reaction merely by alteration of the structure of the locus of the reaction.—T. H. P.

Carbon; Fusion of ——. E. Ryschkewitsch. Z. Elektrochem., 1921, 27, 57—64.

A RESISTANCE furnace is described consisting essentially of a carbon box, 10 cm. square, with open ends 7 cm. square, into which fit the carbon electrodes. The inside of the box is filled with graphite. A current of 500—560 amps. was passed for 8—12 hrs. At the end of this time the electrode ends and the contents of the box were found to be pure graphite, at least 99·9%, and the electrode ends showed, when examined microscopically, unmistakable signs of having been in the molten condition. At ordinary pressures the temperature range over which carbon can remain in the fluid condition is very restricted, and this accounts for the difficulty of obtaining evidence of melting.

Point discharge in nitrogen. Pirani and Lax. *See* XI.

Nitric acid. Winkler. *See* XXIII.

PATENTS.

Sulphuric acid; Manufacture of ——. J. H. Brown. U.S.P. 1,365,964, 18.1.21. Appl., 16.7.18.

IN a sulphuric acid chamber plant means are provided for washing the burner gases, and for reheating the washed gases previous to oxidation.

—W. J. W.

Sulphur trioxide; Making —— [*by the contact process*] *and apparatus therefor.* H. M. Weber, Assr. to The Ellis-Foster Co. U.S.P. 1,366,439, 25.1.21. Appl., 8.2.17.

THE relative speed of the gases in the inner and outer sections of the catalytic members is adjusted by varying the cross-section, porosity, and depth of the members.—C. I.

Hydrochloric acid free from arsenic; Production of ——. H. Frischer. G.P. 326,618, 21.2.19.

HYDROCHLORIC acid gas containing arsenic compounds is treated with hydriodic acid gas or iodides whereby insoluble arsenic tri-iodide is formed.—A. R. P.

Copper sulphate; Manufacture of ——. R. E. Bea. E.P. 147,689, 8.7.20. Conv., 3.8.17.

IN a vessel containing dilute sulphuric acid are suspended a perforated receptacle containing copper waste into which dips a leaden anode, and a porous pot filled with dilute sulphuric acid in which hangs the leaden cathode. Deposition of copper on the latter is avoided by this arrangement, and copper sulphate crystallises in the vessel.—W. J. W.

***Thorium compounds* [*double metaphosphate and sulphate of thorium*]; *Manufacture of insoluble* ——.** **H. Wade. From Lindsay Light Co. E.P. 156,892, 11.10.19.**

A DOUBLE metaphosphate and sulphate of thorium, $Th(PO_3)_2SO_4$, of the same composition, but purer than the compound obtained by heating a natural mineral containing thorium and phosphates, such as monazite sand, with sulphuric acid at a high temperature (*cf.* U.S.P. 1,323,735; J., 1920, 517 A) is prepared in the form of white acicular crystals by dissolving 120 g. of thorium sulphate, $Th(SO_4)_2$, $8H_2O$, in 50 c.c. of 80% phosphoric acid and heating for 10 hrs. at 280° C. Water and sulphuric acid fumes are evolved and the product forms a nearly solid crystalline mass, insoluble in water or in dilute acids. The same substance is also obtained by heating thorium phosphate with an equal weight of sulphuric acid, preferably in presence of 20—40% of phosphoric acid, for 10 hrs. above 260° C.

—G. F. M.

Thorium nitrate; Method of manufacturing ——. H. N. McCoy, Assr. to Lindsay Light Co. U.S.P. 1,366,128, 18.1.21. Appl., 30.12.18.

As a step in the manufacture of thorium nitrate, monazite sand is treated with concentrated sulphuric acid, and the insoluble thorium compound produced, after removal of soluble impurities, is converted into thorium hydroxide.—W. J. W.

Lead sulphate; Process of making —— *direct from lead sulphide ores.* P. A. Mackay. E.P. 157,554, 18.10.19.

FINELY-GROUND galena, substantially free from zinc, is added gradually, with constant stirring, to an excess of sulphuric acid containing about 20% of free sulphur trioxide, whereby a vigorous exothermic reaction takes place and substantially pure lead sulphate is produced. The excess of acid is recovered by diluting the mass with water, allowing the precipitate to settle, and decanting the clear liquid. The lead sulphate is suitable for use as a pigment.—A. R. P.

Ammonium sulphate; Apparatus and process for the recovery of ——. J. Becker, Assr. to The Koppers Co. U.S.P. 1,366,111, 18.1.21. Appl., 18.6.17.

MOIST gases, freed from tar, are passed through a saturation bath in which ammonia is absorbed, and are then superheated and passed through another part of the bath, thus promoting evaporation and precipitation of ammonium sulphate.—W. J. W.

Ammonium chloride; Manufacture of solid —— *from hydrochloric acid gas and ammonia.* A.-G. für Anilin-Fabr. G.P. 326,619, 14.2.9.

HYDROCHLORIC acid gas and ammonia are allowed to react in the presence of a fine spray of water in such quantity that it is practically completely vaporised by the heat of the reaction, which is thereby enabled to go on to completion.—A. R. P.

Ammonium chloride; Method of producing —— *from fuels.* W. Ostwald, Assr. to The Chemical Foundation, Inc. U.S.P. 1,367,082, 1.2.21. Appl., 23.2.17.

THE nitrogen in fuels is obtained as ammonium chloride by injecting into the burning fuel an aqueous solution from which chlorine is evolved.

—C. I.

Ammonia; Process for recovering liquid —— *from moist ammonia vapours.* "Metan" Spółka z Ograniczona Odp. we Lwowle. G.P. 326,929, 13.6.18. Conv., 8.8.17.

THE vapours are cooled by passing them through a column and then through a cooler, in each of which

an increase of pressure, somewhat greater than the vapour pressure of the ammonia at the temperature of the cooler, is produced, preferably by passing into the apparatus highly compressed water-vapour.—A. R. P.

Metallic halides; Process of making ——. C. M. Alexander. U.S.P. 1,366,626, 25.1.21. Appl., 9.10.19.

A PULVERISED metal-bearing material, fuel, air, and a halogen are injected together into a combustion and reaction chamber.—C. I.

Ferrous oxide; Process of producing ——. A. J. MacDougall, Assr. to H. C. Bigbird, J. G. Rowe, and R. H. Bennett. U.S.P. 1,367,409, 1.2.21. Appl., 21.8.20.

IRON is treated in an electrolytic cell with the acid product of the electrolysis of a salt solution, and the ferrous salt thus formed is decomposed by the alkaline product of electrolysis.—C. I.

Potassium nitrate and mixed salts containing potassium and nitrogen; Manufacture of ——. Badische Anilin und Soda Fabr. G.P. 306,334, 11.3.16.

AMMONIUM nitrate and potassium chloride are dissolved in hot water; potassium nitrate crystallises on cooling, and a mixed salt, suitable for use as a fertiliser, is separated from the mother liquor either by evaporation to dryness or by fractional crystallisation. If the potassium chloride employed contains much sodium chloride, the quantity of water is so adjusted that the greater part of the sodium chloride remains undissolved in the hot solution.—L. A. C.

Magnesium; Manufacture of a double salt for use in the electrolytic production of ——. Aluminium- und Magnesium-Fabr. A.-G. G.P. 328,413, 3.12.15.

THE mixture of salts obtained as by-product in the electrolytic production of magnesium from carnallite is mixed with the end liquor from the production of potassium chloride, the solution is partially evaporated, and is allowed to crystallise. The double salt $MgCl_2,KCl,6H_2O$ crystallises out together with sodium chloride, and the water of crystallisation is eliminated by heat. The fused salt, $MgCl_2,KCl,NaCl$ is allowd to cool in a vessel of inverted conical shape, whereby impurities collect in the apex.—L. A. C.

Hydrogen sulphide; Production of —— *from sulphates.* Apparate-Vertriebs-Ges.m.b.H. G.P. 306,352, 20.11.17. Addn. to 304,231 (J., 1920, 364 A).

As a reducing agent for sulphates, carbon monoxide, alone or mixed with hydrogen and hydrocarbons, may be employed instead of gaseous hydrocarbons.—W. J. W.

Calcium or barium sulphide; Manufacture of —— *from calcium or barium sulphate.* Metallbank und Metallurgische Ges. A.-G. G.P. 307,612, 3.3.17.

A MIXTURE of the sulphate with coal or the like is made into small lumps before heating in a rotary tube furnace.—L. A. C.

Nitrogen compounds; Production of ——. "Azot"-Ges.m.b.H. G.P. 309,154, 4.5.18.

ATMOSPHERIC air, or other mixture of oxygen and nitrogen, mixed with steam, is forced as a blast over or against strongly heated metals, such as platinum, nickel, or iron, or other heat-resisting bodies. Ammonium nitrite may thus be produced by blowing a mixture of air and steam over heated platinum gauze.—W. J. W.

Alkali peroxides; Preparation of dry, hydrated ——. Drägerwerk H. u. B. Dräger. G.P. 310,671, 6.12.16.

HYDRATION of alkali peroxides is effected in a liquid medium which is immiscible with water and unaffected by the reacting materials (water and alkali peroxide), and the liquid is afterwards separated. Petroleum, ethylene chloride, and the like may be employed.—W. J. W.

Manganese acetate; Production of —— *from higher oxides of manganese.* Konsortium für Elektrochem. Ind. G.m.b.H. G.P. 327,086, 30.3.19.

A MIXTURE of acetic acid and acetaldehyde is allowed to react with the higher oxides of manganese. Addition of an alkali or alkaline-earth acetate accelerates the reaction.—A. R. P.

Potassium ferricyanide; Manufacture of —— *from calcium potassium ferrocyanide.* C. Giesen. G.P. 327,289, 18.1.20.

CALCIUM potassium ferrocyanide is suspended in water and, either before or after oxidation with chlorine, the requisite quantity of potassium chloride is added to replace the calcium. Potassium ferricyanide crystallises on evaporating the solution and is thus easily separated from the calcium chloride.—L. A. C.

Calcium chloride; Manufacture of fused ——. A. Riedel. G.P. 327,867, 16.5.17.

HYDROCHLORIC acid gas, or waste gas containing it, is led through a tower packed with lumps of calcium carbonate. The calcium chloride solution formed is concentrated by the heat of reaction as it passes down the tower, and the liquor which collects at the bottom solidifies on cooling.—L. A. C.

Hydrogen; Production of —— *by alternate oxidation and reduction of iron.* W. Paternoster. G.P. 328,691, 8.3.18.

IN a hydrogen generator in which the contact material is arranged in layers, steam and other gases are introduced for oxidation and reduction purposes respectively in the form of divided streams, the combined cross-sections of which are greater than that of the part of the apparatus through which they pass.—W. J. W.

Hydrogen peroxide; Processes for the production of ——. L'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. E.P. 141,758, 17.4.20. Conv., 11.5.14.

VIII.—GLASS; CERAMICS.

Screens for optical pyrometry. Forsythe. See XXIII.

PATENTS.

Glass. M. A. Smith, Assr. to McKee Glass Co. U.S.P. 1,365,797, 18.1.21. Appl., 15.7.18.

A GLASS having a low coefficient of expansion and high resistance to changes of temperature is made from a batch consisting of a preponderance of silica, smaller amounts of boric oxide, alumina, sodium nitrate, and sodium carbonate, and still smaller amounts of calcium carbonate and arsenic trioxide.—H. S. H.

White clouded glasses, enamels, and glazes; Process for manufacture of ——. E. Rietz. U.S.P. 1,366,101, 18.1.21. Appl., 22.8.19.

IN the production of white clouded glass, enamels, and glazes, unpurified clouding material is used, together with sufficient material containing fluorine to prevent discoloration.—H. S. H.

Silica; Method and apparatus for washing and treating ——. R. H. Moore. U.S.P. 1,366,582, 25.1.21. Appl., 29.8.17.

SILICA is passed through a classifier consisting of a series of tanks each with a sorting compartment, provided with an overflow, stirring mechanism, and an endless conveyor placed at an angle, with its lower end in the compartment and its upper end above one side of the stirring mechanism in the next compartment. Means are provided for washing the coarse sand as it is conveyed from one compartment to the next.—A. B. S.

Cement suitable for dental purposes; Preparation of a ——. C. Jacobsen. G.P. 329,005, 24.10.19.

THE product is obtained by precipitation from a solution of suitable materials dissolved in the form of their salts etc. For example, the product obtained by precipitation with ammonia of a solution of alum, zinc sulphate, phosphoric acid, and water-glass is washed, dried, calcined, powdered, and sifted. It is three times denser than the corresponding mixture of powdered aluminium silicate, zinc silicate, zinc phosphate, and alumina, and the cement is tougher.—G. F. M.

Glass-furnace. A. F. Peeters, Assr. to Naaml. Vennoots. Glasfabriek Leerdam. U.S.P. 1,366,745, 25.1.21. Appl., 4.4.18.

IX.—BUILDING MATERIALS.

Concrete; Effect of tannic acid on the strength of ——. D. A. Abrams. Proc. Amer. Soc. for Testing Materials, 1920, **20**, Pt. I. Bull 7, Structural Materials Res. Lab., Lewis Inst., Chicago.

ABOUT 2000 tests were made on samples of concrete prepared from aggregates containing up to 0·4% of tannic acid, the latter being applied as a surface coating and regarded as being generally typical of the organic impurities existing in natural sands. The mixes varied from 1:5 to 1:2, the size of aggregate from fine sand to ¾-inch graded material, and the age of the test-pieces (stored in damp sand) from 7 days to 2 years. For all percentages of tannic acid in the aggregate the strength of the concrete was reduced for all mixes and ages. In some cases the reduction amounted to 50% when the aggregates contained 0·1% of tannic acid, but the weakening effect of the latter was less marked as the percentage increased beyond this figure. Lean mixtures were more affected by tannic acid than rich ones, and those containing the finer were less affected than those containing the coarser aggregates. The reduction in strength of the concrete was found to be a function of the concentration of tannic acid in the mixing water; the results indicated that wetter mixes would be less affected than drier ones by the presence of organic impurities. The strength of the 7- and 28-day specimens was reduced to a greater extent by tannic acid than that of the 1- and 2-year specimens; some of the 1:5 mixes, containing the finer sands and the higher percentages of tannic acid, disintegrated before the time of test. The results are regarded as indicating the fundamental dependence of the strength of concrete on the quantity of mixing water as expressed by the water-ratio.—W. E. F. P.

PATENTS.

Wood; Process for drying ——. Holzbearbeitungsges. m.b.H., K. Haring, and E. Voit. E.P. 141,727, 14.4.20. Conv., 28.3.19.

THE wood is exposed uniformly on all sides to a source of heat radiation and at the shortest possible distance from it, the temperature being preferably low at first, *e.g.*, 30°—40° C., and then raised by stages to about 90° C. It is possible to interrupt the operation after drying at the lower temperatures and to proceed later with the expulsion of the water from the inner layers at the higher temperatures. It is advantageous to conduct the drying operations in a vacuum.—H. S. H.

Wood; Method and apparatus for transforming [and colouring] ——. H. F. Weiss, Assr. to C. F. Burgess Laboratories. U.S.P. 1,366,225, 18.1.21. Appl., 6.10.17.

WOOD is heated to 380°—420° F. (194°—215° C.) in circulating air for a sufficient time to transform it into an uniformly coloured, less hygroscopic product.—A. B. S.

Cement and by-products; Process of making ——. S. B. Newberry. U.S.P. 1,366,479, 25.1.21. Appl., 1.6.20.

CEMENT clinker is made by heating a finely ground mixture of raw cement materials and carbonaceous fuel. The condensable products volatilised from the fuel are collected and recovered, and the heating of the clinker is effected by gas volatilised from the fuel and by the combustion of the fixed carbon.
—A. B. S.

Kiln; Portland cement and calcining ——. *Cement kiln.* J. Nelson. U.S.P. (A) 1,366,585 and (B) 1,366,586, 25.1.21. Appl., 19.7.19 and 24.3.20.

(A) A SHAFT-KILN with ring gas-burners fixed internally is covered by a hood through which the kiln can be fed by a conveyor. Across the bottom of the hood is a screen and a stirring and distributing blade rotated by an electric motor, so that the charge is uniformly distributed over the contents of the kiln. (B) In a similar kiln having spaced annular walls, a downdraught chamber communicates with the lower part of the space between the annular walls, this space being fitted with baffle plates so that it forms a spiral updraught flue having its outlet near the top of the kiln.—A. B. S.

Cement; Manufacture of porous ——. A. Grosche. G.P. 327,907, 9.5.19.

A SUITABLE powdered metal, *e.g.*, 1% of zinc dust, is added to the dry cement, which is then mixed with a solution of a compound, *e.g.*, a 2% solution of calcium chloride or sodium hydroxide, which reacts with the metal, at the temperature generated by the heat of reaction, to liberate gas bubbles and thus render the cement porous.—L. A. C.

Artificial stone; Manufacture of ——. M. E. Leblanc and K. Gerson. G.P. 327,906, 13.2.14.

A mixture of bauxite, or residues from the manufacture of aluminium, and 10—15% of slaked fat lime or hydraulic lime, with or without the addition of quartz sand, is worked up according to the usual method for lime-sand bricks, yielding stone showing a high resistance to pressure and atmospheric influences such as frost.—L. A. C.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Sulphur; Estimation of —— *in wrought iron, steel, and cast iron.* A. Cartoceti. Giorn. Chim. Ind. Appl., 1920, 2, 682—686.

The following method is recommended as a check on the more rapid methods used in industrial laboratories for estimating sulphur in iron or steel. 10 g. of the sample, in filings or turnings, is mixed with 2 g. of potassium chlorate and the mixture treated in a porcelain dish with 100 c.c. of concentrated nitric acid containing 2 c.c. of bromine; the acid is added slowly and intense heating of the liquid avoided by placing the dish in cold water. When evolution of gas ceases, 20 c.c. of concentrated hydrochloric acid is added and the solution evaporated to dryness on a sand-bath. The sand is then removed from the bath and the dish heated on the metal tray to redness to decompose nitrates and complete the oxidation. The cold residue is again evaporated with 50 c.c. of concentrated hydrochloric acid, the residue being then evaporated with another 50 c.c. of the acid to a syrup, which is diluted with a little water and allowed to cool. The cold liquid is poured, with continual shaking, into a 1-litre measuring flask containing 300 c.c. of 10% ammonia solution, the dish being also rinsed into the flask. When cold the solution is made up to volume, mixed, the voluminous precipitate allowed to settle, and the liquid filtered through a dry filter. 500 c.c. of the filtrate is evaporated to about 150 c.c. and precipitated at the boiling point with 20 c.c. of boiling 10% barium chloride solution, which is added all at once and with stirring. It is necessary to carry out a blank estimation with the reagents.—T. H. P.

Chromium in steels; Determination of small quantities of ——. B. S. Evans. Analyst, 1921, 46, 38—42.

Four g. of the sample is dissolved by heating with 30 c.c. of sulphuric acid (1:3) and 20 c.c. of water, 10 c.c. of nitric acid is added, and the solution boiled to expel nitrous fumes; 25 g. of ammonium phosphate and 250 c.c. of water are then added, the boiling solution is treated with a slight excess of permanganate, boiled for a further 15 mins., and then poured into 120 c.c. of 20% sodium hydroxide solution which has been heated to boiling, treated with an excess of permanganate and then with 10 c.c. of 5% manganese sulphate solution. The resulting mixture, if acid in reaction, is rendered strongly alkaline with sodium hydroxide, cooled, acidified with acetic acid, diluted to 500 c.c., and filtered. In the absence of nickel and cobalt, the chromium is determined directly, by comparing the colour of the filtrate with that of a standard bichromate solution in the presence of sulphuric acid; if nickel and cobalt are present, 100 c.c. of the filtrate is boiled, treated with sodium hydroxide until a precipitate separates, cooled, filtered, the filtrate acidified with sulphuric acid, and the chromium then determined colorimetrically as described.—W. P. S.

Molybdenum steel; Manufacture of ——. Pokorny. Z. Metallkunde, 1920, 12, 238—239. Chem. Zentr., 1921, 92, II., 114—115.

On account of the readiness with which molybdenum oxidises and the easy solubility of the oxide in the solid metal, the best way of adding molybdenum to steel is as a ferro-molybdenum alloy containing about 45% Mo, which has been melted electrically and carefully deoxidised. The best deoxidisers for such steels are titanium and vanadium, as they act also as nitrogen scavengers, their nitrides being readily volatilised, whereas when aluminium and silicon are used, difficultly volatile nitrides of molybdenum are formed. The double iron-molybdenum carbide is very sparingly soluble in molten iron; it is, therefore, advisable in preparing molybdenum steels to add to a bath low in carbon the required amount of a low-carbon ferro-molybdenum and then to carburise the metal up to the required carbon content.

—A. R. P.

Copper; Metallographic investigation of electrolytically deposited bright ——. G. Grube and V. Reusz. Z. Elektrochem., 1921, 27, 45—52.

Smooth, mirror-like deposits of copper were obtained by the method originally described by Müller and Bahntje (J., 1906, 484). The electrolyte consisted of a 0·5 molar solution of copper sulphate, acidified with sulphuric acid to give a $N/100$ solution of H_2SO_4, with the addition of 10 c.c. of a 1% gelatin solution to 200 c.c. of the copper sulphate solution. The copper electrodes were each 6·5 by 6·0 cm. and the current density was 0·035 amp. per sq. cm. During the first hour of the electrolysis the deposit remained bright; after this it became matt, but by adding a further 1 c.c. of the 1% gelatin solution every hour, it was possible to maintain the brilliancy of the surface of the deposited copper. The polished surface, etched with nitric acid and examined under high magnification (×400), showed a high degree of homogeneity distinct from the crystalline character of ordinary electrolytic copper. A section perpendicular to the surface showed alternate layers of copper and gelatin deposited in a regular manner, indicating two alternate stages in the deposition process. The thickness of each layer was about 0·0056 mm. and the time required for the completion of each double layer would average 8·2 mins. The first stage in the deposition process probably consists in the formation of a film of a disperse copper-gelatin phase in which the gelatin, acting as a dispersion medium, retains the discharged copper for some time in the disperse phase. The second stage consists in the precipitation of the copper in a coarser form with consequent formation of a copper and a gelatin layer. The process is then repeated. The hypothesis receives support from measurements which were made of the cathode potential, which showed a periodic variation corresponding roughly with the time, calculated from the microscopical examination of the section, required for the completion of the two stages.—E. H. R.

Copper; Metallographic investigation of electrolytically deposited bright ——. G. Grube. Z. Elektrochem., 1921, 27, 53—54.

An acknowledgment and short discussion of the work of Sieverts and Wippelmann (J., 1916, 604). The different results obtained by these workers from the results recorded in the previous abstract, were probably due to the much stronger gelatin solutions used by Grube and Reusz. Instead of parallel layers of gelatin and copper, Sieverts and Wippelmann observed a fine network structure in sections perpendicular to the plane of deposition.

—E. H. R.

Electrolytic zinc plant of the Anaconda Copper Mining Co., at Great Falls, Mont. F. Laist, F. F. Frick, J. O. Elton, and R. B. Caples. Chem. and Met. Eng., 1921, 24, 245—250.

A detailed description is given of the plant and process used in the recovery of zinc by electrolysis from the complex zinc ores of Butte, containing about 33% Zn and 20% Fe. The ore is roasted in mechanically rabbled multiple-hearth furnaces of the Wedge type at temperatures not exceeding 600°—625° C., in order to produce the maximum amount of zinc sulphate. The flue dust is collected in a Cottrell plant and returned hot to the first hearth, as it has been found that the sulphur trioxide it contains increases the yield of zinc sulphate in the calcine. The roasted ore is leached in two stages; in the first, the whole charge is treated with about half the necessary sulphuric acid partly in the form of spent electrolyte containing 11·5% H_2SO_4 and 7·5% Zn, and partly in the form of a slightly acid liquor obtained from the second stage of the leach, which is carried out with fresh acid, the resulting filtered solution being partly purified before adding to the fresh charge of calcine. The neutral solution obtained in the first stage, containing about 75% of the total soluble zinc, is treated with a small quantity of limestone and ⅛ of the total weight of calcine, whereby part of the copper and all the gelatinous silica and ferric iron are precipitated and carry down the arsenic and antimony. The clarified solution is treated successively with zinc sludge and zinc dust to remove in two stages the copper and cadmium, which are subsequently recovered from the slimes. The purified zinc sulphate solution is electrolysed in lead-lined wooden tanks containing 27 rolled sheet aluminium cathodes and 28 pure lead anodes, the distance between successive cathodes being 4 in. and between anode and cathode 1¾ in. The best deposits are obtained with a current density of 22—25 amps. per sq. ft. and by the addition every 2 hrs. of 1—1·5 oz. of glue per ton of metal deposited. The cathodes are removed when 40 lb. of metal has been deposited, stripped, and the zinc melted under ammonium chloride. The residue from the leaching of the roasted ore is smelted in reverberatories to produce a leady matte containing most of the copper, gold, and silver, a fume containing the greater part of the lead, and a slag with about 11% Zn, which can be worked up later.—A. R. P.

Zinc; Metallurgy of ——. Lemarchands. Rev. Mét., 1920, 17, 803—841.

In continuation of previous work (J., 1920, 338 A) the author has investigated the reactions between zinc oxide and carbon, zinc oxide and carbon monoxide, and zinc and carbon monoxide and finds that zinc oxide is reduced both by carbon and carbon monoxide, the former reaction starting at about 600° C. depending on the rate of heating, and the latter between 350° and 400° C., while the reverse reaction between carbon monoxide and zinc takes places at very high temperatures and is even then very incomplete. The results obtained are discussed from the point of view of the phase rule and the earlier work on the subject is reviewed and criticised.—A. R. P.

Aluminium alloys; Heat treatment of ——. W. Fraenkel and R. Seng. Z. Metallkunde, 1920, 12, 225—237. Chem. Zentr., 1920, 92, II., 115—116.

The authors have studied the heat treatment of aluminium alloys containing 1·5% Cu, 3% Cu, 4% and 8% Zn respectively, together with the effect of additions of 0·1% and 0·5% Mg. For the determination of the lowest temperature to which the alloy must be heated before quenching for improvement in the mechanical properties to take place and the highest temperature at which the effects of heat treatment will persist, the test pieces were subjected to the impact test, as the Brinell hardness number did not give satisfactory results. Alloys free from magnesium showed no noticeable improvement on heat treatment; the copper alloys required a higher temperature than those containing zinc and the resulting metal could be heated to a higher temperature than the zinc alloys without deterioration. The temperature required rises with the content of alloying metal, while the temperature at which the effects disappear depends to a considerable extent on the rate at which the metal has been heated and the time that has elapsed since the heat treatment. The density and specific heat of the metal are not altered appreciably by heat treatment, but the electrical resistance rises immediately the lowest temperature is reached at which improvement takes place, and as the temperature increases further the rate of increase of resistance falls off until eventually a constant value is attained. When the temperature rises to such a point that the effects disappear, the resistance of the alloy reverts to its original value. These facts are consistent with a reaction in a homogeneous system during heat treatment. The authors attribute the effects of heat treatment to the formation from the homogeneous mixed crystal phase of a chemical compound which is soluble in the mixed crystals. The alloy after heat treatment is in the metastable condition.—A. R. P.

Copper-aluminium alloy; Mechanism of solidification of a ——. J. D. Edwards. Chem. and Met. Eng., 1921, 24, 217—220.

The densities of various copper-aluminium alloys containing up to 60% Cu were determined at 20° C. for the solid metal and at temperatures between the melting point and 1000° C. for the liquid metal. On plotting the values found at 20° C. and also their reciprocals (*i.e.*, the specific volumes of the alloys) against the copper content of the series, it was found that the latter curve was a straight line and hence the specific volume and, therefore, the density of any copper-aluminium alloy containing 0—60% Cu could be calculated for any temperature up to its melting point from the known densities and coefficients of expansion of the constituent metals. The mechanism of solidification of No. 12 alloy (commercial aluminium with 8% Cu) was studied by calculating and plotting the densities of the solid and liquid phases in equilibrium during the process of solidification of the alloy and by the construction of an inverse rate cooling curve. The alloy commences to freeze at 636° C. and is completely solid at 540° C., while at 577° C. there is a point of inflexion in the cooling curve due to the separation of the aluminium-silicon eutectic. The density of the first crystals formed (at 636° C.) is greater than that of the liquid from which they separate; they therefore tend to sink, but at 630° C. the densities become equal and at lower temperatures the crystals float in the liquid. The phenomena are discussed in relation to the cooling of an ingot of the alloy.—A. R. P.

Gold-copper alloys; Anomaly in the expansion of ——. A. Portevin and J. Durand. Comptes rend., 1921, 172, 325—327.

The very great brittleness of copper-gold alloys containing 20% or more of copper disappears on tempering owing to a transformation. This transformation is accompanied, on heating, by a sudden expansion. With an alloy containing 25·2% of copper this anomaly occurs at 400° C. during heating and at 350° C. on cooling. The anomaly becomes less important when the alloy has been previously heated to a temperature equal to or exceeding that at which the transformation during heating occurs.—W. G.

Molybdenum; Determination of ——. J. P. Bonardi and E. P. Barrett. U.S. Bureau of Mines, Techn. Paper 230, 1920. 33 pp.

THE following procedures are recommended for the determination of molybdenum in ores, especially in low-grade ores and tailings from the flotation process. *Volumetric method.*—0·5—5·0 g. of ore, containing not more than 0·08 g. Mo, is dissolved in *aqua regia* and the solution evaporated with 20 c.c. of sulphuric acid (1:1). After dilution, the solution is neutralised with ammonia, treated with 10 c.c. excess, boiled, and filtered. The precipitate is washed with hot water, re-dissolved in sulphuric acid, and re-precipitated as before. The combined filtrates are neutralised with sulphuric acid, 12·5 c.c. added in excess, the solution heated to 70° C. and passed through a Jones reductor 20—30 in. long, filled with amalgamated zinc. The reduced solution, which contains the molybdenum as sesquioxide, and should be of a bright green colour, is received in 50 c.c. of a solution containing 50 g. of ferric ammonium sulphate, 45 g. of manganese sulphate, 87·5 c.c. of syrupy phosphoric acid, and 87·5 c.c. of strong sulphuric acid per litre, and the resulting colourless solution titrated with $N/20$ permanganate (1 c.c.=0·0016 g. Mo). The ore may also be decomposed by fusion with six times its weight of sodium peroxide in an iron crucible, in which case the solution of the melt in water is made up to 500 c.c., 250 c.c. filtered through a dry paper, neutralised with sulphuric acid, 12·5 c.c. excess added, and the solution boiled, reduced, and titrated as before. If the ore contains copper, arsenic, or antimony the acid solution before being passed through the reductor is treated with a few c.c. of copper sulphate solution and several grms. of zinc, when part of the arsenic and antimony is evolved with the hydrogen and the remainder precipitated with the copper. The filtered solution is reduced as before. When tungsten or vanadium is present, as is usually the case with wulfenite ores, the molybdenum is precipitated by hydrogen sulphide under pressure from the solution after just acidifying with sulphuric acid and adding 2 g. of tartaric acid. The sulphide is dissolved in *aqua regia* and the solution evaporated with sulphuric acid as before. *Gravimetric method.*—The ore is dissolved in *aqua regia* as described above and the nitric acid eliminated by evaporation with hydrochloric acid, or with 10 c.c. of sulphuric acid if lead is present. The diluted solution is filtered and the filtrate boiled with an excess of ammonia, the precipitate being re-dissolved and re-precipitated with ammonia. Before filtering the solution it is treated with magnesia mixture if phosphorus is present. The combined filtrates are acidified with hydrochloric acid, 5 c.c. excess added, followed by 5—10 g. of sodium acetate, and the liquid titrated hot with lead acetate solution (18 g. per litre) until a test shows no colour with tannic acid. 2 c.c. excess of lead acetate is added and the liquid allowed to stand hot for 15—20 mins., then filtered, and the precipitate washed with 2% ammonium acetate or nitrate solution, dried, ignited together with the paper, and weighed as $PbMoO_4$. In this method lime and sulphur do not interfere, tungsten and vanadium are removed as in the volumetric method, arsenic is removed with magnesia mixture, and copper remains in the filtrate from the lead molybdate.

Formation of carbon at contact substances. Kohlschütter and Nägeli. *See* VII.

PATENTS.

Magnetic alloy sheets; Method of controlling grain growth in ——. V. B. Browne. U.S.P. 1,367,015, 1.2.21. Appl., 6.6.19.

SILICON steel ingots are gradually heated to about 1200° F. (650° C.), then raised to forging temperature, rolled into sheet form, and finally annealed. During rolling the necessary heating between passes is carried out in an oxidising atmosphere and the pressure exerted upon the sheets in the final pass or passes is controlled in accordance with the temperature, whereby a predetermined grain size is produced in the finished sheets after annealing.
—J. W. D.

Alloy steels; Process of producing ——. C. M. Johnson. U.S.P. 1,366,662, 25.1.21. Appl., 12.12.19.

IN smelting iron oxide both ferrosilicon and ferrochromium are introduced into the charge of the smelting furnace.—J. W. D.

Electrodes, welding rods, and soldering sticks. E. H. Jones, and Alloy Welding Processes, Ltd. E.P. 157,534, 14.10.19.

MINERAL graphite, retort graphite, manufactured graphite, or a mixture thereof is incorporated with other alloying materials in electrodes, welding rods, and soldering sticks used for soldering etc. by the electric arc or blowpipe, more particularly such as are required to provide a certain amount of carbon in the deposited metal. The quantity of graphite employed varies from 3% for nickel steel to 4% for cast iron.—J. S. G. T.

Vanadium; Method of recovering —— *from its ores.* P. A. Mackay. E.P. 157,555, 18.10.19.

ONE part of the vanadium ore, *e.g.*, lead vanadate, crushed to 200-mesh, is added gradually with constant stirring to 1·5 parts of fuming sulphuric acid. When the vigorous exothermic reaction has subsided a reducing agent, *e.g.*, sulphur dioxide or hydrochloric acid, is added to the mass to convert the vanadium into vanadyl sulphate. This may also be brought about by addition of a carbonaceous material to the mixture during the reaction. The mass is treated with water, the insoluble lead sulphate and gangue are removed by filtration, and the vanadium is recovered from the solution by electrolysis, or by precipitation with alkalis.—A. R. P.

Furnaces; Heat treatment —— *[for metals].* W. A. Russell, and The Manchester Furnaces, Ltd. E.P. 157,696, 25.8.20.

Two fires at opposite sides of the furnace are supplied with only a limited quantity of air through the fire-bars, and additional secondary air is admitted to the products of combustion while they are in side passages leading from the fire-boxes to the working chamber; the secondary air is preheated by passing it through passages in the walls adjacent to the fire-boxes, and the waste gases are exhausted through ports in the back and mouth of the working chamber.—B. M. V.

Roasting furnace for pyrites, spent oxide, or the like; Rotary ——. Rocholl. G.P. 326,441, 22.10.18.

THE interior of the furnace is divided into a number of cells parallel to the long axis, and a central conveyor charges them through a series of radial channels near the front end of the cells, whilst the gases pass out through openings in front of the channels into a chamber surrounding the conveyor, whence they pass to the scrubbers etc. This method of construction allows the gases to be collected continuously during the charging of the furnace.—A. R. P.

Roasting and sintering; Apparatus for ——. Fellner und Ziegler. G.P. 327,007, 7.8.19.

THE material passes down a vertical shaft furnace, and at the bottom is fed through an automatically adjusted opening into a horizontal rotating tube furnace. The hot gases leaving the latter furnace,

in which the material is sintered, pass up the shaft furnace and dry and preheat the material therein. —L. A. C.

Coating iron, steel, and certain other metals with aluminium; Process for ——. J. Thompson, Ltd., W. J. Thompson, and H. E. Partridge. E.P. 158,010, 25.7.19.

THE surfaces to be coated are first rubbed with pure linseed oil or other suitable oil, then heated to burn off the oil, after which one or more coatings of oil are applied while warm, and, finally, aluminium, or powdered aluminium and a flux, or a paste of oil, powdered aluminium, and a flux is dusted or sprayed on and the metallic articles heated to a suitable temperature to melt the aluminium and flux and burn off the oil. The process is repeated until the necessary thickness of aluminium is obtained, or sheet aluminium of desired thickness may be sweated on to the aluminium coating.—J. W. D.

Sherardising drums. S. O. Cowper-Coles. E.P. 158,154, 20.2.20.

A SHERARDISING drum is provided with a central longitudinal heating tube or with two or more similar tubes disposed eccentrically about the axis. By this means the hot gases for heating the apparatus may be passed through the tube or tubes and over the whole of the outside surface of the drum, or *vice-versâ*, thus ensuring rapid and even heating of the contents. The apparatus is mounted on rollers to allow of rotation, and rests on a carriage running on rails so that it may be moved into and out of the furnace.—A. R. P.

Alloys; Method of preparing metallic —— *and of refining metals and alloys.* H. C. Hall, and Rolls-Royce, Ltd. E.P. 158,156, 25.2.20.

ALLOYING metal or metals, before being introduced into the molten main constituent, are granulated and coated with oil either by melting them and pouring into a suitable oil or by pouring them on to or over a roller or series of rollers immersed in the oil.—J. W. D.

Slag; Process of and apparatus for making ——. J. Lund. U.S.P. 1,366,398, 25.1.21. Appl., 13.4.18.

MOLTEN slag is purified by charging it into a furnace and heating from below, whilst an oxidising gas is applied to the upper surface.—A. B. S.

Flotation cell and method; Pneumatic ——. *Flotation separatory process and apparatus.* J. M. Callow, Assr. to Pneumatic Process Flotation Co. U.S.P. (A) 1,366,766 and (B) 1,366,767, 25.1.21. Appl., (A) 26.4.15, and (B) 27.4.14.

(A) IN order to prevent the formation of a bed of impermeable pulp at the bottom of the separator cell in the pneumatic flotation process, the cell is divided into compartments by means of parallel walls reaching nearly to the bottom and, at these points of restricted communication between the compartments, eddy currents are produced so as to prevent the settling of any material. (B) An apparatus for separating the metalliferous constituents of an ore from the gangue consists of a pulp receptacle provided with means for forming uniformly distributed bubbles within the pulp and for exhausting them from the surface.—A. R. P.

Suspensions [of ores and the like]; Method for working up ——. A. Nathansohn. G.P. 325,706, 23.12.19. Addn. to 323,836 (J., 1921, 120 A).

SUSPENSIONS of ores containing substances sensitive to light, such as uranium minerals or chrome iron ore, are subjected without preliminary treatment to the action of light until the electrical charge on the particles is modified. Addition of substances sensitive to light, as specified in the principal patent, is, in these cases, unnecessary.—A. R. P.

Lead; Process for recovering —— *from ores etc.* S. Huldt. G.P. 325,897, 9.2.18. Conv., 10.3.17.

THE charge is heated electrically to a temperature sufficient to melt it and the slag produced in the reaction. The greater part of the lead settles out on, and may be tapped from, the hearth, while that vaporised is recovered as metal in a condenser from which air is excluded.—A. R. P.

Lead; Process for the removal of —— *from mixtures of metallic vapours. Process and apparatus for separating the vapours of metals or metallic compounds of greatly differing specific gravities, e.g., lead and zinc.* K. Recke. G.P. (A) 325,971, 21.10.17, and (B) 325,972, 23.10.17.

(A) METALLIC vapours containing lead are passed over precipitating agents which are decomposed by heat, *e.g.*, sulphates, carbonates, oxides, or carbides or a mixture of these. The lead in the gases thereby combines with the volatile part of the precipitating agent, *e.g.*, sulphur trioxide from sulphate, and the resulting lead compound is subsequently precipitated, leaving the vapours substantially free from lead. (B) The stream of vapours passing through a horizontal flue impinges on a vertical wall with an extension at the upper end sloping upwards, the height of the wall depending on the relative proportions of the two vapours present. The heavier vapour is, by this means, directed out of the flue into a separate condensing chamber while the lighter vapour flows over the top of the wall to its own condensing chamber. The sloping extension gives the heavier vapour an opportunity to condense or flow back along a longer distance, so that it is almost completely removed from the mixture.—A. R. P.

Aluminium; Process for rendering —— *passive.* O. Pieschel. G.P. 325,943, 3.1.17.

ALUMINIUM, especially that to be used in accumulators, may be rendered passive to sulphuric acid by treatment with ammonia, followed by heating. —A. R. P.

Aluminium; Process and apparatus for the purification of —— *containing less than 1% of impurities.* Physik.-Tech. Reichanstalt. G.P. 326,160, 23.1.19.

THE metal is slowly heated to its melting point and the more easily fusible alloy containing the impurities is pressed out from the mass of pure aluminium crystals. The operation is carried out in an electrically heated cylindrical tube provided with a glass or earthenware funnel at the lower end standing on a small receptacle of similar material to collect the impurities. A fireclay rod closely fitting into the top of the cylinder acts as a pestle with which to press together the purified crystals. Aluminium containing 0·18% Fe and 0·22% Si can be purified by several repetitions of the process so that the final product contains 99·95% Al. (*Cf.* Mylius and Mylius, J., 1921, 150 A.)—A. R. P.

Bauxite; Process of smelting —— *for production of ferro-aluminium in an electric furnace.* Rheinische Elektrowerke A.-G. G.P. 327,055, 16.11.18. Addn. to 308,542 (J., 1920, 754 A).

THE alumina in the slag is removed, with consequent increase in value of the slag as a substitute for carbide, by addition of iron or iron compounds and, if necessary, of coal to the slag, with subsequent separation of the metallic aluminium produced thereby.—L. A. C.

Metals of high melting point, e.g., tungsten; Process for melting ——. J. R. Gault. G.P. 326,424, 21.3.18.

The metal is melted in a crucible constructed of the same metal and supported in a graphite crucible lined with an oxide of the metal. An opening in the bottom of the graphite crucible is closed by a piece of the metal under treatment which melts when the contents of the crucible are completely fused and allows the contents to flow out.
—L. A. C.

Blast-furnace gas; Process for the dry purification of ——. E. Raffloer. G.P. 326,485, 3.4.17.

The gases are passed, first through a thin layer of a valuable filtering medium, *e.g.*, fine ore, coke or coal breeze, in order to precipitate the heavier particles of metallic dust, then through a thicker layer of a less valuable filtering medium, *e.g.*, ground slag, to precipitate the lighter and finer non-metallic particles. The former medium is changed more frequently than the latter and, before use, is mixed with a binding material, preferably of such a nature as to remove the harmful acids and moisture from the gases. Lime is most suitable for this, as it assists in the subsequent briquetting of the material for the recovery of the values therein.
—A. R. P.

Metallic hydrosols; Production of electro-colloidal ——. Chem. Fabr. von Heyden A.-G. G.P. 326,655, 16.2.19.

Hydrosols of metals which are oxidised by electrical disintegration under water are made by carrying out the process in the presence of a reducing agent, *e.g.*, sodium hydrosulphite, catechol, pyrogallol, hydroxylamine, or hydrazine, and of a protective colloid. The reducing agent may be removed from the solution by dialysis or by precipitating the metallic colloid, washing, and re-dissolving it in the absence of air, as the purified colloid is readily oxidisable.—A. R. P.

Agglomerates; Production of ——, *for the blast furnace, from fine ore, flue-dust, burnt pyrites, and fuel.* C. Giesecke. G.P. 327,248, 21.12.17.

Flue-dust, burnt pyrites, and finely divided ore and fuel are mixed with sufficient water and pressed into briquettes which are sintered in a shaft furnace, without drying. By firing the briquettes wet they do not break before sintering.—A. R. P.

Steel; Stable surface alloy ——. P. A. E. Armstrong. E.P. 143,829, 17.7.19. Conv., 24.5.19.

See U.S.P. 1,322,511 of 1919; J., 1920, 117 A.

Electrode for use in depositing molten metal [for welding], and process of making same. W. H. Boorne. E.P. 157,509, 30.9.19.

Double magnesium salt. G.P. 328,413. *See* VII.

XI.—ELECTRO-CHEMISTRY.

Electric furnaces; Operating details of ——. E. T. Moore. Chem. and Met. Eng., 1921, **24**, 171—176.

The paper is based upon a questionnaire submitted to steel manufacturers operating electric furnaces in the United States. When the transformer primary voltage employed exceeds 22,000 volts, the electric furnace service is expensive to instal and operate. All surges should be kept within the closest limits possible. Systems of installation wherein the transformers are located directly behind the furnace, and tilting occurs away from the transformers, require somewhat longer flexible leads than the system of installation in which the furnace tilts at right angles to the line from the transformer to the furnace. In the former system, however, there are no side strains on the electrode masts. Furnace conductors should be installed so as to avoid unnecessary eddy currents. With furnaces of up to one or two tons capacity little is gained by installing double voltage control. In larger furnaces, a high voltage should be used during part of the melting period, and a lower voltage during the refining period. The cost of electrodes amounts to about .9% of the total operating expense of a furnace, and that due to breakage of carbon electrodes amounts to a further 7·7% on the average. The average consumption of carbon electrodes amounts to 39·9 lb. per ton of metal produced. A specification of the lengths, tolerances, diameters, ends, threading, and resistivity of amorphous carbon and graphite electrodes is detailed. The average specific resistance per inch cube at 20° C. of carbon electrodes is not to exceed 0·002 ohm, and for no single electrode is it to exceed 0·0025 ohm. The average specific resistance of graphite electrodes is to be 0·00036 ohm per inch cube. A new type of water-jacketed ring for cooling the electrodes and the port-holes of the furnace roof is described. Amorphous carbon electrodes in which a hard bonding material is used have recently been made. Silica bricks are those chiefly used in electric furnace construction. Magnesite bricks are being increasingly used for the construction of parts of the furnace in contact with the charge and for parts exposed to extremely high temperatures. Dolomite has been successfully employed for the construction of furnace bottoms. The use of the electric furnace in the brass industry is rapidly increasing. The power consumption varies from 174 k.w. hrs. per ton of metal in the case of continuous operation of induction furnaces to 240—500 k.w. hrs. per ton for intermittent operation of arc and resistance types.—J. S. G. T.

Silent electric discharge; Use of the —— *for the detection of fire-damp and for gas analysis.* G. Erlwein and H. Becker. Wiss. Veröffentl. Siemens Konzern, 1920, **1**, 71—75. Chem. Zentr., 1921, **92**, II., 210.

Variations of current strength occur when methane is present in the air flowing through a Siemens ozone tube in which a constant potential difference is maintained. Such variations of current strength are obtained with gaseous mixtures in which chemical action can take place between the constituents. The presence of hydrogen or methane in air causes a considerable increase of current strength. The variations of current strength can be detected by means of a galvanometer of the thermo-electric type. By employing an intensifier tube in conjunction with a relay, signals can be operated indicating the presence of certain gases. The variations of current strength may also be used to determine the concentration of the gas admixed with the air.
—J. S. G. T.

Point electrical discharge in nitrogen. [Determination of minute quantities of impurities.] M. Pirani and E. Lax. Wiss. Veröffentl. Siemens Konzern, 1920, **1**, 167—178. Chem. Zentr., 1921, **92**, I., 200—202.

The determination of the degree of purity of inactive gases such as nitrogen and the rare gases presents great difficulties. An experimental method for the determination of minute quantities of impurities, *e.g.*, a few thousandths per cent., is based upon the work of Franck and Hertz (Phys. Zeits., 1916, **17**, 409) on the ionisation arising from the collisions of molecules and electrons. The current strength of the discharge in a gas is considerably increased when very small quantities of impuri-

ties of an electro-negative character, such as oxygen, nitric oxide, or water, are present. The changes with time of the character of the discharge in nitrogen between a molybdenum point and an aluminium plate, when oxygen and water vapour, respectively, were present as impurities, are described. The pressure of the gas in the discharge vessel was 700 mm. The method enables contamination with oxygen to the extent of 5×10^{-5}% to be determined. The procedure is complicated in the case of contamination with water vapour, owing to dissociation occurring. With slight modification, the method is applicable to the rare gases. Contamination of nitrogen with from 0·1% of hydrogen and upwards can be accurately determined.
—J. S. G. T.

Patents.

Carbon for electrodes; Apparatus for and method of calcining ——. W. Hoopes, Assr. to Aluminium Co. of America. U.S.P. 1,366,457 and 1,366,458, 25.1.21. Appl., 20.5.19.

Coke is calcined in a closed chamber, the raw coke being supplied at the top and calcined coke withdrawn at the bottom. An electric current is passed through an intermediate section of the column of coke to heat it, and a stream of inert gas is forced upwards through the whole column, whereby the calcined coke in the lower section is cooled, the heat uniformly distributed in the intermediate section, and coke in the upper section uniformly preheated. The gas leaving the upper end of the chamber is passed through cleaning and cooling apparatus before being introduced again at the bottom of the chamber.—J. S. G. T.

Cadmium [terminal] leads for zinc electrodes of galvanic cells. Deutsche Gasglühlicht A.-G. (Auerges.). G.P. 328,639, 15.7.19.

By employing cadmium terminal leads in conjunction with zinc electrodes in galvanic cells, practically no solution of zinc occurs on open circuit.
—J. S. G. T.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine oil; New methods for the examination of ——. H. Salvaterra. Chem.-Zeit., 1921, 45, 133—135, 150—151, 158—159.

The method of Tausz (J., 1918, 554 A), depending on the determination of the acid liberated by the action of mercuric chloride on turpentine in methyl alcohol solution, yields untrustworthy results in that the acid liberated varies with the time of reaction and the origin of the turpentine. A further method of Tausz (*loc. cit.*) in which 20 c.c. of turpentine is shaken with an aqueous solution of 70 g. of mercuric acetate in the presence of a little methyl alcohol, followed by heating for 3 hrs. on the water-bath under a reflux condenser and subsequent steam-distillation, the steam-distilled adulterant being measured in a burette, gave results on turpentine adulterated with solvent naphtha, petroleum benzine, and tetralin agreeing to 1%. The method failed, however, when wood turpentine was present, this product giving a distillate of 10—15%. The determination is most conveniently carried out by a modification of Henderson and Agnew's method (Chem. Soc. Trans., 1901, 95, 291) employing yellow mercuric oxide in acetic acid in place of mercurous acetate. The method of oxidation with a mercuric salt, and weighing the reduced mercurous salt as mercurous chloride (Tausz, *loc. cit.*), is untrustworthy, the results varying with the origin of the turpentine, as also are the methods of Nicolardot and Clement (J., 1910, 501) and Krieger (J., 1916, 746). The bromination method of Allina and Salvaterra (J., 1920, 697 A) for the estimation of petroleum benzine in turpentine has been modified to serve also for the estimation of aromatic hydrocarbons as follows:—12 g. of sodium bromate in 10 c.c. of water is placed in a 500 c.c. Claisen flask and 20 c.c. of the oil under examination added.

Hydrobromic acid (sp. gr. 1·38—1·49) is then added from a burette, 1 c.c. at a time, cooling after each addition, and preferably in the absence of daylight, until the bromine colour persists for 5 mins. The cooling is then arrested, the contents of the flask brought to 30° C., allowed to stand at 20°—25° C. for 15 mins., neutralised with solid sodium carbonate, and decolorised with finely-powdered arsenious acid. The Claisen flask side-tube filled with glass wool and beads is then attached and the contents of the flask steam-distilled until three consecutive 5 c.c. portions of aqueous distillate do not contain more than 0·1 c.c. of oil. A total distillate of 60 c.c. is usually sufficient. In the presence of wood turpentine it is advisable to add an excess of 2 c.c. of hydrobromic acid 10 mins. after the completion of the bromination. Wood turpentine is most conveniently detected by the preliminary application of the Halphen colour test, in which a wine- to blood-red coloration appears when bromine vapour is allowed to act on a carbon tetrachloride solution of the oil in presence of phenol. The bromination method gives a maximum error of 1·25%, but fails in the presence of tetralin as an adulterant, about 70% only of this solvent being recoverable in the distillate. The conversion of turpentine into a halogenated addition product non-volatile in steam forms the basis of the following method for the estimation of adulterants:—10 c.c. of the oil is placed in a 1 litre Claisen flask and a solution of 40 g. of iodine and 52 g. of mercuric chloride in 100 c.c. of alcohol added from a burette with constant cooling. The flask is left in the dark for 6 hrs., strong potassium iodide solution is then added to dissolve the mercuric iodide, the solution decolorised with sodium thiosulphate and neutralised with soda. 200 c.c. is then steam-distilled into a half-litre flask, the neck of which is graduated in 0·1 c.c. divisions and which contains 300 c.c. of water. The volume of distilled oil is read off 30 mins. after the end of the distillation. An apparatus correction, obtained by running blank tests on turpentine adulterated with known and increasing amounts of adulterant, is advisable. Comprehensive test analyses with the method showed a maximum error of 0·5%. The difference between the yields from the mercuric acetate method and either of the halogen addition methods when multiplied by the factor 10 gives approximately the proportion of wood turpentine present in the sample.—A. de W.

Resin; New synthetic —— from benzylaniline. W. Herzog. Oesterr. Chem.-Zeit., 1921, 24, 16—17.

A MIXTURE of benzylaniline, 9, formaldehyde (40%), 10, water, 20 g., and concentrated hydrochloric acid, 1 c.c., is heated for 1 hr. under a reflux condenser; the liquid is then decanted from the resinous substance which is formed, the latter washed with hot water and dried at 110° C. About 8·5 g. of transparent, light-coloured resin, resembling colophony, is obtained. The resin is soluble in benzene and in trichloroethylene, the solution being suitable for use as varnish; it is soluble in hot, but not in cold, turpentine.—W. P. S.

Orthodichlorobenzol solvent. Suggestions for its application in the paint and varnish industry and as a constituent of fumigating paints. H. A. Gardner. Paint Manuf. Assoc., U.S.A., Circ. 116, Feb. 21. 7 pp.

THE crude liquid mixture of *p*- and *o*-dichlorobenzene, obtained in the purification of *p*-dichlorobenzene which forms its chief constituent, is miscible with almost all the liquids used in paint and varnish manufacture. In connexion with its use in this direction and independently, it possesses marked insecticidal properties and is of value for combating warehouse insects, clothes moths, cockroaches, and house insects generally.—D. F. T.

Phenolic hexamethylenetetramine compounds. M. Harvey and L. H. Baekeland. J. Ind. Eng. Chem., 1921, 13, 125—131.

THE hexamethylenetetramine addition products of di-*m*-cresol, di-*p*-cresol, mono-*o*-cresol, triphenol, quinol, resorcinol, and carvacrol have been prepared; they are crystalline substances having no definite m.pt. When heated to near their point of liquefaction they are converted into resinous substances of the bakelite type.—W. P. S.

Furfural. Monroe. *See* XX.

PATENTS.

Sulphide composition [pigment] for painting which resists the action of heat and light. Y. Nishizawa. E.P. 156,971, 25.11.19.

NEUTRAL or almost neutral organic compounds containing at least two hydroxyl groups, *e.g.*, esters or salts of tartaric or polyhydroxystearic acid, glycol, saccharides, etc. when mixed with zinc sulphide in the proportion of 1 mol. to 20—40 mols. of the sulphide, render it stable to light and heat. Admixture may be effected by kneading the dry pigment with the hydroxy compound or an aqueous solution of the same, by precipitating the zinc sulphide in presence of the hydroxy compound, or by co-precipitation of the sulphide with an insoluble derivative of the hydroxy compound, *e.g.*, zinc tartrate.—A. de W.

Coke; Drying —— for use as pigment. A. Metzner. G.P. 328,529, 15.8.19.

COKE is quenched with water as it is withdrawn from the retorts, and is charged while still hot into rotating vessels in which it is reduced to a fine dry powder.—L. A. C.

Zinc white; Preventing the harmful effect of —— in mixtures containing colours sensitive to light. A. Eibner. G.P. 328,648, 14.4.15.

ZINC white is boiled with zinc sulphate, zinc chloride, sodium bicarbonate, or phosphoric acid, and the basic compounds formed, which contain at least 12—14% of insoluble sulphate, chloride, carbonate, or phosphate, are dried and may be heated to low incandescence to increase the covering power.—L. A. C.

Phenol-aldehyde condensation products; Solutions of ——. G. H. Howse. E.P. 156,896, 13.10.19.

BENZYL alcohol with or without nitrobenzene, and certain aliphatic and aromatic substances, oils, resins, rubber, waxes, cellulose, pigments, etc., is claimed as a solvent for phenol-aldehyde resins for producing a varnish, *e.g.*, benzyl alcohol 3 pts. and nitrobenzene 25 pts., are used with synthetic resin 80 pts., methylated spirit 32 pts., and methyl ethyl ketone 10 pts., all by weight.—A. de W.

Siccatives; Production of ——. G. Ruth and E. Asser. G.P. 327,374, 18.2.19.

NAPHTHENATES soluble in solvent naphtha and applicable as siccatives are obtained by heating naphthenic acids with oxides or carbonates of chromium or aluminium at 240°—260° C. and expelling any unsaponifiable matter at 350° C., or by precipitation of an alkali naphthenate with an aluminium or chromium salt, washing and drying the precipitate and finally fusing it at 240°—350° C. —D. F. T.

Siccatives and substitutes for linseed oil varnish or oxidised linseed oil; Production of ——. G. Ruth and E. Asser. G.P. 327,375, 21.6.19. Addn. to 327,374 (*cf. supra*).

BY heating aluminium or chromium naphthenate with magnesia, calcium hydroxide, or zinc oxide at 200° C. or at 160° C. under a pressure of 10 atm.,

products are obtained which alone or mixed with other naphthenates, resins, drying oils, or marine animal oils can be used as siccatives, or as a substitute for linseed oil varnish or oxidised linseed oil.—D. F. T.

Cellulose- and spirit-varnishes; Method for softening ——. G. Ruth and E. Asser. G.P. 327,376, 13.6.19.

For softening cellulose- or spirit-varnishes a castor oil substitute consisting of an ester of naphthenic acid with glycol or glycerol is added.—D. F. T.

Chloronaphthalenes; Improvement of the technical mixture of —— used as a substitute for resin. Deutsche Conservierungsges. m.b.H. G.P. 327,704, 6.10.17.

The mixture of chloronaphthalenes is submitted, at 215° C., to the action of a current of air or neutral gas for the removal of the volatile constituents; the residue gives rise to practically no hydrogen chloride, and is not injurious to the health of workers.—D. F. T.

Lead sulphate. E.P. 157,554. *See* VII.

Anti-fouling paints. E.P. 156,827. *See* XIXb.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Hevea latex; Coagulation of ——. G. Vernet. Bull. Caoutchoucs, Inst. Colon. de Marseille, 1919, 107—121.

The author reviews the general theory of latex coagulation and the methods of effecting the separation of rubber from latex by evaporation, centrifuging, and spontaneous coagulation. For the ordinary methods of coagulation the only generally applicable hypothesis is that coagulation depends on the conversion of the albuminoid matter of the latex into an insoluble condition. A suggestion is made that any advantages possessed by the Brazilian wild rubber may be due to the effect, on the freshly prepared coagulum, of special types of micro-organisms peculiar to the district.—D. F. T.

Rubber; Action of certain organic accelerators in the vulcanisation of ——. G. D. Kratz, A. H. Flower, and B. J. Shapiro. J. Ind. Eng. Chem., 1921, 13, 67—70.

The activity of synthetic nitrogenous organic substances (aniline, its homologues and closely related bases) as accelerators is not proportional to the dissociation constants of the original substances, and, with the exception of closely related series, no definite relationship exists between the activities and dissociation constants. Substances which decompose or dissociate into other substances of acid character, or react to form acid substances, do not accelerate unless a neutralising substance is present. Vulcanisation may be effected by heating rubber in a closed vessel with a concentrated aqueous solution of ammonium sulphides (hydrosulphide and polysulphide).—W. P. S.

Patents.

Vulcanisation of rubber, reclaimed rubber and similar mixtures on metals. Felten und Guilleaume, Carlswerk A.-G. G.P. 326,541, 10.10.18.

A layer of adhesive, viscous material, which is not absorbed by rubber, is interposed between the rubber and the metal; the intermediate- and by-products obtained in the manufacture of synthetic rubber are suitable for the purpose.—D. F. T.

Vulcanised products; Production of soft and elastic ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 326,819, 20.2.17.

Vulcanised products of great strength and extensibility are obtained by adding antimony pentoxide to the raw mixture; the result is a red vulcanisate of greater softness, extensibility, elasticity, and toughness than those obtained with "golden antimony" or "Japan red."—D. F. T.

Materials resembling rubber or linoxyn; Manufacture of ——. G. Ruth and E. Asser. G.P. 327,913, 18.2.19.

A feebly alkaline solution of an alkali naphthenate is treated with an aluminium or chromium solution until a salt of hexanaphthenecarboxylic acid (*o*-methylcyclopentanecarboxylic acid) begins to be precipitated; in this way the unpleasant odour of the naphthenates is removed. The naphthenates obtained, when heated to 170° C., yield very viscous solutions resembling solutions of rubber, whilst at 300° C. a horny mass is produced which gives mobile solutions in turpentine, pine oil, and solvent naphtha.—D. F. T.

Rubber; Means [parchmentised or vulcanised paper coverings] to be employed in connexion with the conservation, or storing, of —— in sheet form. J. Y. Johnson. From Diamond State Fibre Co. E.P. 157,673, 30.4.20.

XV.—LEATHER; BONE; HORN; GLUE.

One bath chrome [tanning] liquors and their analysis. W. Klaber. J. Amer. Leather Chem. Assoc., 1919, 14, 622—626.

Commercial chrome tanning liquors may contain aluminium, iron, sodium, chlorides, and organic acids in addition to chromium and SO_4. A portion of the liquor is oxidised with sodium peroxide, boiled, filtered, the Cr_2O_3 (*a*) estimated in the filtrate and Fe_2O_3 (*b*) in the precipitate. The total acidity (*c*) is obtained by titrating the boiling solution with $N/10$ alkali, using phenolphthalein as indicator. A third portion is treated with ammonium chloride and ammonia, filtered, the precipitate washed, dissolved in hydrochloric acid and re-precipitated as before. The precipitate is ignited and weighed as Cr_2O_3, Fe_2O_3, and Al_2O_3 (*d*), and the SO_3 is estimated in the combined filtrates. These operations are repeated with a fourth portion substituting ammonium sulphate for the chloride and sulphuric for hydrochloric acid. The chlorides are estimated in the combined filtrates. The total soda (Na_2O) is obtained by repeating the operations as for the third portion; the combined filtrates are evaporated with excess of nitric acid, ammonium salts decomposed, the residue moistened with sulphuric acid, ignited to constant weight and weighed as sodium sulphate. The "total relative acidity" or ratio of grm.-molecular weights of monobasic acid to grm.-molecular weights of chromic oxide is given by $6c/a$. The amount of SO_3 combined with Na_2O as Na_2SO_4 is deducted from the total SO_3 and the difference is "acid SO_3." The "organic acidity" is the difference between the "total relative acidity" and 152·2 (acid SO_3)/40·03a; $Al_2O_3 = d-(a+b)$. Al_2O_3 and Fe_2O_3 are considered to be present as the normal sulphates and SO_3 calculated to be so combined is subtracted from the "acid SO_3." The difference is SO_3 combined with Cr_2O_3. "Basicity" is replaced by "acidity of Cr_2O_3," given by the formula:—(SO_3 combined with Cr_2O_3/40·03)/(total Cr_2O_3/152·2), which ratio gives the number of (OH) groups of $Cr_2(OH)_6$ replaced by acid radicles.—D. W.

Chrome [tanning] liquor; Effect of concentration of —— on the absorption of its constituents by hide substance. A. W. Thomas and M. W. Kelly. J. Ind. Eng. Chem., 1921, **13**, 65—67.

THE curve showing the results of a 2-day test on the absorption of chromium by hide powder sloped steeply downwards after the concentration of the liquor exceeded approximately 16 g. of chromic oxide per litre in a solution of the composition $Cr(OH)SO_4$, and reached a minimum when the concentration of chromic oxide was 147·5 g. of chromic oxide per litre, this minimum being maintained up to a concentration of 202 g. per litre.
—W. P. S.

Guyacan. G. L. Terrasse and J. F. Anthes. J. Amer. Leather Chem. Assoc., 1919, **14**, 700—701.

GUYACAN (*Cæsalpinia melanocarpa*, Griseb.), of the family *Leguminosæ*, is an undersized tree growing in subtropical Argentina, yielding seed pods locally utilised as tanning agents. Analysis of a ground sample by A.L.C.A. methods showed tans 22·53%, non-tans 37·21%, insolubles 28·86%, water 11·4%, sugars (as glucose) 21·1%. Guyacan resembles dividivi. Its tannin gives a blue-black colour with iron alum, and no precipitate with bromine water. It gives a pale yellow leather which is distinctly plump, soft and pliable.—D. W.

Tanning extracts; Preparation of —— for analysis. R. H. Forbes. J. Amer. Leather Chem. Assoc., 1920, **15**, 21—25.

EXPERIMENTS on the extraction of barks, woods, leaves, etc., show that a percolation method is essential for complete extraction owing to the reabsorption of tanning materials by cellulose, starch, and albuminoids. The percolation method must be modified to suit the material under examination. Continuous extraction at steam heat is suitable for most woody materials, but for canaigre percolation at 50°—55° C. is best. The use of an asbestos filter is necessary to avoid loss of tanning materials. The extractor consists of a Soxhlet fitted with a rubber stopper carrying a 250—500 c.c. funnel filled with water and the stopcock so turned that 500 c.c. of liquid will pass through in 4 hrs. A tank 8"—10" deep has a bottom perforated with holes to receive the rubber stoppers through which the lower ends of the Soxhlet apparatus project. The tank is filled with water at the desired temperature.
—D. W.

Tanning materials; Extraction of —— [for analysis] with different extractors. F. P. Veitch. Bulletin 90, U.S. Dept. Agric. J. Amer. Leather Chem. Assoc., 1920, **15**, 119—122.

A COMPARISON of results obtained by extracting different tanning materials with three kinds of extractors, viz., Soxhlet, Koch, and continuous (Zulkowsky). The continuous form yielded the highest amount of soluble solids. Tannin was highest with the continuous extractor except in the case of sumach, where the Koch apparatus gave the best result.—D. W.

Tannin; Discussion of the methods for the determination of ——. F. P. Veitch. Bull, 90, U.S. Dept. Agric. J. Amer. Leather Chem. Assoc., 1920, **15**, 122—127.

ATTEMPTS to estimate tannin by precipitation with ferric salts, aluminium hydroxide, caustic soda, and gelatin, or by neutralisation with calcium hydroxide gave results inferior to those obtained by the hide powder method. This method yields inaccurate results due to a continuous absorption of solids from the solution by the filter paper during the determination of soluble solids and the absorption of colouring matter and other non-tannin matter by the hide powder.—D. W.

Strap, harness and side leather; Analyses of different tannages of ——. L. M. Whitmore. J. Amer. Leather Chem. Assoc., 1919, **14**, 567—576.

THE results of analyses conducted by the U.S. Bureau of Standards on leathers supplied for Government use during the war are given. The petroleum spirit extract and the mineral acidity most frequently failed to come within the specifications. The Government specifications for harness leathers required 15—20% of grease, but the analyses show that it is impossible to comply with specifications which require a definite amount of grease. The grease content in the samples examined varied from 8·1% to 45·7%. A maximum should be stated for leathers sold by weight, and a minimum for those sold by area. Ash, water-soluble matter, glucose, salts, and acidity maxima can be complied with by tanneries run with chemical control. The degree of tannage varied considerably, and 15° should be allowed between the maximum and minimum.—D. W.

PATENTS.

Phenolsulphonic acids; Preparation of condensation products [tanning agents] from ——. F. Hassler. G.P. 328,340, 9.12.13.

CONDENSATION products with tanning properties are obtained when phenolsulphonic acid or its homologues are heated with the sulphonic acids of aromatic hydrocarbons, particularly the coal tar hydrocarbons of carbolic, creosote, and anthracene oils. The sulphonation product, obtained by the action of concentrated sulphuric acid at 100° C. on Russian petroleum, may also be utilised. The sulphonic acids are heated together for some hours at about 100° C. until no further increase is observable in the precipitate obtained from a small test portion on the addition of gelatin. The reaction may be facilitated by the addition of a condensing agent, such as phosphorus trichloride, thionyl chloride, anhydrous aluminium sulphate, or boric acid. The condensation products are soluble in water, give heavy precipitates with gelatin, and violet colorations with ferric chloride. The condensation products of phenolsulphonic acid with benzenesulphonic acid and with naphthalenesulphonic acid both form viscid or almost solid masses, soluble in water to a clear, almost colourless solution.—G. F. M.

Glue; Manufacture of bone or hide —— which remains liquid in the cold. Luftfahrzeugbau Schütte-Lanz. G.P. 328,692, 9.12.17. Addn. to 325,246 (J., 1920, 827 A).

FORMALDEHYDE and alum are added to the glue solution in addition to formic acid or a formate, as described in the chief patent. The product does not coagulate for several days, and after coagulation is insoluble in water.—L. A. C.

XVI.—SOILS; FERTILISERS.

Soil studies. I. Influence of fertilisers upon the productiveness of several types of soil. II. Influence of fertilisers and plant growth upon soil solubles. W. H. Jordan. New York Agric. Exp. Stat. Bull. 473. Mar., 1920. 27 pages.

THE growth of barley under hot-house conditions on the eleven types of soil examined was influenced very little by the application of either muck or leaf mould. In the first year farmyard manure failed to produce additional growth, but in the second year satisfactory results were obtained. The production with commercial fertilisers was much larger than with stable manure containing the same quantities of nitrogen, phosphorus, and potassium. The increase in yield was not proportional to the increased application of fertilisers.

Slaked lime applied along with stable manure gave very irregular results according to the type of soil. Nitrogen was the only ingredient of the artificial fertilisers which had any marked influence upon the growth of the barley. Under hot-house conditions the soils (one highly productive and one far less productive) appeared to supply sufficient quantities of phosphorus and potassium for luxuriant growth. The application to the soils of soluble compounds of nitrogen, phosphorus, and potassium materially increased the amount of water-soluble substances in the soil. These were utilised by the plants and the reduction in the amount of soluble matter was rapid even before the plants had attained considerable growth. In the later stages the water-soluble material remained practically constant and about equal to that in the soil carrying no crop.—W. G.

Hydrogen-ion concentration of certain three-salt nutrient solutions for plants. A. G. McCall and J. R. Haag. Soil Sci., 1920, **10**, 481—485.

THE hydrogen-ion concentration of the six types of three-salt nutrient solutions described by Livingston and Tottingham (Amer. J. Bot., 1918, **5**, 337—346) have been measured. In general, with any one type, the hydrogen-ion concentration of the solution is a function of the volume-molecular proportion of the dihydrogen phosphate salt present, the sulphates and nitrates apparently playing only a minor part. The types containing KH_2PO_4 have a lower hydrogen-ion concentration than those containing either $Mg(H_2PO_4)_2$ or $Ca(H_2PO_4)_2$. The variations in plant growth, with any one type of solution, could not be correlated with differences in the hydrogen-ion concentrations of the solutions. —W. G.

Carbon bisulphide; Behaviour of —— when injected into the soil and its value as a control for the root-form of the woolly apple aphis. B. R. Leach. Soil Sci., 1920, **10**, 421—451.

THE diffusion of carbon bisulphide in the soil is influenced by the soil type, the soil moisture, and the depth and arrangement of the holes where it is introduced. The soil moisture is the limiting factor. Variations in temperature throughout the growing season apparently do not affect the attainment of maximum diffusion. It was not found possible at any time during the year when soil conditions were favourable to apply carbon bisulphide in an amount sufficient to kill the aphis without causing direct injury to the roots and indirect injury to the branches and foliage of the apple trees.—W. G.

Java indigo plant. Davis. *See* IV.

PATENTS.

Fertiliser dryers. J. P. Hamler, Assee. of P. J. Hamler. E.P. 143,846, 6.5.20. Conv., 28.5.19.

THE apparatus consists essentially of two concentric drums united at their ends only, with a space between them through which steam circulates under pressure. The outer drum has a plain surface; the inner one is of light material and has a corrugated surface; this feature gives increased heating area, allows for contraction and expansion and offers greater resistance to steam pressure, and enables stay-bolts and rivets to be dispensed with. A central shaft passes through the inner drum, and carries arms terminating in blades shaped to conform to the corrugations of the drum; the absence of rivets permits of a very small clearance between the blades and the drum and thereby prevents the formation of a cake, with consequent loss of heat at the surface. The apparatus includes devices for loading and discharging the material; it is also provided with a chamber in communication with the inner drum for drawing off vapours, a diaphragm across the chamber serving to prevent the escape of small particles of dried material. —W. J. W.

Lime for use as fertiliser; Manufacture of ——. R. Mandelbaum. G.P. 328,220, 22.12.18.

LIME or lime marl is either heated in a closed furnace, or is heated in an open furnace and then immediately treated with just sufficient water to convert it into calcium hydroxide, and with carbon dioxide.—L. A. C.

Potassium nitrate etc. G.P. 306,334. *See* VII.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Balance of chlorine during the manufacture of —— and the chlorine content of beetroot. E. Saillard. Comptes rend., 1921, **172**, 283—284.

BEETROOTS contain on the average 0·016% of chlorine, of which 80% passes into the molasses and 19% into the diffusion residues during the manufacture of sugar. In the plant the petioles contain the highest percentage and total amount of chlorine.—W. G.

Carbonatation; Influence of the amount of lime used in —— on the purity and the calcium content of the clarified juice. V. Stanek. Z. Zuckerind. Czechoslov., 1920, **45**, 53—55.

WHEN, owing to the use of frozen or altered roots, the raw juice contains much more than 0·1% of invert sugar, the organic acids that are formed as the result of the action of the lime on the dextrose and lævulose increase to a marked degree the calcium content of the filtered and clarified juice. When such inferior roots are being sliced, the best results in respect of a high quotient of purity and a low calcium content are obtained by using a triple saturation process, the procedure generally being to add 2·3—3·6% of lime to the raw juice, carbonate to an alkalinity corresponding to about 0·10% CaO, filter, add 0·55% more lime, carbonate to 0·05—0·06%, filter, carbonate to 0·001—0·003%, and finally boil.—J. P. O.

Clarification of sugar juice; Increase in the quotient of purity effected by the defecation, sulphitation, and carbonatation processes for the ——. A. Schweizer. Arch. Suikerind. Nederl.-Indië, 1919, **27**, 2013—2016. Int. Sugar J., 1921, **23**, 106—107.

GENERALLY in Java in determining the increase in the quotient due to clarification, the sample of mill juice is allowed to stand for ½ hr. in order to allow the suspended matter to subside, and the entangled air to escape, before observing the Brix reading. J. S. de Haan (Arch. Suikerind. Nederl.-Indië, 1919, **27**, 1897—1906) suggested that more correct results would be obtained if the juice were filtered through paper or else centrifuged in a Sharples machine, but it is pointed out that the clear liquid thus obtained would not correspond to that entering the factory, since the filter paper would adsorb certain of the impurities, and others would be separated by the high-speed centrifuging. A centrifugal machine may, however, be employed for the removal of the suspended matter, provided its speed is not more than 2000 revs. per min.—J. P. O.

Decolorising carbon ("Carboraffin"); Stanek's method of using —— for the purification of liquors in the refinery. V. Skola. Z. Zuckerind. Czechoslov., 1920, **45**, 89—95.

STANEK'S method of passing the liquor to be treated through a layer of decolorising carbon, in the form of a cake in a filter-press (G.P., 317,449; J., 1920, 380 A), is stated to have the following advantages

compared with the usual treatment with animal charcoal:—The amount of water necessary for sweetening off is at least 10 times less, and the loss of sugar 6 times less; the quotient of purity of the wash-waters falls more slowly; and the duration of filtration is much shorter.—J. P. O.

Filtering materials consisting of carbon together with other substances [for use in sugar refining]. Daude. Z. Ver. Deuts. Zuckerind., 1921, 13—32.

THE processes of more than 30 German Patents relating to this subject (from G.P. 307 to G.P. 290,656) are described in order.—J. H. L.

[Sugar and sugar products etc.;] Electric oven for the rapid determination of moisture [in ——]. G. L. Spencer. J. Ind. Eng. Chem., 1921, 13, 70—72.

THE drying capsule is of metal and has its bottom closed with Monel metal filter cloth; the capsule fits tightly into an opening in an annular channel in the oven, this channel being connected with a vacuum pump. A regulated supply of air is admitted to the oven and is heated by means of an electrical resistance in the oven. By the use of this oven, raw sugar may be dried in 10 mins. and cane bagasse in 30 mins.—W. P. S.

Maize cobs. La Forge. *See* XIXA.

PATENT.

Adhesive; Production of an ——. H. Werner. G.P. 327,377, 29.11.17.

SAWDUST is mixed with water and bacteria cultures, and after a pasty consistency is attained, a part of the mixture is subdivided and placed in vessels containing shavings, casein, and a decoction of seaweed. The subdivision is repeated once or twice more, the various fractions being then re-united with the remainder of the original mixture. After thoroughly mixing, the supernatant liquor is separated from the sediment and concentrated or dried.—D. F. T.

XVIII.—FERMENTATION INDUSTRIES.

Saccharase [invertase] preparations; Preparation of highly active ——. O. Svanberg. Z. physiol. Chem., 1921, 112, 104—110. (*Cf.* J., 1920, 636 A, 795 A.)

IT was not found possible to separate invertase from yeast gum by means of filtration through a membrane. This observation coincides with Euler and Fodor's assumption that there is a relationship between the two substances. No improvement in the purity of invertase preparations was observed when they were filtered through a membrane instead of being dialysed.—S. S. Z.

Yeast manufacture by the aeration method; Replacement of malt combs by ammonium salts in ——. A. Wohl and S. Scherdel. Z. angew. Chem., 1921, 34, 41—45.

IN experiments with a 2·5% sugar solution, containing the necessary inorganic salts, and also organic nitrogen in the form of an extract of malt combs, the authors studied the effect of replacing this organic nitrogen, partially or completely, by equivalent amounts of ammonium phosphate. It is concluded that ammonia cannot replace the whole of the organic nitrogenous nutriment without seriously affecting the reproductive and other activities of the yeast; but it may replace a certain proportion (about 50% in the authors' experiments) without impairing either the quality or quantity of the yeast crop, and within such limits ammoniacal nitrogen is a complete substitute for an aqual weight of organic nitrogen. Even when the seed-yeast is poor in nitrogen and therefore contains no reserve which can be drawn upon for reproduction, the yeast will develop well at the expense of mixtures of organic and ammoniacal nitrogen in suitable proportions.—J. H. L.

Alcoholic fermentation; Application of the precipitometer, and of an apparatus for the determination of catalase, to the study of the course of ——. K. Schweizer. Bull. Assoc. Chim. Sucr., 1920, 38, 163—171.

THE simplest and most rapid means of measuring yeast growth in the course of fermentation experiments is to centrifuge a few c.c. of the mixed culture, after addition of sodium carbonate solution, in a tube with a narrow graduated end (precipitometer), for 5 mins. at 2000 revs. per min., and to measure the volume of the deposit. An apparatus devised by Koestler (Jahresb. Molkerei Ruettè, 1909) for the determination of catalase, is recommended by the author for the measurement of the gas evolved during fermentation.—J. H. L.

PATENT.

Glycerin fermentation residues. G.P. 326,728. *See* I.

XIXA.—FOODS.

Milk preservative; Mustard oil as ——. P. Post. Pharm. Weekblad, 1921, 58, 131—138.

ADDITION of mustard oil to milk, in the proportion of 20 drops per litre, retards development of micro-organisms, and samples so treated may be kept unaltered for about four days at normal temperature. The treatment does not affect determinations of specific gravity, fat, acidity, total solids, alcohol test, ash, nitrate, chloride, preservative agents, specific gravity, and refraction of serum, or the polarisation. Mustard oil depresses the freezing-point of milk to an extent dependent on the fat content; the error may be almost entirely eliminated by shaking the milk with 10% of sesame oil. For lactose estimations the filtrate from the asaprol treatment (*cf.* Salomon and Diehl, J., 1919, 301 A) is freed from mustard oil by shaking it three times with petroleum ether; and for albumin estimations the milk must first be mixed with alcohol and the mixture evaporated to half its volume. Catalase cannot be estimated in milk samples which have been treated with mustard oil. —W. J. W.

Milk; Apparatus for determining the catalase content of ——. A. Machens and F. Cordes. Milchw. Zentr., 1921, 50, 25—27.

Two bottles are connected at their shoulders by a short length of glass tube fitted with a three-way tap; one bottle is provided with a tubulure at the bottom which is connected with a vertical graduated tube. Water is placed in this bottle so that the level rises to the zero mark of the graduated tube and 15 c.c. of milk is placed in the other bottle; both are closed with stoppers, the three-way tap is turned to put them in communication with the atmosphere, and the whole apparatus is placed for 15 mins. in an incubator at 37° C. Five c.c. of 1% hydrogen peroxide is then added to the milk, the tap is turned to connect the bottles with each other, and the apparatus kept at 37° C. The increase of pressure due to the liberation of gas from the mixture of milk and hydrogen peroxide is measured by the rise of the water level in the graduated tube.—W. P. S.

Creatine; Simple method of preparation of —— from meat extract. H. Steudel. Z. physiol. Chem., 1921, 112, 53—54.

CREATINE is extracted from meat extract with absolute alcohol on a water-bath and is separated by crystallisation after removing the alcohol by distillation; 1 kg. of extract yields 25—30 g. of air-dry creatine.—S. S. Z.

Proteins; Demonstration of pyrrole substances in ——. N. Troensegaard. Z. physiol. Chem., 1921, 112, 86—103.

THE author advances a theory that the protein molecule is mainly composed of heterocyclic compounds, and in substantiation of this theory experiments are described in which the presence of pyrrole substances in gliadin and gelatin is demonstrated. (*Cf.* J.C.S., Mar.)—S. S. Z.

Proteins; Free amino groups of the ——. S. Edlbacher. Z. physiol Chem., 1921, 112, 80—85. (*Cf.* J., 1920, 796 A; 1921, 126 A.)

CASEIN was methylated with dimethyl sulphate and hydrolysed. The N-methyl value was determined in the various fractions. The results obtained were as follows:—N-methyl value of the monoamino acid fraction 0, of the histidine-arginine fraction 7·5, of the lysine fraction 73·4.—S. S. Z.

Cocoa and its products; Determination of theobromine in ——. R. V. Wadsworth. Analyst, 1921, 46, 32—37.

TEN g. of the sample (previous removal of fat is unnecessary except in the case of cacao beans) is mixed with 3 g. of magnesia and 14 c.c. of water, and the paste is dried partially, but not completely, on a water-bath; after 30 mins. the paste is boiled under a reflux condenser for 30 mins. with 150 c.c. of tetrachloroethane, the solvent, while still hot, decanted through a filter, and the insoluble portion again extracted with tetrachloroethane (120 c.c.). The united extracts are distilled until the volume is reduced to about 5 c.c.; this residual liquid is cooled and 70 c.c. of ether is added. After 18 hrs. the precipitated theobromine is collected, washed with ether, dried at 100° C., and weighed. To the weight is added 0·004 g. to correct for the solubility of the theobromine in the 70 c.c. of ether used. The caffeine present remains in solution in the ether.—W. P. S.

Corn [maize] cobs; Utilisation of ——. F. B. La Forge. Paper, Dec. 22, 1920, 15—18, 32.

BY digesting maize cobs under pressure with water soluble gums and other carbohydrates are obtained which can be used as adhesives or as a source of furfural. The latter is obtained by treatment of the gums with mineral acid (*cf.* Monroe, p. 194 A). The gums can be used as a substitute for dextrin. Another adhesive is obtained from the residues before the extraction of the cellulose, by treating the cellulosic press-cake with a 1% solution of caustic soda. After the elimination of the adhesives the pulp can be handled in the same manner as wood pulp, but the fibre of the maize cob cellulose is very short, and therefore the use of this product is suggested as a substitute for clay as a filler. —J. C. K.

Cattle food consisting of hydrolysed sawdust; Preparation and analysis of ——. E. C. Sherrard and G. W. Blanco. J. Ind. Eng. Chem., 1921, 13, 61—65.

WHITE pine sawdust was digested with 1·8% sulphuric acid for 20 mins. under a steam pressure of about 120 lb. per sq. in., sufficient water being also added to the sawdust to raise the ratio of water to dry wood to about 1·25:1. The acid liquor was removed as far as possible by centrifuging the mass, the latter extracted five times with hot water, the aqueous extracts and the acid liquor mixed, neutralised with calcium carbonate, filtered, and evaporated under reduced pressure to a syrup. This syrup was added to the extracted material which had been dried in an oven, and the whole again dried until the water-content was less than 15%. The product, ground to pass a 100-mesh sieve, yielded the following results on analysis, the figures in brackets being the corresponding values for the untreated sawdust:—Moisture, 3·88 (6·39); water-soluble, 31·11 (9·21); ether-soluble, 3·80 (4·88); soluble in 1% sodium hydroxide solution, 40·23 (25·39); acetic acid, 0·65 (0·91); pentosan, 5·66 (9·86); methylpentosan, 2·50 (2·83); cellulose, 37·90 (54·45); crude fibre, 49·31 (60·81); reducing sugars, 16·20 (none); ash, 3·35 (1·52)%. The cellulose obtained from the digested wood was converted into a viscous semi-transparent mass when treated with 17·5% sodium hydroxide solution, and thus differed from the cellulose from the untreated sawdust, over 50% of this remaining unaffected by the alkali. —W. P. S.

Disinfecting cereals. Piutti and Mango. *See* XIXB.

Inositol phosphoric acids. (1) Posternak. (2) Anderson. *See* XX.

PATENTS.

Lupins; Removal of the bitterness of —— by means of a saline acid solution. C. F. Hildebrandt and B. Rewald. G.P. 327,368, 6.7.18.

THE lupins are steeped in water for several hours; a small quantity of a saline acid solution is then introduced and the soaking continued for several hours longer. The treated material is washed with water and finally extracted with pure water. —D. F. T.

Evaporation of liquids [milk etc.]; Process of and apparatus for heat treatment or ——. J. F. Ruff. E.P. 157,514, 6.10.19.

XIXB.—WATER PURIFICATION; SANITATION.

Cereals; Use of chloropicrin in the disinfection of ——. A. Piutti and A. Mango. Giorn. Chim. Ind. Appl., 1920, 2, 677—682.

CHLOROPICRIN, applied in the proportion of 20 c.c. per cub.m. of space, and allowed to act for at least a week at a temperature not lower than 15° C., serves as an efficient parasiticide. The grain store should be sealed hermetically and should be away from inhabited localities, and workmen engaged in handling the chloropicrin, which is sprinkled directly on to the grain, should be furnished with masks impregnated with a solution of 5 pts. of glycerin, 20 pts. of sodium sulphite, and 5 pts. of sodium carbonate per 100 pts. of water. The grain should be turned 24 hrs. after the store has been opened. No injurious effect is produced on the grain or on the flour made therefrom, and the panification of the flour with yeast remains unaffected. The germination is, however, lowered by about one-third, so that treatment with chloropicrin should not be applied with grain to be used as seed. The treatment is cheaper than that with carbon bisulphide, and, furthermore, all danger of fire is avoided.—T. H. P.

Oligodynamics of silver. R. Doerr. Biochem. Zeits., 1921, 113, 58—69. (*Cf.* J., 1920, 702 A.)

SILVER which has been inactivated by heating to redness regains its bactericidal activity when exposed to the atmosphere. If it is placed in melted paraffin this regeneration does not take place. The oligodynamic action is due to the formation of soluble silver compounds on the surface of the metal through the oxidising influence of the atmosphere. A certain surface of silver imparts a definite oligodynamic action to a volume of water, and this action diminishes owing to the fact that the soluble substances on the surface diffuse; only by the introduction of a fresh piece of silver with a surface covered with the soluble substances can the oligodynamic action be renewed. The metallic silver does not go into solution. Typhoid, paratyphoid A, and paratyphoid B form colonies on agar plates at a certain distance from the silver and behave under the conditions almost like *B. coli.* On the addition of lactose, on the other hand, the difference in the distance from the silver at which the typhoid groups and *B. coli* will form colonies is more marked and the author utilises this phenomenon in order to isolate *B. coli* from such a mixture of organisms. In some instances the author succeeded in suppressing the growth of *B. coli* in the mixture by means of the oligodynamic action of silver in a fluid medium.—S. S. Z.

Toxic gases; Use of alkaline polysulphides for neutralising certain ——. Desgrez, Guillemard, and Labat. Comptes rend., 1921, 172, 342—344.

USING a liquid containing 240 g. of sodium polysulphide and 140 c.c. of soap-boilers' lye per litre, diluted just before use by addition of 10 l. of water, the authors have determined the volume of liquid to be sprayed into 20 cub. m. to neutralise given amounts of different toxic gases. The composition of the spray fluid varies with the type of commercial polysulphide used.—W. G.

Copper; Non-toxicity of —— *for mildew.* G. and G. Villedieu. Comptes rend., 1921, 172, 335—336.

IT is shown that, in a solution of ammonium carbonate (1 in 10,000 or 1 in 8000), saturated with basic copper carbonate, *Phytophthora infestans* grows and the conidiæ evolve zoospores, which in their turn continue to evolve and grow.— W. G.

PATENTS.

Anti-fouling paints; Poison compositions for —— *and for other purposes.* J. A. Lillie. E.P. 156,827, 14.4.19.

THE juice of the West African upa, iza, or ipa shrub (*Alchornea cordifolia*, Muell.-Arg.), especially the juice of the berries or the dried and pounded berries, is used alone or in suitable combination as an anti-fouling paint for ships' bottoms or for other purposes.—A. de W.

Sheep and cattle dips and washes. I. McDougall and F. Howles. E.P. 157,527, 11.10.19.

A NON-IRRITANT sheep dip which is unaffected by the hardness of the water used for solution is prepared by heating 35 pts. of arsenious oxide with 65 pts. or more of glycerin, and dissolving 1 lb. of the product, which is a viscous white fluid, in 10 galls. of water.—L. A. C.

Ultra-violet rays; Apparatus for treating liquids by ——. J. C. Pole, Assr. to The Chemical Foundation, Inc. U.S.P. 1,367,090, 1.2.21. Appl., 28.3.16. Renewed 21.5.20.

A NUMBER of liquid containers are provided with passages of varying cross-section and a narrow channel constructed of a material capable of transmitting ultra-violet rays. An electric lamp adjoining the containers supplies rays both to the containers and to the channel.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Cocaine; Purification of ——. L. Reutter de Rosemont. Bull. Sci. Pharmacol., 1920, 27, 359—363. Chem. Zentr., 1921, 92, I., 90.

FOUR processes for the purification of crude Brazilian or Argentine cocaine from hygrine, isotropinecocaine, isococaine, and cinnamylcocaine were examined. By dissolving the crude material in hot petroleum ether, pouring off the solution after cooling from the oily resinous residue, precipitating the cocaine with dry hydrogen chloride, dissolving the hydrochloride in water, precipitating isococaine etc. by ammonium carbonate, and then adding ammonia, nearly chemically pure cocaine in 73—75% yield is obtained. By dissolving the crude product in amyl alcohol at 50°—60° C., filtering the cold solution, extracting with dilute hydrochloric acid, and then treating further as in the first method, a yield of 73% is obtained. A 70—73% yield of pure cocaine is obtained by dissolving the crude cocaine in dilute hydrochloric acid, shaking out with amyl alcohol in presence of ammonium carbonate, and treating the aqueous layer as in the first method, the cocaine obtained being recrystallised from a mixture of equal parts of alcohol, ether, and ligroin. By dissolving the crude material in hot naphthalenesulphonic acid, acetic acid, benzoic acid, or oxalic acid, preparatory to treatment by the first method, a yield of 76—79% is obtained. The above yields can be increased by working up the resinous residue to ecgonine and synthetic cocaine.—G. F. M.

Theobromine and caffeine; Reaction to distinguish ——. M. Malmy. J. Pharm. Chim., 1921, 23, 89—91.

THE difference between the behaviour of theobromine bismuthic iodide and the corresponding compound of caffeine towards the reducing action of hydriodic acid may be used to differentiate these two substances. The test is conveniently performed as follows:—0·05 g. of theobromine or caffeine is shaken with 10 c.c. of water and 0·5 c.c. of freshly prepared potassium bismuthic iodide solution. In each case an orange-coloured precipitate is formed, and 5 drops of a 10% tincture of iodine (not freshly prepared, so that it may contain a small proportion of hydriodic acid) is added. The colour of the caffeine bismuthic iodide precipitate changes to a bright red, whilst the theobromine precipitate becomes brown in 15 mins., and dark chocolate brown in less than 30 mins. owing to reduction. A dilute solution of hydriodic acid, containing not more than 1% of hydrogen iodide, may be used instead of the tincture of iodine.—G. F. M.

Lycorine; Occurrence of —— *in the family of the Amaryllidaceæ.* K. Gorter. Bull. Jard. Bot., 1920, 2, 331—334. Chem. Zentr., 1921, 92, I., 92.

IN addition to the already known sources of lycorine in the *Amaryllidaceæ*, the alkaloid also occurs to the extent of 0·9% in the fresh tubercles of *Amaryllis Belladonna*, 0·3% in the fresh roots of *Clivia miniata* Benth., 0·9% in *Sprekelia formosissima* Herb., in *Cooperia Drummondii* Herb., and in the fresh tubers of *Cyrtanthus pallidus* Sims. The alkaloids of the first and fourth of the above plants designated by Fragner (J., 1891, 847) belamarin and amaryllin, and the alkaloid resembling veratrine isolated by Molle (Jahresber. Ph., 1903, 27) from *C. miniata* are all identical with lycorine. The solubility of lycorine in chloroform and ether observed by Fragner applies only to the amorphous variety, crystalline lycorine being insoluble.—G. F. M.

Glucosides. VIII. Glycyrrhizin. P. Karrer, W. Karrer, and J. C. Chao. Helv. Chim. Acta, 1921, 4, 100—112.

GLYCYRRHIZIC acid, from *Glycyrrhiza glabra*, is free from nitrogen, the supposed presence of the latter being probably due to the formation, during the combustion, of methane. Glycyrrhetic acid, prepared by hydrolysing potassium glycyrrhizate, has the formula $C_{45}H_{72}O_6$ or possibly $C_{44}H_{70}O_6$. Potassium glycyrrhizate undergoes complicated hydrolysis, the final products being glycyrrhetic acid (1 mol.) and glycuronic acid lactone (2 mols.). (*Cf.* J.C.S., Mar.)—T. H. P.

Hiptagin, a new glucoside from Hiptage madablota, Gaertn. K. Gorter. Bull. Jard. Bot., 1920, 2, 187—202. Chem. Zentr., 1921, 92, I., 91—92.

HIPTAGIN, $C_{10}H_{14}N_2O_9,\frac{1}{2}H_2O$, obtained by extraction of the roots with acetone or ethyl acetate, forms fine silky needles, m.p. 110° C., insoluble in ether, chloroform, hydrocarbons, etc., and not hydrolysed by emulsin. By the action of dilute acids or alkalis dextrose is formed and an intermediate product, hiptagenin, which was not isolated but which gave tartronic acid on further treatment with acids, and ammonia and hydrogen cyanide with alkalis. From these and other considerations it is concluded that hiptagenin is an iso-oxazole derivative, and hiptagin its glucoside ether.
—G. F. M.

Inositol hexaphosphate. S. Posternak. Helv. Chim. Acta, 1921, 4, 150—165.

THE results previously obtained (J., 1919, 695 A) are confirmed, and Anderson's criticisms on the author's work refuted (J., 1920, 673 A). Owing to the energetic retention, by inositol hexaphosphate and most of its salts, of 3 mols. of water which it is impossible to expel, even partially, without decomposing the compounds, the author proposes to express the formula in the form, $C_6H_{18}O_{24}P_6,3H_2O$.
—T. H. P.

Inositol phosphoric acids. I. Synthesis of phytic acid. II. Composition of inositol phosphoric acid of plants. R. J. Anderson. New York Agric. Exp. Stat. Tech. Bull. 79, May, 1920. 22 pages. (*Cf.* J., 1920, 673 A.)

THE author attempted to repeat Posternak's synthesis of phytic acid by heating together inositol, phosphoric acid, and phosphorus pentoxide (J., 1919, 695 A), but the only product which he could isolate corresponded to an inositol ester of pyrophosphoric acid having the formula $C_6H_{12}O_{16}P_4$. Its properties and reactions differ in several important particulars from those of phytic acid. It gives a silver salt $C_6H_8O_{16}P_4Ag_4$ and a barium salt $C_{12}H_{16}O_{32}P_8Ba_3$. Further investigations of the inositol phosphoric acid of wheat bran, including analyses of the carefully purified barium salts, lead to the conclusion that the phytic acid of plants is inositol hexaphosphoric acid, $C_6H_6O_6[PO(OH)_2]_6$.—W. G.

D. M. (Diphenylamine arsenious chloride). A. Contardi. Giorn. Chim. Ind. Appl., 1920, 1, 11—26.

WHEN the double compound of aniline hydrochloride and zinc chloride (1 mol.) is heated with aniline (2 mols.), ammonia is liberated and diphenylamine formed: $ZnCl_2,2C_6H_5.NH_2,HCl+4C_6H_5.NH_2 = 2NH_4Cl+2(C_6H_5)_2NH+ZnCl_2,2C_6H_5.NH_2$ and $ZnCl_2,2C_6H_5.NH_2+2NH_4Cl=ZnCl_2,2C_6H_5.NH_2,HCl+2NH_3$. The preliminary preparation of aniline hydrochloride is unnecessary, addition of zinc and ammonium chlorides to heated aniline yielding diphenylamine; after a small quantity of zinc chloride has been added and the reaction started, a mixture of zinc oxide and ammonium chloride may be introduced. Successive additions of aniline may be made and the residual mass fractionally distilled in a vacuum, a yield of 90% of diphenylamine being obtainable. A plant designed to produce about 500 kg. of diphenylamine per 48 hrs. is described. For the preparation of diphenylamine arsenious chloride, known as D.M. or adamsite, fused diphenylamine (1 mol.) is treated with hydrochloric acid (sp. gr. 1·18) (1·1 mol.), the mass heated and stirred until almost free from water, and the hydrochloride (2 mols.), either moist or after further drying in a desiccator at 50°—60° C., mixed with arsenic trioxide (1 mol.) and fused in a covered vessel provided with a wide efflux tube; when fusion has been maintained for 4 hrs., the temperature rises to 200° C. and the reaction is finished, a 95% yield being obtained. A plant for producing 6 tons of D.M. per 24 hrs. is described.—T. H. P.

Furfural; Preparation and technical uses of ——. K. P. Monroe. J. Ind. Eng. Chem., 1921, 13, 133—135.

FIVE hundred g. of maize cob adhesive (a concentrated aqueous suspension of gums rich in pentosan) is steam distilled with a mixture of 150 c.c. of sulphuric acid (sp. gr. 1·84) and 500 c.c. of water, 4 l. of distillate being collected. The distillate is again distilled through an efficient fractionating column; the furfural distils over in the first portion of the distillate and is separated from the aqueous portion of the distillate and once more distilled. The yield is about 26% of the solid substance contained in the original material. Furfural reacts with alkali sulphides and hydroxides to yield two direct dyes, and gives resinous condensation products with phenols. By the interaction of furfural alone or with acetone in the presence of alkalis soluble resins are obtained which may be useful in the varnish industry. (*Cf.* La Forge, p. 192 A).—W. P. S.

Amines; General method of preparation of —— from aldehydes or ketones. G. Mignonac. Comptes rend., 1921, 172, 223—226.

THE aldehyde or ketone is dissolved in the requisite amount of an 8% solution of ammonia in absolute alcohol, finely divided nickel is added as a catalyst, and the mixture is shaken in hydrogen at the ordinary temperature and pressure until the absorption of hydrogen ceases. The amine is then isolated in the usual manner.—W. G.

Amines; Catalytic preparation of secondary —— and attempts at alkylation of these bases. A. Mailhe. Comptes rend., 1921, 172, 280—283.

SCHIFF's bases of the type RCH:NR′ may readily be converted into the corresponding secondary amines in good yields by suspending in the liquid at 170° C. a little finely divided nickel and passing in a current of hydrogen. When the vapour of a secondary amine is mixed with the vapour of methyl or ethyl alcohol and passed over alumina at 380°—400° C., the corresponding tertiary amine is not obtained, but the molecule is decomposed. Thus benzylphenylamine and methyl alcohol give toluene and methyl- and dimethylaniline.—W. G.

Electrolytic oxidation of methyl and ethyl alcohols in alkaline solution. Electrolytic formation of methane. E. Müller and A. Rius y Miró. Z. Elektrochem., 1921, 27, 54—57.

BY the electrolytic oxidation of methyl alcohol in aqueous caustic soda solution at a platinum anode, small quantities of hydrogen are formed at ordinary temperatures. The most favourable strength of alkali is about 4*N*, and variations in the current density between 0·006 and 0·018 amp. per sq. cm. have little influence. The best yield of hydrogen obtained was about 11·0% of the theoretical. Ethyl alcohol under similar conditions gives a mixture of hydrogen and methane. Attempts to obtain

hydrogen by the electrolysis of formaldehyde or formic acid at platinum anodes failed, so the formation of these as intermediate sources of hydrogen in the oxidation of methyl alcohol is excluded. The hypothesis is put forward that an oxy-alcohol is formed primarily and that this decomposes into hydrogen and formaldehyde. In the case of ethyl alcohol, the oxy-alcohol formed can break down to give hydrogen and methane, or ethane, but only traces of ethane, at most, are formed. (*Cf.* J.C.S., April.)—E. H. R.

Creatine. Steudel. *See* XIXA.

Maize cobs. La Forge. *See* XIXA.

Patents.

Lobelia inflata; Process for obtaining the active ingredient of ——. C. H. Boehringer Sohn. E.P. 145,621, 29.6.20. Conv., 4.4.14.

The plant when extracted with alcohol, ether, or benzene, and the extractive matter purified by transference to dilute acid solution and back to ether, furnishes a crude lobeline which actually contains at least three alkaloids—α-lobeline, $C_{21}H_{23}NO_2$, colourless crystals, m.p. 120° C., having the characteristic physiological action of *Lobelia inflata*; β-lobeline, non-crystalline and characterised by a hydrochloride sparingly soluble in water; and γ-lobeline, also non-crystalline, and forming non-crystalline salts. The α- and β-bases form sparingly soluble mercurous double salts which may serve for the purification of the alkaloids. For the isolation of pure α-lobeline the crude alkaloidal mixture obtained as above is dissolved in dilute hydrochloric acid; on standing, β-lobeline hydrochloride crystallises out, whilst α-lobeline hydrochloride is extracted from the solution by repeated agitation with chloroform. After agitating with soda solution, the chloroform solution is evaporated to dryness; the residue crystallises after keeping a short time, and the base may be purified by recrystallising from ether.—G. F. M.

Butyl p-aminobenzoate; Manufacture of normal ——. Soc. Chim. des Usines du Rhône. E.P. 148,743, 12.5.20. Conv., 30.7.19.

n-Butyl *p*-aminobenzoate, prepared by the esterification of *p*-aminobenzoic acid with *n*-butyl alcohol in presence of gaseous hydrogen chloride, or by esterification of *p*-nitrobenzoyl chloride or *p*-nitrobenzoic acid with *n*-butyl alcohol by the usual methods, and reduction of the resulting *n*-butyl *p*-nitrobenzoate, is a crystalline substance, m.p. 59° C., b.p. 173°—174° C. at 8 mm. pressure. It is only very slightly soluble in water. *n*-Butyl *p*-nitrobenzoate, a substance not hitherto described, crystallises in lamellæ. It melts at 35° C., and boils at 160° C. at 8 mm. pressure.—G. F. M.

Acetic acid; Manufacture of ——. H. Dreyfus. E.P. 156,916, 17.10.19.

Improved results in the oxidation of acetaldehyde to acetic acid are obtained by employing as accelerating catalyst about 0·25% of ferric oxide specially prepared by precipitation from a ferric salt solution and subsequent calcination at a temperature between 310° and 500° C., the catalytic activity reaching its maximum when the oxide has been heated to above 400° C. This catalyst can also be used advantageously in conjunction with sodium acetate in proportion not greater than double that of the ferric oxide. The operation is conducted with liquid acetaldehyde in a closed vessel provided with a high velocity stirrer, and if pure oxygen is employed the gas is absorbed as fast as it is introduced, and the vessel must be cooled to keep the temperature down to about 10° C. With air the absorption is slower.—G. F. M.

Diethyl sulphate; Preparation of ——. N. V. Sidgwick, S. G. Preston, and A. Boake, Roberts and Co., Ltd. E.P. 157,578, 30.10.19.

Diethyl sulphate is obtained by passing ethylene, or ethylene mixed with an inert gas, into sulphuric acid of preferably about 100% strength, or into a solution of ethyl hydrogen sulphate in sulphuric acid, prepared by any other means such as by the action of ethyl alcohol on sulphuric acid. The best results are obtained at a temperature of about 75° C., using ethylene in large excess. The diethyl sulphate is isolated from the reaction mixture by extraction with an immiscible solvent such as benzene or ligroin, or in any other suitable manner, and is purified by distillation under reduced pressure, the yield being at least 30% by weight of the reaction product. If desired the reaction mixture can be used as an ethylating agent without further treatment.—G. F. M.

Saccharin; Process for producing ——. J. Bebie, Assr. to Monsanto Chemical Works. U.S.P. 1,366,349, 25.1.21. Appl., 7.9.20.

o-Toluenesulphamide is oxidised below 75° C. by means of a mixture containing chromic acid dissolved in sulphuric acid of at least 50% strength by weight.—L. A. C.

Apple-oil; Synthetic ——. F. B. Power and V. K. Chesnut. U.S.P. 1,366,541, 25.1.21. Appl., 19.7.20.

The oil consists of the amyl esters of formic, acetic, caproic, and caprylic acids, together with acetaldehyde.—L. A. C.

Urea; Evaporating solutions of —— [*prepared from calcium cyanamide*]. A.-G. für Stickstoffdünger. G.P. 299,132, 19.3.16.

A weak acid or acid salt, *e.g.*, 1% of phosphoric acid or superphosphate, is added to the solution during evaporation to hinder loss of nitrogen and to prevent reaction between the sulphur compounds present in the solution and metal parts of the apparatus and consequent contamination of the urea with metallic sulphides.—L. A. C.

Urea; Manufacture of —— [*from calcium cyanamide*]. A.-G. für Stickstoffdünger. G.P. 301,262, 22.3.16.

A catalyst, such as manganese dioxide, is added to the paste obtained by treating a suspension of calcium cyanamide in water with carbon dioxide. On heating the mixture at 85° C. for ½ hr. the whole of the cyanamide is converted into urea. The catalyst is advantageously prepared *in situ* by adding potassium permanganate to the paste and then a reducing agent such as hydrogen sulphide, thiourea, or sulphur dioxide, or by the action of calcium carbonate on ferric chloride or sulphate. —L. A. C.

Urea; Manufacture of ——. Badische Anilin und Soda Fabr. G.P. 301,751, 30.11.16.

In heating under pressure compounds of ammonia with carbon dioxide for the manufacture of urea, action on the metal parts of the apparatus is prevented by excluding oxygen and/or using excess of ammonia.—L. A. C.

Ointment bases; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 301,665, 27.6.16.

Naphthalene or its derivatives, *e.g.*, methylnaphthalene, is condensed with aralkyl halides, *e.g.*, benzyl or xylyl chloride, by heating in the presence of iron or iron compounds. The oily hydrocarbons produced if mixed with paraffins, spermaceti, or the like, yield soft and stable ointment bases.—L. A. C.

Alcohols; Manufacture of high molecular ——. G. Schicht A.-G. G.P. 327,510, 16.5.16. Conv., 12.4.15.

ALKYL derivatives of higher oxidised compounds than the required alcohols are heated with aqueous alkali hydroxides and alcohols. Stearic acid ketone (2 mols.), aqueous sodium hydroxide (1 mol.), and ethyl alcohol (2 mols.) when heated together for 3—6 hrs. at 200°—300° C. yield acetic acid and 1.8-pentatriacontanol, $C_{35}H_{71}OH$, m.p. 93°—94° C. Alcohols produced from resin acids are viscous liquids. A small part of the product is often hydrolysed to ethers or ethylene compounds. Aldehydes or peroxides produced together with acids and alcohols by the incomplete oxidation with air or oxygen of paraffin hydrocarbons are converted by treatment with aqueous alkalis into the corresponding alcohols; wax alcohols are obtained in this way from pentatriacontane.—L. A. C.

Berberine, cotarnine, and hydrastinine; Preparation of double salts of ——. M. Freund. G.P. 328,101, 14.12.18.

WELL-DEFINED double salts are produced when salts of berberine with polybasic acids are brought into solution with similar salts of cotarnine and/or hydrastinine, and crystallised together, or when the acid is neutralised with a mixture in suitable proportions of berberine with cotarnine and/or hydrastinine. These double salts have a physiological action different from that of the individual constituents. The following salts are described:— Double sulphate containing ½ equiv. each of berberine and cotarnine, yellow needles, m.p. 190° C.; a similar double salt containing hydrastinine instead of cotarnine, m.p. 172°—173° C.; a complex sulphate containing ½ equiv. of berberine, and ¼ equiv. each of hydrastinine and cotarnine, yellow needles soluble in water and alcohol, m.p. 160° C.; and a double salt prepared from phosphoric acid (1 mol.) and 1 mol. each of hydrastinine and berberine, which decomposes at 225° C.—G. F. M.

Hydrocotarnine; Preparation of derivatives of ——. M. Freund. G.P. 328,102, 8.4.19.

BY the action of a mixture of acetic anhydride and sulphuric acid on hydrocotarnine for 30 mins. at 30° C. a hydrocotarninesulphonic acid, $C_{12}H_{15}O_6NS$, is produced. The substance has both acidic and basic properties, is soluble in hot water, insoluble in organic solvents, and melts at 292° C. If the treatment of hydrocotarnine with the acid reagent is carried out at 80°—85° C. a crystalline base, $C_{14}H_{17}O_4N$, m.p. 130° C., is produced. It is soluble in benzene, chloroform, and boiling alcohol, and is an acetylhydrocotarnine (6.7-methylenedioxy-8-methoxy-5-acetyl-2-methyltetrahydroisoquinoline). Both the above compounds possess therapeutic value.—G. F. M.

Ethyl alcohol; [Electrolytic] manufacture of —— from acetaldehyde. Chem. Fabr. Griesheim-Elektron. G.P. 328,342, 28.10.17.

ACETALDEHYDE is passed into an acid solution in the cathode chamber of an electrolytic cell under such conditions that a low concentration, *i.e.*, less than 10%, of acetaldehyde is maintained in the solution.—L. A. C.

Bromvitellin; Preparation of ——. P. Bergell. G.P. 330,256, 2.8.18.

VITELLIN from egg-yolk is treated with bromine in the presence of an indifferent solvent, such as carbon tetrachloride, benzene, etc., and the resulting product dried at a low temperature. It is a bright yellow substance, insoluble in water, organic solvents, or dilute acids, but soluble in dilute alkalis. It contains 10% Br, which is completely removed as sodium bromide on prolonged boiling with sodium hydroxide. It serves as a nutrient and sedative, especially in cases of undernourishment where the nerves are also affected. —B. V. S.

Metallic hydrosols. G.P. 326,655. *See* X.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Electrical conductors; New property of substances which are feeble ——. G. Reboul. Comptes rend., 1921, 172, 210—212.

IN explanation of the phenomena previously recorded (J., 1921, 62 A), it is suggested that at the portions of the paper or other material where discontinuities occur, the potential differences are sufficient to produce disruptive discharges either in the conductor itself or in the surrounding medium. The discharges thus produced are accompanied by the emission of a radiation which is very readily absorbed and which, like ultra-violet rays and X-rays, though invisible to the eye, is capable of acting on a photographic plate.—W. G.

PATENTS.

Dye transfer printing from photographic negatives. W. F. Donisthorpe, and Dye Impression Photos, Ltd. E.P. 158,021, 30.9.19.

IN the process described in E.P. 13,874 of 1907 (J., 1908, 140), by which a negative is selectively hardened by treatment with a solution of a vanadium salt, dyed, and the dye then transferred, by contact, to a prepared paper, the staining of the hardened negative is made quite regular by the addition of a suitable proportion of acid. The bath recommended is a mixture of equal parts of a 10% solution of vanadium oxalate crystals (vanadium oxalate 6·5%, excess oxalic acid 73·5%, water 20%) and 2½% solution of potassium ferricyanide; for dense negatives the solution may be further diluted or the potassium ferricyanide omitted. The impermeability to the dye is so much greater with the film hardened with vanadium salts than with gelatin hardened with alum, formalin, or the like, that the latter may be used for reception of the dye picture. This allows quick drying of the print at high temperatures, thus reducing spreading to a minimum, and also allows the use of cheap paper bases, baryta-coated paper, art printing paper, etc. without any further preparation.—B. V. S.

Colouring photographs; Process for ——. Ges. für angew. Photographie m.b.H. G.P. 328,618, 25.9.18.

THE picture is formed in relief either by the use of a developer which hardens the colloid film in proportion to the amount of image formed or by the use of a normal developer followed by a hardening solution which has the same selective action. The unhardened parts may then be washed away before staining, or the film may be treated with dyes which stain the unhardened but not the hardened portions.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Mercury fulminate; Reactions of —— with sodium thiosulphate. F. H. and P. V. Dupré. Analyst, 1921, 46, 42—49.

AMMONIA is one of the final products of the reaction between mercury fulminate and sodium thiosulphate, and the equation $Hg(CNO)_2+2Na_2S_2O_3+2H_2O=HgS+2Na_2SO_4+NH_4CNS+CO_2$ is probably correct for the ultimate products; the presence of ammonium thiocyanate is, however, difficult to explain if the second phase of the reaction given by

Marshall (*cf.* Heaven, J., 1918, 143 T) is correct. Boric acid may be used in place of potassium iodide in the determination of mercury fulminate by the thiosulphate reaction, since it is equally efficient in preventing loss of alkalinity due to secondary reactions. The precautions to be adopted in the destruction of waste fulminate by means of thiosulphate solution are described.—W. P. S.

Patents.

Explosives. J. H. Babcock, Assr. to Hooker Electro-Chemical Co. U.S.P. 1,366,048, 18.1.21. Appl., 9.5.18.

A crystalline explosive (m.p. 65°—85° C.) contains dinitro-para- and ortho-dichlorobenzene, the former compound preponderating.—W. J. W.

Potassium chlorate; Process of purifying —— for explosives manufacture. K. W. Jurisch and H. von Schleinitz. G.P. 300,714, 11.4.15.

In order to remove chloride from potassium chlorate crystals, these are first dried, then coarsely ground, and washed.—W. J. W.

XXIII.—ANALYSIS.

Optical pyrometry; Comparison of monochromatic screens for ——. W. E. Forsythe. J. Opt. Soc. Amer., 1921, 5, 84—95.

Detailed results of an investigation are given concerning the suitability of glass screens of different colours in monochromatic optical pyrometry. Two thicknesses each of blue uviol glass, Corning green glass, and Jena red glass were employed, the respective total thicknesses being 3·9 mm., 5·2 mm., and 3·8 mm. The transmission curves and the respective effective wave lengths for the various glasses at different temperatures are given. Using the different coloured glasses as screens, determinations were made by different observers of temperatures ranging from 1245° K to 2154° K, employing an optical pyrometer of the disappearing-filament type. The results indicate that throughout the range of temperatures employed, red and green screens are to be preferred to a blue screen. There was very little to choose between the red and green screens. For temperatures below 1200° K, a red screen is the best. For temperatures of about 1400° K, readings can be made with either a red or green screen with accuracy of setting somewhat greater than 0·1%. The error of setting in the case of the blue screen was about 0·3—0·4%. The following reasons are advanced for the choice of a red screen. With a red screen, readings can be made at a lower temperature than with green or blue screens. The rate of colour change with wave length is much less in the red portion of the spectrum than in the green. The spectral transmission of the red screen ends with a steeper slope than does that of the green screen. When employing a rotating sector or absorbing glass for measuring a high temperature, the transmission of the sector or absorbing glass that must be employed is larger for the longer wave length than for the shorter wave length.—J. S. G. T.

Viscosimeter; Simple form of ——. H. Mallison. Chem.-Zeit., 1921, 45, 135.

An apparatus for the rapid determination of comparative viscosities of oils, varnishes, etc., when exact results are not required and the amount of the sample is limited, consists of a set of tubes supported in a frame so that they can be quickly turned from a vertical to a nearly horizontal position. The oil to be examined is placed in one of the tubes, and another control tube is filled with an oil of known viscosity, and after turning the frame to the nearly horizontal position, the rates of flow of the oil streams are compared.—A. de W.

Indicator properties of two new phthaleins (1.2.3-xylenolphthalein and ortho-α-naphtholphthalein). W. Csányi. Z. Elektrochem., 1921, 27, 64—68.

The phthalein from 1.2.3-xylenol and phthalic anhydride should prove a useful indicator for a range of hydrogen-ion concentration on the alkali side corresponding with that covered by methyl orange on the acid side. The change from colourless to blue is completed in the narrow range between $p_H = 8·9$ and 10·2. The colour of the indicator is unaffected by excess of alkali or by alcohol. The phthalein from α-naphthol, on the other hand, though it would serve as an indicator for approximately the same range of hydrogen-ion concentration, shows a less sharp colour change and is decolorised by excess of alkali. Its slight solubility in water and alcohol also diminishes its value as an indicator.—E. H. R.

Hydrogen-ion concentration; Determination of —— by the colorimetric method and an apparatus for rapid and accurate work. E. Van Alstine. Soil Sci., 1920, 10, 467—479.

An apparatus is described for use where a large number of determinations of hydrogen-ion concentration of various solutions are necessary. It is adapted for use with the double-tube standards of Gillespie (Soil Sci., 1920, 9, 115—136; *cf.* J., 1920, 530 A). A graph is given by the aid of which a double-tube colour standard for any p_H value can be easily and quickly prepared.—W. G.

Sodium and potassium ions; Detection of —— in the presence of magnesium ions. E. Ludwig and H. Spirescu. Bul. Soc. Chim. România, 1920, 2, 77—82.

The filtrate obtained after the removal of calcium, strontium, and barium by ammonium carbonate or oxalate is evaporated to dryness, and the residue ignited. One portion of the residue is examined for magnesium in the usual way. Another small portion is added to a drop of a solution containing copper acetate, lead acetate, acetic acid, and sodium nitrite on a microscope slide. The appearance of a black precipitate consisting of cubic crystals of the complex nitrite, $K_2CuPb(NO_2)_6$, indicates the presence of potassium ions. A third small portion of the residue is added to a drop of a concentrated solution of potassium carbonate on a slide and the liquid is evaporated to dryness. To this residue a drop of a solution of potassium pyroantimonate is added. The appearance of a characteristic crystalline precipitate of sodium pyroantimonate indicates the presence of sodium.
—W. G.

Hydrogen ion concentration at which iron is precipitated from hydrochloric acid solution by ammonia, sodium hydroxide, and hydrogen sulphide. H. E. Patten and G. H. Mains. J. Assoc. Off. Agric. Chem., 1920, 4, 233—234.

When a dilute solution of iron in hydrochloric acid is treated with ammonia, sodium hydroxide, or hydrogen sulphide, the first formation of ferrous sulphide or of colloidal ferric hydroxide occurs when the hydrogen ion concentration is slightly above p_H 3·3.—W. P. S.

Iron and manganese; Separation and determination of ——. C. Kollo. Bul. Soc. Chim. România, 1920, 2, 89—95.

For the estimation of iron and manganese in the presence of one another the mixture of salts is dissolved in a little water, acidified, and the iron completely oxidised to the ferric state by means of hydrogen peroxide. The iron is then precipitated as ferric hydroxide by the addition of an excess of a 10% solution of hexamethylenetetramine. The

precipitate is filtered off, dried, ignited, and weighed as ferric oxide. The filtrate is evaporated to dryness, and the residue evaporated with a small quantity of strong sulphuric acid, then ignited, and the manganese weighed as manganous sulphate.
—W. G.

Cations of the group: Ag, Pb, Hg; Detection and identification of the ——. C. Kollo. Bul. Soc. Chim. România, 1920, **2**, 95—99.

MERCUROUS mercury is tested for by the addition of hydrochloric acid to a small portion of the solution, the precipitate being collected on a filter paper and a drop of ammonia added. To the bulk of the solution hydrochloric acid is added, and chlorine is bubbled through until the whole of the mercurous chloride is converted into soluble mercuric chloride. The precipitated lead and silver chlorides are filtered off and separated by dissolving the lead chloride in aqueous sodium hydroxide. In the filtrate the presence of lead is confirmed by the addition of acetic acid and potassium iodide. The presence of silver is confirmed by warming the precipitate left after solution of the lead chloride with a little dextrose and observing the reduction.
—W. G.

Nickel and cobalt; Qualitative and quantitative determination of ——. M. Matsui and T. Nakazawa. Mem. Coll. Sci., Kyoto, 1920, **4**, 265—271.

NICKEL hydroxide reacts directly with a 1% alcoholic solution of dimethylglyoxime. In presence of other hydroxides nickel may be detected by boiling the mixture for a short time with excess of dimethylglyoxime solution, diluting considerably with water, cooling, and shaking with ether. On standing, the nickel dimethylglyoxime floats up with the ether. Cobalt dimethylglyoxime may be detected in solution by adding a drop or two of yellow ammonium sulphide solution, when a very intense red colour is produced if cobalt is present. The test is very delicate if a large excess of dimethylglyoxime is used, but, since ferrous dimethylglyoxime also gives a red colour, iron must not be present. Both nickel- and cobalt-dimethylglyoximes can be electrolysed in alkaline solution, and the metal can be thus determined with accuracy. It is possible to separate the two metals in the usual way with dimethylglyoxime and then determine each separately by electrolysis. The solution should contain 0·02—0·05 g. of the metal in 10 c.c. of electrolyte (0·2 g. of dimethylglyoxime and 5·5 g. of caustic soda for Ni or 6·5 g. for Co per 100 c.c.). The electrolysis should take place below 50 mins., using 800 rotations, with a current of 3·5 amps. at 3·8—4·0 volts for nickel and 4·0—4·5 volts for cobalt.—E. H. R.

Micro-analyses; Weighing of the precipitation vessel with the precipitate in quantitative ——. *Two methods based on this principle.* E. Gartner. Monatsh., 1920, **41**, 477—498.

Two methods are described which permit of the estimation of precipitates weighing 2—15 mg. with sufficient accuracy, the only requisites being a Kuhlmann microchemical balance and such simple apparatus as is easily constructed in the laboratory. In either case the whole of the operations, comprising the weighing of the substance to be analysed, the precipitation, and the weighing of the precipitate, are carried out in a single vessel, this being either an asbestos filter-tube or a pointed centrifuge tube. A tare 1—2 mg. less in weight than the vessel is prepared, the three necessary weighings then requiring only the tare, 1-cg. weight, and the rider. Adhesion of the precipitate to the wall of the vessel causes no error, and both procedures are found to give accurate results.—T. H. P.

Mercury; Separation of —— *from other elements by distillation from hydrochloric acid solution.* W. Strecker and K. Conradt. Ber., 1920, **53**, 2113—2127.

MERCURIC chloride distils slowly when a current of hydrochloric acid gas is passed through its boiling aqueous solution, but the rate of distillation can be greatly accelerated by addition of concentrated sulphuric acid or phosphoric acid, and increasing the temperature. Complete distillation in ½ hr. was obtained by passing a current of hydrochloric acid gas through a sulphuric acid solution of mercuric chloride at 160°—170° C., whilst a mixture of concentrated hydrochloric acid with 10% aqueous hydrobromic acid was dropped into the distillation flask. It was subsequently found that in place of the current of hydrochloric acid gas a stream of air or nitrogen can be used, its action being purely mechanical; and, when phosphoric acid was used, complete distillation was obtained in 1 hr. by merely dropping water into the distillation flask at 150°—160° C. The above distillation process was used for the separation of mercury from copper, cadmium, lead, iron, barium, and other metals. In the case of lead it is better to use phosphoric rather than sulphuric acid, since lead sulphate encloses the mercuric chloride and retards the distillation. Separation from bismuth was incomplete, because the chloride of this element is volatile to some extent. (*Cf.* J.C.S., Jan.)—E. H. R.

Perchloric acid as a dehydrating agent in the determination of silica. H. H. Willard and W. E. Cake. J. Amer. Chem. Soc., 1920, **42**, 2208—2212.

SILICA can be rendered insoluble by boiling with concentrated perchloric acid solution (60 to 70%) for a short time. Less silica remains in the filtrate than by the usual method of evaporating the hydrochloric acid solution to dryness, and the process is far more rapid. The perchlorates formed are dissolved instantly on dilution with water, leaving pure silica uncontaminated by difficultly soluble salts.—J. R. P.

Nitric acid; Gravimetric determination of ——. L. W. Winkler. Z. angew. Chem., 1921, **34**, 46.

THE following procedure is recommended for the determination of nitric acid as nitron nitrate (Busch, J., 1905, 291). 100 c.c. of the neutral solution, containing 0·01—0·05 g. NO_3, is acidified with 1 c.c. of glacial acetic acid, then treated at 60°—70° C. with 10 c.c. of a perfectly clear 10% solution of nitron acetate, and allowed to stand for 24 hrs. in the dark at 15°—20° C. The precipitate is collected on a small pad of cotton wool in a cup-shaped filter, and washed with 50 c.c. of a saturated solution of nitron nitrate at the ordinary temperature. The precipitate is sucked as dry as possible, and dried at 100° C. for 2—3 hrs. Sulphates and iodates are without influence on the results, but chlorides produce small errors, corrections for which are shown in a table.—J. H. L.

Technical gas analysis, based on the measurement of thermal conductivity. M. Möller. Wiss. Veröffentl. Siemens Konzern, 1920, **1**, 147—153. Chem. Zentr., 1921, **92**, II., 210—211.

A METHOD of technical gas analysis, especially for the determination of hydrogen, carbon dioxide, and methane, is based upon the difference in the respective thermal conductivities of certain gases. Carbon monoxide, nitrogen, and oxygen are not differentiated from one another by the method, which is based upon the different cooling effects experienced by two exactly similar heated wires contained respectively within one of two exactly similar very narrow cylindrical metal chambers and surrounded respectively by the gas to be investigated and a standard

gas (*cf.* J., 1920, 470 A, 706 A; 1921, 66 R). Air, or the gas under investigation, freed from the impurities, may be used as standard gas. Convection effects are eliminated as far as possible. The two wires constitute two arms of a Wheatstone network in which a constant electric current is maintained, and the galvanometer scale is calibrated so that the deflection gives directly the percentage of one constituent present. The method is applicable only to gases containing known constituents. With a portable apparatus a determination of hydrogen in air can be made in 2—3 secs. The method can be used for indicating and controlling the combustion in furnaces at a distance.—J. S. G. T.

Carbon dioxide and oxygen in air and flue gas; Indicators for ——. L. H. Milligan, D. O. Crites, and W. S. Wilson. U.S. Bureau of Mines, Tech. Paper 238, 1920. 21 pages.

Apparatus has been devised for the testing of air for carbon dioxide and oxygen and of flue gas for carbon dioxide, which is portable, reasonably accurate, and capable of use by any person without chemical training. The first gives an accuracy of $\pm 0.2\%$ CO_2, and the latter two of $\pm 0.5\%$ CO_2 or O_2. The carbon dioxide indicators are on familiar principles, employing a caustic soda solution as absorbent, but incorporate the following points. The gas is saturated with water vapour by drawing it in through moist cheese cloth. The absorption of carbon dioxide during the taking of the sample is prevented by a layer of Russian "white oil" on the caustic soda in the sample chamber. In the calibration of the scale corrections are made for the aqueous vapour absorbed by caustic soda and for the diminution of pressure due to absorption of carbon dioxide. In the case of flue gas a filtering and cooling arrangement for the gas is provided. In the oxygen apparatus alkaline pyrogallate is used as absorbent, and the air is dried and freed from carbon dioxide by passing through a tube filled with soda lime and calcium chloride. Numerous comparative tests with the indicators and with the Haldane and Orsat apparatus are given.—C. I.

Patents.

Admixture of one gas with others; Indication of the ——, *utilising the change of thermal conductivity occurring in a standard gas by such admixture.* Siemens u. Halske A.-G. G.P. 306,397, 23.4.14.

In a device wherein contamination of one gas with another is ascertained from a comparison of the respective heat losses from a heated wire subjected to the action respectively of the mixture and of a standard gas, the effect of the velocity of the stream of gas upon the indication is allowed for by mounting the heated wire very close to the walls of its containing chamber. The small residual effect of the velocity of the gas stream can be compensated by causing the standard gas to circulate in a closed space.—J. S. G. T.

Gaseous mixtures; Process and apparatus for the continuous determination of constituents of —— *by the method of absorption.* A. Schneider. G.P. 323,975, 3.4.17.

The gas to be analysed is passed, at constant temperature, into a vessel of constant volume, and when a definite pressure is attained therein a tap is automatcally turned so that a definite constant fraction of the gas is transferred to an absorption vessel, where a constituent of the gas mixture is absorbed and its amount determined. The tap is operated by an electrical contact device.

Potter and Robinson. Manufacture of chromium compounds. 6690. Mar. 1.
Stohr. Manufacture of ferruginous preparations. 6786. Mar. 1. (Austria, 9.3.20.)
Tulloch. 6026. *See* I.

Complete Specifications Accepted.

23,318 (1919). Evans and Evans. *See* X.
28,355 (1919). Kelly and Jones. Preparation of alkali pentaborates direct from boron ores. (158,992.) Mar. 2.
29,303 (1919). New Jersey Zinc Co. Production of metal oxides and other compounds of metals. (147,530.) Mar. 9.
30,075 (1919). Pascal. Manufacture of liquid sulphurous acid from dilute sulphurous acid gas. (159,337.) Mar. 9.
30,090 (1919). General Chemical Co. Production of oxides of nitrogen. (136,158.) Mar. 9.
30,177 (1919). Maass. *See* I.
1712 (1920). Sieurin. Production of aluminium oxide from aluminium chloride. (159,086.) Mar. 2.

VIII.—GLASS; CERAMICS.

Applications.

Hailwood. Glass manufacture. 7149. Mar. 5.
Pilkington, and Pilkington Bros. Apparatus for gathering glass from molten mass. 6984. Mar. 3.
Rashleigh. Means for drying clay etc. 6806. Mar. 1.

Complete Specification Accepted.

14,371 (1920). Danner. Forming sheet glass. (159,114.) Mar. 2.

IX.—BUILDING MATERIALS.

Applications.

Dagnall. Heat-insulation or fireproof bricks, tiles, etc. 6563. Feb. 28.
Laube. Wood-preserving method. 6399. Feb. 25. (Ger., 28.2.20.)
Pearson. Manufacture of material for road etc. surfaces. 7141. Mar. 4.
Sanguinetti. 7008. *See* II.
Strehler. Manufacture of artificial stone. 6673. Feb. 28.

Complete Specifications Accepted.

22,588 (1919). Hughes, Brown, and Hill-Jones, Ltd. Manufacture of bricks, slabs, tiles, etc. (159,239.) Mar. 9.
6057 (1920). McLay. Heat non-conducting compositions. (159,411.) Mar. 9.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Angel. Treatment and reduction of sulphide refractory etc. ores. 6232. Feb. 24.
Basset. Manufacture and refining of iron and steel. 6277. Feb. 24. (Fr., 24.2.20.)
Eustis. 6783–4. *See* VII.
Hardy and Stephenson. Siemens etc. furnaces. 7041. Mar. 3.
Morgan Crucible Co., and Speirs. Electrically heated melting etc. furnaces. 6912. Mar. 2.
Passalacqua. Soldering aluminium. 6412. Feb. 25. (Fr., 28.2.20.)
Perkins. Treatment of oxidised ores. 5899. Feb. 21.
Platt. Metallurgical etc. furnaces. 6291. Feb. 24.
Soc. Gén. d'Evaporation. Apparatus for leaching minerals. 5889. Feb. 21. (Fr., 30.3.20.)
White (American Smelting and Refining Co.). Treatment of tin. 6299. Feb. 24.

Complete Specifications Accepted.

2690 (1914) Zavelberg. Roasting-furnaces. Mar. 9.
23,318 (1919). Evans and Evans. Recovery of tin and zinc chloride from tin pot skimmings. (158,926.) Mar. 2.
28,546 (1919) and 6733 (1920). Hurst and Ball. Aluminium alloys. (159,008.) Mar. 2.
28,763 and 30,472 (1919). Ballantine. Production of ferro-alloys. (159,280.) Mar. 9.
28,999 (1919). Taylor and Partington. Treatment of ores etc. by flotation. (159,025.) Mar. 2.
30,951 (1919). Collins. Winning of tin. (159,071). Mar. 2.
31,814 (1919). Storen and Johanson. Treating magnetic or weakly magnetic iron ore containing magnetic ferrous sulphide. (159,380.) Mar. 9.
6912 (1920). Metallind. Schiele u. Bruchsaler. Increasing resistance of aluminium to acid and alkaline liquids. (140,069.) Mar. 9.
8213 (1920). British Thomson-Houston Co. (General Electric Co.). Surface treatment of metals. (159,102.) Mar. 2.
14,794 (1920). Tyrrell. Briquetting ores. (144,276.) Mar. 2.
20,633 (1920). Deuts. Maschinenfabrik. *See* I.

XI.—ELECTRO-CHEMISTRY.

Applications.

Chloride Electrical Storage Co., and Heap. Storage batteries or accumulators. 6137–8. Feb. 23.
Chloride Electrical Storage Co. (Ford). Storage batteries or accumulators. 6655 and 6759. Feb. 28 and Mar. 1.
Collins. Electrolysis of brine. 7200. Mar. 5.
Imbery. Electric furnaces. 6595. Feb. 28.
Morgan Crucible Co., and Spiers. 6912. *See* X.
Reid. Electric furnaces. 6011. Feb. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

3583 (1917). Schuster. Galvanic cells. (158,911.) Mar. 2.

28,154 (1919). Mond (Internat. Precipitation Co.). Apparatus for electrical treatment of gases. (158,982.) Mar. 2.

7944 (1920). British Thomson-Houston Co. (General Electric Co.). Compositions for insulating and protecting electrical apparatus etc. (159,421.) Mar. 9.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Douglas and Sons, and Nicol. Treatment of edible fats. 6787. Mar. 1.

Gill (Sharples Speciality Co.). 6959. *See* I.

Henkel u. Co. Treatment of liquid soaps etc. 6670. Feb. 28. (Ger., 16.12.20.)

Kayser. Refining vegetable oils. 6648. Feb. 28.

COMPLETE SPECIFICATIONS ACCEPTED.

23,585 (1919). Erslev. Cooling or allowing to crystallise concentrated fatty emulsions. (134,815.) Mar. 9.

29,781 (1919). Melton and Downs. Recovering and utilising solvent from the air from apparatus for extracting oil, fat, etc. (159,039.) Mar. 2.

599 (1920). Townsend. Soap. (159,083.) Mar. 2.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATION.

Kilburn (Titanium Pigment Co.). Manufacture of composite titanic oxide products. 6618. Feb. 28.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Bilbrough. Manufacture of pure or filled rubber from latex. 6737. Mar. 1.

Davidson. Treatment of latex. 6041. Feb. 22.

COMPLETE SPECIFICATIONS ACCEPTED.

28,593 (1919). Perkin, Mandleberg, and Mandleberg and Co. Compositions containing india-rubber. (159,014.) Mar. 2.

10,829 (1920). Davidson. Treatment of raw rubber when freshly coagulated from latex. (159,106.) Mar. 2.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Beretta. Tanning arrangement for hides etc. 5860. Feb. 21. (Ital., 20.2.20.)

Carmichael and Ockleston. Tanning. 6221. Feb. 24.

Hell. Tanning hides etc. 6798. Mar. 1.

Renck. 6697. *See* VI.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Desmond and Tisdall. Fertiliser. 6765. Mar. 1.

Lo Monaco. Chemical fertilisers. 6434. Feb. 25. (Ital., 26.2.20.)

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Crawford. Fermentation of alcoholic beverages. 6700. Mar. 1.

Gilmour. Manufacture of yeast. 6107. Feb. 23.

Jensen (Corby). Making, treating, and preparing yeast. 6636. Feb. 28.

Kashiwaga. Preparation of diastase or a solution of diastase. 6235. Feb. 24.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Apsley. Apparatus for treating sewage etc. 7076. Mar. 4.

Boldy and Waite. Machines for separating solid matter from trade effluent etc. 6474. Feb. 26.

Brunet, and Soc. Anon. Maison Detilleux. Disinfecting or sterilising. 7222. Mar. 5.

Carpmael (Bayer u. Co.). Disinfecting, insecticidal, and fungicidal compositions. 6419. Feb. 25.

Corn Products Refining Co. Separating gluten from starch. 7024. Mar. 3. (U.S., 8.3.20.)

Dorr Co. Treatment of sewage. 7219. Mar. 5. (U.S., 27.3.20.)

Douglas and Sons, and Nicol. 6787. *See* XII.

Raimbert. Sand filters. 5883. Feb. 21. (Fr., 23.3.20.)

Spear and Spear. Manufacture of food products. 5879. Feb. 21.

Wanklyn. Treatment of germ of cereals. 6830. Mar. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

16,189 (1919). Greville. Treatment of flour. 158,917.) Mar. 2.

29,245 (1919). Nicholson. Extraction of juices, pectin, etc. from fruit etc. (159,311.) Mar. 9.

30,978 (1919). Townsend. Milk food. (159,362.) Mar. 9.

980, 1112, and 1115 (1920). Niessen. Boiling and drying organic substances, particularly offal. (137,828, 137,841, 137,844.) Mar. 2 and 9.

18,852 (1920). Sykes. Apparatus for dehydrating food products. (146,917.) Mar. 2.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Carpmael (Bayer u. Co.). Manufacture of ethylene derivatives. 6160. Feb. 23.

Elektro-Osmose A.-G. Manufacture of swine-fever serum. 6531. Feb. 26. (Ger., 27.2.20.)

Soc. Chim. Usines du Rhône. Manufacture of oxyaldehydes and their derivatives. 6289, 6450. Feb. 24 and 25.

Szarvasy. Manufacture of methyl alcohol from methyl chloride. 7142. Mar. 4. (Hungary, 16.7.14.)

COMPLETE SPECIFICATIONS ACCEPTED.

6209 (1920). Datta. Treatment of waste from growing tea plants and obtaining caffeine. (159,097.) Mar. 2.

13,349 (1920). Lilienfeld. Manufacture of dialkyl sulphates. (143,260.) Mar. 9.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Donisthorpe. Colour photography. 6859. Mar. 2.

Luboshey. X-ray photography. 6901-2. Mar. 2.

XXIII.—ANALYSIS.

APPLICATION.

König. Measuring density of gases. 7162. Mar. 5. (Ger., 5.3.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

30,637 (1920). Siemens u. Halske A.-G. Photometers. (153,323.) Mar. 2.

I.—GENERAL; PLANT; MACHINERY.

Anemometer. Gerdien and Holm. *See* XXIII.

Patents.

Combustion furnace. W. L. Harder, Assr. to Harder Furnace and Engineering Corp. U.S.P. 1,354,741, 5.10.20. Appl., 13.3.19.

Powdered fuel is injected into a furnace between streams of heated air which are independently regulated so that combustion takes place at any desired point in the furnace.—W. F. F.

Surface-condensers; Process of keeping —— free from scale and sludge. Maschinenbau-A.-G. Balcke. E.P. 135,189, 10.11.19. Conv., 19.2.18.

A predetermined quantity of an acid such as hydrochloric, acetic, or formic acid, is added to the cooling water to convert carbonates into easily soluble salts; the process is applicable to condensers (but not to boilers) because the temperatures used are insufficient to cause dissociation of the chlorides or other salts formed. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 2798 of 1874 and 139 of 1911.)—B. M. V.

Evacuating [dangerous] fluid from containers; Method of and apparatus for ——. F. N. Pickett, W. J. Palmer, and G. H. Tatham. E.P. 158,333, 30.10.19.

The container, *e.g.*, a shell containing "mustard gas," is opened by a punch which drives in the soft iron sealing plug, and evacuated by a pipe connected with a source of vacuum. To prevent escape of gas during the operations the shell is inserted through an opening provided with a rubber airtight collar into a chamber in which also a vacuum is maintained, means being provided for operating the punch and emptying pipe without destroying the vacuum. The shell may be held in place by means of an electro-magnet.—B. M. V.

Filters. J. Miller, and G. Fletcher and Co., Ltd. E.P. 158,387, 7.11.19.

A filter which may be used, *e.g.*, for filtering sugar stock through megass, comprises a chamber mounted on hollow trunnions, through which the liquor to be filtered is admitted and exhausted. The chamber is tilted to receive a charge of filtering medium, then placed in a vertical position, and a lid and pressure plate, both supported by an overhead yoke, are lowered respectively upon and into the filter chamber by means of a screw; the pressure plate continues to move downward after the lid has come to rest until the filtering medium is sufficiently compacted. The liquor to be filtered is then pumped through, and should the filtrate not be clear, additional pressure may be applied to the plate without stopping the operation of filtering. —B. M. V.

Filtering apparatus; Arrangement and construction of ——. C. J. Haines. E.P. 158,663, 7.11.19.

Filtering frames, suitable for use in the apparatus described in E.P. 6272 of 1900 and 27,007 of 1903, are constructed of two perforated sheets kept apart by a corrugated sheet and held in place by a cast base and frame of channel section. The perforated sheets may be covered by wire gauze and that in turn by the filtering medium.—B. M. V.

Filter. J. P. Probst. U.S.P. (A) 1,367,324 and (B) 1,367,325, 1.2.21. Appl., 14.2.19 and 12.6.19.

(A) A vertical casing is provided near the top and the bottom with horizontal ridges projecting inwards, each ridge supporting an annular flange. Removable interchangeable supports rest on the flanges and a cylindrical filter screen is mounted on one of the supports. Filtering material is packed in the casing between the bottom of the filter screen and the other support. (B) In a filter of the kind described in (A) liquid passes into an annular space surrounding the casing and thence into a filtering chamber filled with compressed sponges. The liquid then passes into a second chamber within the casing filled with layers of crushed cloth, the second chamber being detachable from the casing. The liquid is discharged through a perforated wall into a second annular space surrounding the second filtering chamber.—W. F. F.

Filter; Metallurgical and chemical ——. H. B. Faber. U.S.P. 1,368,618, 15.2.21. Appl., 3.4.15.

Within an airtight container is a rotary filter in sections, each section having an independent discharge pipe. Means are provided for supplying pressure medium to the container, for supplying cleansing fluid to the solids collected on the filter, and for providing a counter-pressure in excess of the pressure so as to lift all solids from successive portions of the filter during continuous operation without relieving pressure on the filtering portions. By means of a distributing valve the filtrates from the different discharge pipes can be distributed to different receptacles prior to and subsequent to the application of the cleansing fluid.—J. W. D.

Filter-press. M. Neide. G.P. 328,941, 18.4.18.

A filter-press is constituted of a number of alternate filter plates and filter frames in juxtaposition, the whole being disposed within a casing provided with an opening through which the filter frames or plates may be withdrawn or replaced either as a whole or in sections.—J. S. G. T.

Membrane or ultra filters with pores of a definite size; Manufacture of ——. Membrane filters, and process of making them. R. Zsigmondy and W. Bachmann. G.P. (A) 329,060, 5.9.16, and (B) 329,117, 22.8.16.

(A) A solution of a cellulose ester is poured upon plates, or soaked into the pores of textile fabrics or similar material, and is dried in an atmosphere, the relative humidity of which is maintained constant to within a few per cent., the temperature being similarly maintained constant to within a few degrees. Water may be added to the ester before drying, if necessary. A compact filter of small porosity is obtained when the relative humidity employed is low. Employing a higher degree of humidity, the permeability of the resulting filter is increased. The porosity may also be varied by altering the composition of the solvent in which the cellulose ester is dissolved, without altering the concentration of the solution. (B) Membrane filters composed of a cellulose ester and possessing a structure especially adapted for filtration purposes are prepared by using a solvent composed of a mixture of substances in part easily vaporisable and in part vaporisable with difficulty, and submitting the membrane to the action of water and steam. —J. S. G. T.

Metallic filter gauze; Manufacture of ——. J. Rathjen. G.P. 329,061, 3.9.18.

A metal gauze of iron, steel, brass, bronze, copper, etc. is coated with another metal by spraying, in such a way that it retains its permeability. If necessary, the gauze may be coated, either before or after the spraying process, with a metal resistant to acids and alkalis, this metal being deposited electrolytically or otherwise. The gauze may be

A

employed in filter-presses etc. in place of filter cloth, over which it possesses a number of advantages.—J. S. G. T.

Non-flammable volatile liquid. A. Henning. E.P. 158,494, 15.7.20.

ETHYL chloride, with or without methyl chloride, is mixed with methyl bromide and, if desired, colouring or perfuming agents, forming a mixture that will vaporise practically as a whole, and will be useful for refrigerating, as a solvent, and for fire extinguishing.—B. M. V.

Drying apparatus. C. S. Bedford and A. Oldroyd. E.P. 158,734, 20.11.19.

HOT gases (*e.g.*, flue gases from boilers) are passed in two streams through both compartments of a two-storey drying-chamber, through which the material to be dried is conveyed first in one compartment in the same direction as the gases, returning through the other compartment in the opposite direction to the gases.—B. M. V.

Cooking thick masses; Apparatus for ——. E. A. Strohmaier and B. A. Hook. U.S.P. 1,366,431, 25.1.21. Appl., 20.12.17.

A COOKING vessel is provided with a rounded bottom and a steam-heating coil near the bottom. A steam pipe extends vertically downwards into the vessel, and is provided with an ejector nozzle, which discharges a jet against the curved bottom so as to circulate the material around the heating coil. —W. F. F.

Rectifying columns; Apparatus for facilitating the reflux of condensed liquid in ——. C. A. Hartung. G.P. 328,412, 26.6.17.

COLLECTING vessels are arranged below the reflux tubes, and one or more holes are bored in the lower parts of these, affording a restricted outlet for liquid. The holes are of such size that the vessels remain filled under all circumstances.—J. S. G. T.

Distilling column. J. Schneible. U.S.P. 1,366,956, 1.2.21. Appl., 2.8.19.

A DISTILLING column consists of a series of annular sections containing chambers, each chamber having a lower annular baffle plate, and an upper circular baffle plate of smaller diameter carrying a series of depending guide vanes which extend to the lower plate.—W. F. F.

Condenser. Heat exchanger. J. Schneible. U.S.P. 1,366,957—8, 1.2.21. Appl., 2.8.19.

A CONDENSER comprises a series of superposed horizontal cooling coils in a casing, each coil having an annular baffle plate with a large central opening below it, and a baffle plate above it of larger diameter than the diameter of the opening in the plate below. When used as a heat exchanger, the baffle plate above the coil is of larger diameter, and the annular portion lying above the annular plate below the coil is perforated.—W. F. F.

Volatile solvents; Process for the recovery of ——. E. Bindschedler. U.S.P. 1,367,009, 1.2.21. Appl., 18.6.20.

GAS containing solvent vapour is brought into contact first with phenols and then with concentrated sulphuric acid to absorb the solvent vapour, which is subsequently recovered from the absorbents. —W. F. F.

Volatile solvents; Process for the recovery of ——. E. Bindschedler. U.S.P. 1,368,601, 15.2.21. Appl., 28.7.20.

GASES containing a volatile solvent are brought successively into intimate contact with a phenolic liquid to remove the volatile solvent, with an alkaline solution to remove any phenol carried over, and with concentrated sulphuric acid to remove any remaining solvent.—B. M. V.

Separation of organic gases or vapours from admixture with air or other gases; Process for ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 310,092, 4.11.16.

THE gaseous mixture is subjected to the action of extremely porous charcoal, prepared in accordance with G.P. 290,656 (F.P. 471,295; J., 1915, 216), which absorbs 5% of its weight of methane, acetylene, or cyanogen, and 50—70% of its weight of ether, methyl or ethyl alcohol, acetone, benzene, ethyl acetate, or acetic acid. The absorbed gases or vapours are subsequently expelled by heating the charcoal in steam.—J. S. G. T.

Lining metal tanks with hard rubber; Process of ——. E. S. Boyer, Assr. to American Hard Rubber Co. U.S.P. 1,367,231, 1.2.21. Appl., 18.11.20.

THE inner surface of the tank is covered with plastic soft rubber and then with plastic hard rubber, and both layers are vulcanised together and to the tank by the application of steam under pressure. Water under pressure is then introduced into the tank to ensure adhesion during cooling. —W. F. F.

Osmotic diaphragm. E. A. Sperry, Assr. to Anaconda Lead Products Co. U.S.P. 1,368,227, 8.2.21. Appl., 26.12.18.

A POROUS diaphragm for use in a bi-fluid cell is composed of cloth parchmentised to a predetermined extent.—J. S. G. T.

Liquid, pulverulent, or granular substances; Process by which two or more —— *are simultaneously atomised and mixed or enabled to interact.* G. A. Krause. G.P. 302,421, 1.8.16.

THE materials are delivered together on to a rapidly rotating disc within a chamber, and the powdery product is either collected in the chamber or withdrawn therefrom by suction. The process may be used for the production of soap powder, or of tin oxide from stannate liquors.—J. H. L.

Contact masses containing iron, cobalt, nickel, etc. or mixtures thereof, or the oxides; Revivification of ——. Badische Anilin und Soda Fabrik. G.P. 304,341, 9.4.14.

THE contact mass is treated with an aqueous oxidising agent, under such conditions that little, if any, of the contact metal or of the oxide is dissolved. Oxidising acids such as nitric acid, and oxidising salts such as nitrates, chromates, etc., may be employed.—J. S. G. T.

Washing and cooling gases; Multiple-stage disintegrator for ——. F. Trappmann. G.P. 327,047, 9.1.15.

THE gas and water flow alternately in the same and in opposite directions through a multiple-stage disintegrator constituted of two concentric atomising drums rotating in opposite directions within a chamber. The diameters of the drums increase gradually or discontinuously from the inlet to the outlet end of the chamber. The chamber is divided into compartments by a number of transverse circular plates rotating with the atomising drums. The gas passes inwards through the drums towards the axis in one compartment and outwards in the next and so on, and is submitted to an atomising and centrifugal force of progressively increasing magnitude, owing to the increase in the circumferential velocity of the drums in successive compartments. The quantity of water injected into

the various compartments diminishes in proportion as the diameter of the atomising drum therein increases.—J. S. G. T.

Reaction column [for absorption, distillation, rectification, etc.]. Soc. J. Bouchayer et Paris et Cie. G.P. 327,164, 2.4.19.

In a plate column the tubes for the gas or vapour are arranged at the corners of a regular hexagon and the tubes for the liquid at the centres of the hexagons. The tubes for the liquid are each surrounded by a sleeve having narrow vertical slits in the portion between adjacent plates and also broader openings at the bottom. The spaces between successive plates are packed with a filling material up to the level of the upper ends of the vertical slits. Liquid which is carried up mechanically through the filling material by the gas or vapour circulates through the slits into the space enclosed by the sleeve and then out through the broader openings at the bottom, whereby the same portion of liquid comes a number of times into contact with the gas or vapour. The column is intended for use in gas washing, for recovery of ammonia from coke-oven and blast-furnace gas, and for the recovery of vapours of volatile liquids etc.— J. S. G. T.

Electrical purification of gases; Removal of dust precipitated in the ——. H. Zschocke. G.P. 329,062, 28.10.19.

Two concentric tubes, the outer of which is stationary, are employed. To the inner tube, which serves as the electrode on which the dust is precipitated, an oscillatory or/and jerky motion in the direction of its axis is imparted, whereby the dust precipitated is shaken down into a funnel-shaped receptacle.—J. S. G. T.

Gas washers, reaction columns, and the like; Sprinkling device for use in ——. C. Still. G.P. 329,118, 3.8.19.

The washing liquid is distributed by a sprayer or similar device, the pipe for supplying liquid thereto being connected, by means of a branch pipe, with the gas chamber at some distance from the point of mission of the spray. Thereby, owing to suction or injector action, the washing fluid is admixed with gas prior to entering the sprinkler, whereby a much finer spray is obtained.—J. S. G. T.

Separation of solid impurities from gases, vapours, and liquids; Cyclone device for ——. R. Wussow and E. Schierholz. G.P. 329,779, 19.8.19.

The fluid enters and leaves the cyclone tangentially in the direction of rotation of the cyclone about its vertical axis. The cyclone is surrounded by an annular collecting chamber, and the lighter constituents are deposited in a central settling chamber.—J. S. G. T.

Fluids of low boiling point, with the exception of hydrocarbons [e.g., sulphur dioxide and ammonia]; Process for the recovery of —— [from gaseous mixtures]. Apparate-Vertriebs-Ges. m.b.H. G. P. 329,412, 10.5.17.

The gaseous mixture is compressed, then expanded and simultaneously brought into contact with a washing agent. The process is applicable to the recovery of certain constituents, such as sulphur dioxide or ammonia, from gases. In these two cases, the condensed liquid separated by compression, constituted in the one case of a solution of sulphur dioxide and in the other of a solution of ammonia in water, is employed as washing medium, and is sprayed into the expansion chamber. The efficiency of the process is increased by the use of impact or reflecting surfaces to ensure intimate contact between the washing medium and the mist formed during the expansion. In like manner the cooled gas may be passed into a centrifugal washer into which the washing fluid is sprayed.—J. S. G. T.

Separation of bubbles and drops of liquid from the vapours rising from boiling liquids; Process for the ——. B. Graemiger. G.P. 329,719, 31.7.19.

The vapour rising from the boiling liquid is made to percolate through a vaporous mist moving with much higher velocity, whereby drops of liquid in the vapour are precipitated.—J. S. G. T.

Crushing ores and other material; Apparatus for ——. H. W. Hardinge. U.S.P. 1,367,777, 8.2.21. Appl., 6.2.19.

See E.P. 148,637 of 1919; J., 1920, 619 a.

Recuperators for use in connection with furnaces. H. Hecker, and Bender und Främbs G.m.b.H. E.P. 133,045, 24.9.19. Conv., 2.5.18.

Cooling apparatus. G.P. 329,479. *See* VII.

Leaching. E.P. 158,320. *See* X.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Assay of —— for carbonisation purposes. T. Gray and J. G. King. Tech. Paper No. 1, Fuel Research Board, 1921, 13pp.

The coal sample is ground to pass through a 60-mesh sieve, and is dried at 105°—110° C. The retort consists of a horizontal hard glass or silica tube 30 cm. long and 2 cm. diam., and is fitted with a side tube leading into a U-tube which acts as a condenser for oil and water. This is connected with a second tube charged with glass beads drenched with sulphuric acid for the absorption of ammonia. The gases are collected in a gas-holder fitted with a constant pressure device. About 20 g. of the coal is placed in the tube, and after all connexions have been made the furnace, previously heated to 300° C., is pushed into position round the retort. As soon as the evolution of the gas occluded by the coal and of the expanded air stops, the temperature of the furnace is gradually raised so that the final temperature, 550° C. to 600° C., is reached in 1 hr. Observations are made of the temperatures at which water and oil appear. Heating at the final temperature is continued for 1 hr. Weighings are made of the coke and oils, and the liquor and gas volumes are measured. The method has been found to give concordant results.—W. P.

Lignite and lignite-coal mixtures; Carbonisation of ——. A. Viehoff and E. Czakó. J. Gasbeleucht., 1920, **63**, 379—383.

Results are given of the experimental carbonisation of four coals, two of which were lignites whilst two were typical brown coals. Details are given of the composition of the coals, together with a comparison of the velocity of carbonisation of the coals and of bituminous coal from the Saar basin. During the first half hour of heating there was an evolution of hydrogen sulphide amounting to 8% by volume of the gas produced, which rapidly fell to 2% at the end of 1¼ hrs. The ammonia was also evolved very rapidly at first and the yield fell quickly in the same way, accompanied by a diminution in the percentage of carbon dioxide evolved. The residual coke was of the nature of breeze, and was very difficult to quench. It had a calorific value of 4460 to 5947 Cals. per kg. In the tests with mixtures of lignite and bituminous coal, it was found that better results were obtained when the lignite was intimately mixed with the coal by shovelling than when no special care was taken to obtain good admixture. Such careful ad-

mixture is, however, almost impossible in practice. Further, the coke gave less fines when "nut" coal was used than when coal with particles of widely differing sizes was employed.—A. G.

Coal gas; Composition of —— in relation to its utilisation. R. V. Wheeler. Sheffield Gas Consumers' Assoc. Gas J., 1921, **153**, 615—618.

THE character of the flame of a Bunsen burner, which is the type of burner employed in most heating appliances, is entirely dependent on the speed of propagation of flame in the mixture of gas and air that is issuing at the mouth of the burner, and this speed of propagation of flame varies with the composition of the mixture and with the nature of the combustible gas (J., 1920, 94 A, 95 A, 181 A). Speed percentage curves for different gases can be made use of to see how the character of the flame may vary with different gas mixtures. The maximum speed of flame that can be obtained with a given combustible gas and air gives a measure of the tendency of that gas to back-fire. The magnitude of the range of mixtures of a given gas with air lying between the fastest speed mixture and the upper limit mixture gives a measure of the "adjustability" of the gas, and the steepness of the slope of the speed percentage curve on the high-limit side gives a measure of the "adaptability" or ease of adjustment of the gas. There is no reason, on the score of an adaptable mixture of the gas, for trying to place limits on the proportions of combustible gases present in town's gas. The presence of nitrogen, however, has an adverse effect on the ease of adjustment of the gas-air mixture. Large proportions of incombustible gases result in a small margin of adjustment, so that slight variations in the pressure of the gas will cause wide fluctuations in the character of the flame and in the distribution of heat throughout it, with consequent inefficiency of the furnace.—W. P.

Technical gases; Content of water vapour in ——. G. Sailer. Feuerungstech., 1920, **9**, 88—89.

THE author emphasises the importance of estimating the content of water vapour in industrial gases, especially producer-gas. The gas is filtered to remove soot, tar, etc., and then passed through a U-tube filled with calcium chloride or phosphorus pentoxide. Any moisture deposited in the filter tube is estimated by subsequently drying this tube in an air oven and determining the loss in weight. When gases have been washed by a water spray, small globules of water often remain suspended in the gas in an atomised condition, and if a moisture determination is made, it can easily be decided whether free water is present or whether the gas is merely saturated with water vapour.—A. G.

Water-gas. L. Vignon. Ann. Chim., 1921, **15**, 42—60.

THE mineral matter, and in particular lime, present in coke plays an important part in the composition of the water-gas produced from it. Below 800° C. the formation of calcium carbonate is an important factor in the production of methane. Above 900° C. the carbonate is decomposed, and the calcium oxide formed acts catalytically, favouring the three reactions: $4CO+2H_2O=3CO_2+CH_4$; $2CO+2H_2=CO_2+CH_4$; $CO_2+4H_2=CH_4+2H_2O$. It is possible by the action of lime to convert carbon monoxide into hydrogen and a mixture of hydrocarbons. Other substances may act as catalysts favouring the interaction of carbon monoxide and water vapour to give methane. With certain of these catalysts (iron, alumina, silica) there is probably an intermediate formation of a carbide, which is decomposed by the water vapour. In other cases hydrogen may be formed, and this then reacts, as above, with the carbon monoxide or dioxide to give methane. It should thus be possible to prepare a gas approaching coal gas in composition. Water-gas in contact with lime and in the presence of a suitable amount of water vapour at 400° C. gives a gas containing H_2 85—90%, CH_4 5—10%, CO 0—5%. By passing steam over a mixture of coke and lime at 600°—1000° C. a gas containing H_2 80—85%, CH_4 15—20%, CO 0—5% can be obtained. By mixing coal with lime and distilling at 900°—950° C. and then passing sufficient steam over the residual coke at 900°—1000° C. the total gas may have the composition H_2 70—78%, CH_4 15—20%, CO 5—10%. By suitably regulating the reaction the percentage of CO may be reduced to zero.—W. G.

Carbon monoxide in air and in flue gases; Determination of small amounts of ——. D. Florentin and H. Vandenberghe. Comptes rend., 1921, **172**, 391—393.

GAUTIER'S iodic anhydride method (J., 1898, 490, 603) has the disadvantage that other gases are liable to be present which are also capable of reducing this anhydride. Certain precautions with reference to the apparatus and its manipulation are indicated. The method of Ogier and Kohn-Abrest (Ann. Chim. Analyt., 1908, 169, 218), in which the amount of gas, deprived of oxygen, necessary to cause the appearance of the characteristic absorption bands of carboxyhæmoglobin is determined, gave concordant results. The authors recommend each analyst to prepare his own scale. If the gas contains more than 1 pt. of carbon monoxide per 1000, it should be diluted before analysis.—W. G.

Oil shale; Laboratory testing of —— for oil and ammonia yield. E. L. Lomax and F. G. P. Remfrey. J. Inst. Pet. Tech., 1921, **7**, 34—47.

Oil.—One kg. is placed in a horizontal iron tube, 20 in. long and 3 in. diam., one end of which is connected with a source of superheated steam, whilst the other end connects with a condenser, a closed receiver, a second condenser, absorption vessels (gas scrubbers), and a graduated aspirator (for measuring gas yield). The iron tube is heated, and as soon as water commences to distil, steam at 180° C. is admitted, and the heating is increased gradually so as to maintain a steady distillation of the oil; when distillation ceases the tube is heated to dull redness for a short time. The distilled oil is examined as to its sp. gr., solidifying point, sulphur content, moisture content, and fractionation. The heavier fractions (above 150° C.) are distilled with the aid of superheated steam. *Ammonia.*—The same apparatus is used, but the shale is placed in the middle portion of the iron tube, the two ends being filled with ignited broken firebrick. The ends of the tube are first heated to dull redness, steam at 180° C. is then admitted, and the whole tube is brought rapidly to a dull red heat; this procedure produces but little oil and a large volume of gas. The vapours are condensed and absorbed in dilute sulphuric acid contained in the receiver and scrubbers, and at the end of the operation the contents of these are mixed and the amount of ammonia determined in the usual way.
—W. P. S.

Gasoline by the charcoal absorption process. G. A. Burrell, G. G. Oberfell, and C. L. Voress. Chem. and Met. Eng., 1921, **24**, 156—160.

A RECENT method for the extraction of gasoline from natural gas is described in which the gas is passed over activated charcoal until absorption is complete, when the gas is replaced by a current of superheated steam to expel the absorbed liquid constituents of the gas. Coconut shell charcoal activated by the steam activation process is the best for the process and should be in granules from 8- to 14-mesh. An advantage of the process is that the

charcoal exhibits "selective" absorption, *i.e.*, when the gas is first passed through, the lighter fractions such as ethane, propane, butane, etc., are absorbed, but as absorption proceeds these constituents are replaced by heavier fractions, and thus the quality of the product can be varied by regulating the extent of the absorption. When the gas first comes in contact with the charcoal the temperature rises owing to the liberation of the latent heat of the condensed vapours, but after a few minutes the rise ceases although absorption is not complete, the heat being utilised to volatilise the lighter fractions condensed previously. In the case of a gas rich in gasoline the temperature rise may be as much as 60° C., and if the gas is passed through a column of the charcoal, a zone at the raised temperature gradually passes along the column in the direction of the gas. The temperature of the inflowing gas has a marked effect on the efficiency of absorption; if the gas is at 10° C. there is 100% absorption, and the absorption decreases constantly as the temperature rises to 300° C., above which there is no absorption at all. The rate of absorption depends upon the richness of the gas; with a gas giving 400 galls. of gasoline per 1,000,000 cub. ft., a gas supply of 40 cub. ft. per hr. per sq. in. of base surface in a 5 ft. column of charcoal is not too high, and gives a back pressure of 1 to 2 lb. After absorption is complete it is necessary to heat the charcoal to at least 200° C. to expel the heavier fractions of the gasoline, and the steam employed for the purpose should be superheated to 250° C. or higher. The vapour is preferbly passed through two condensers in series: in he first, just sufficient cooling water is employed o condense the greater part of the steam just below 00° C.; in the second, condensation is completed y the use of an efficient supply of cooling water at bout 15° C. The steam distillation does not imair the absorptive property of the charcoal. In omparative tests run on the same days, an oil lant and a charcoal plant extracted respectively 25 and 203 galls. of gasoline per 1,000,000 cub. ft. rom the same gas.—L. A. C.

ulphur in benzine [petroleum spirit]; Lamp method for determining ——. A modified form of apparatus. J. S. Jackson and A. W. Richardson. J. Inst. Pet. Tech., 1921, 7, 26—34.

n the lamp described, the ordinary wick is replaced by a bundle of capillaries which are 'spread" by a central air tube lightly jammed nto position; the air supply does not pass through he benzine, so that fractionation is greatly reluced, and the current of air escaping from the top f the air tube produces a slight reduction in presure, thus assisting the action of the capillaries nd enabling them to supply sufficient benzine to naintain a strong non-luminous flame. A mixing hamber is provided above the tops of the capiliaries and the luminosity and size of the flame are ontrolled by the air supply.—W. P. S.

etroleum spirit; Analysis of ——. Critical temperature of solution of hydrocarbons in aniline. N. Chercheffsky. Ann. Chim. Analyt., 1921, 3, 53—55.

he method described by Chavanne and Simon (J., 919, 619 a, 672 a) has been published previously by he author (J., 1910, 681).—W. P. S.

Patents.

Suction gas generators. W. E. Scrivner, Assee. of S. Phillips. E.P. 132,269, 6.9.19. Conv., 6.9.18.

The fuel feed hopper and the generator body are made of stout galvanised iron, the generator being lined with asbestos, with an inner course of firebrick in the furnace zone. A galvanised iron wire is coiled spirally round the generator body and welded to it; a stream of water is fed on to the wire spiral to generate steam. Fuel is supplied through a central depending shoot, concentric with the furnace, and the gases are taken off from a side pipe in the cowl, of which the hopper forms a part. —A. G.

Blue water-gas; Plant for the manufacture of —— in conjunction with coal gas. J. Lowe. E.P. 149,928, 2.12.19. Conv., 19.8.19.

Blue water-gas is made in twin generators, so arranged that whilst one is being blown with steam the other is being blown with air. The blue water-gas is either passed into coal being carbonised in the retorts of a separate installation or is mixed with coal gas in the gas main.—A. G.

Combustion gases of a fuel; Apparatus for utilising the —— for generating steam mixed with these gases and, if desired, a percentage of pure steam. F. H. E. Marden. E.P. 158,326, 29.10.19.

Liquid fuel is sprayed at high pressure into a vaporiser, where it is mixed with compressed air supplied through a non-return valve. The mixture is ignited by an electric spark and the gases of combustion pass through headers and side-tubes surrounded by water, which thus becomes heated. The vertical side-tubes are open at the end and project above the water level; the gases of combustion can thus be mixed with the steam generated. By means of a by-pass, the hot gases can be passed into an ordinary fire-tube boiler, thus generating steam unmixed with the products of combustion.—A. G.

Producer gas plants; Generators for ——. T. H. White. E.P. 158,409, 14.11.19.

The producer comprises a combustion chamber of rectangular cross-section, the coke being supported by fire-bars and a superimposed cylindrical structure. The ratio of the area of the grate or complete combustion chamber to that of the superposed converter chamber is 2·8 to 1. It is claimed that clinkering is largely reduced with such a plant. —A. G.

Combustible gaseous compositions especially for use in cutting, welding, and the like. R. H. Brownlee and R. H. Uhlinger. E.P. 158,633, 5.11.19.

A suitable gaseous fuel for the purpose specified consists of over 75% of hydrogen, over 5% of hydrocarbon, and not more than 10% of carbon monoxide. For special purposes, and where it is desired to avoid oxidation of the metal, the gas may consist of about 87% of hydrogen, about 9% of hydrocarbon, and 4% of carbon monoxide.—A. G.

Gas [from garbage]; Process for making ——. J. U. McDonald. U.S.P. 1,367,321, 1.2.21. Appl., 10.3.20.

Wet garbage is placed in a vertical retort and heated at an intermediate zone so that it is carbonised and rendered incandescent at that point. The moisture and gas distilled from the upper layers pass down through the incandescent zone, and all the combustible constituents are thereby converted into fixed gas.—W. F. F.

Gas producer for obtaining low temperature tar. Deutscher Industrie-Ofenbau, G.m.b.H. G.P. 327,095, 31.8.17.

The distillation gases are withdrawn through a central gas outlet pipe fixed to the revolving grate. They enter the upper end of the outlet pipe, within the producer shaft, through a perforated hood provided with sloping metal plates between the perforations.—C. A. C.

Gases; Collection of —— in chambers. C. C. Carpenter. E.P. 158,758, 3.12.19.

To ensure uniformity of composition of the contents of a gas-holder, a portion of the gas is withdrawn to a compressor and is re-introduced through a nozzle, forming an injector, thus producing thorough agitation of the contents of the holder. —A. G.

Hydrocarbons; Process for converting higher molecular —— into lower molecular ones. Naaml. Vennoots. Nederlandsche Lichte Olie Maatschappij, Assees. of N. V. Hollandsche Benzol en Benzine Maatschappij. E.P. 135,197, 12.11.19. Conv., 12.11.18.

A mixture of high-molecular hydrocarbon (tar oil or petroleum) vapour and superheated steam is passed up a vertical retort packed with coke or the like to the extent of ½ to ⅔ of its height. The retort is heated externally so that the middle zone of the packing material is maintained at 500°—1200° C., while the top and bottom zones are heated to a temperature 300° C. lower than that of the middle zone, the height of which is from ⅓ to ½ of the total height of the retort.—L. A. C.

Fatty acids from hydrocarbons. G.P. 307,048. *See* XII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood distillation. III. Distillation of some Mysore and Baroda woods and of certain waste products. J. J. Sudborough, H. E. Watson, M. N. Bahuguna, K. R. Dotiwala, M. G. Kekre, M. O. Krishnaswamy, M. K. Narasimhan, and S. M. Nilikani. J. Indian Inst. Sci., 1920, 3, 281—292.

The distillation of a further 23 species of Mysore woods and 8 species of Baroda woods gave results similar to those previously obtained (*cf.* J., 1920, 327 A), *i.e.*, the yields of acetic acid and methyl alcohol were generally lower than those obtained on distilling European and American hardwoods. The yields from the Baroda woods were, as a rule, lower than those from the corresponding Mysore woods. Undried coconut shells yielded 4·90—6·90% of acetic acid and 0·66—1·54% of methyl alcohol; wattle wood (*Acacia decurrens*), the bark of which is utilised for the extraction of tannin, gave yields which compared favourably with those obtained from hardwoods; myrobalan kernels, the husks from the dry pods of the gold mohur tree (*Poinciana regia*), and bamboo gave yields comparable with those from the South Indian jungle woods.—L. A. C.

Tar from coconut shells. Sudborough and others. *See* III.

Patents.

Vertical retorts for the destructive distillation of coal, shale and the like. S. Jones and J. D. Macdonald. E.P. 109,800, 23.8.17. Conv., 15.7.16.

Near the bottom of the retort and external to it is a special valve consisting of two smooth plates with a drum in between. The drum has two pockets, one on each side of the centre, and each plate has an opening opposite to the position of one pocket, such opening in one plate being placed opposite the neck of the feed hopper, whilst the opening in the other plate affords communication between the second pocket in the drum and a short conduit leading into the bottom of the retort. By rotating the valve drum through 180° the material supplied to one pocket from the hopper is caused to pass through the valve into a conduit from which it is forced to the top of the retort by means of an archimedean screw. The hood of the retort forms the gas and coke exit and is water-sealed, the coke being removed along a channel by push-plate conveyors. —A. G.

Carbonaceous material; Apparatus for distilling ——. W P. Perry. E.P. 158,394, 10.11.19.

An apparatus for continuously distilling and gasifying carbonaceous material comprises a distilling chamber having feed appliances at the top and apparatus for ash removal at the bottom. The chamber has a number of openings in the walls, or louvres on two opposite sides, a chamber on one side opening into the distilling chamber at the lower part for distributing hot gases into the mass through the openings, and a chamber on the other side for receiving the gases and vapours through the openings from the distilling chamber. Outlets are provided from the collecting chamber for conducting away the gases, vapours, and liquid distillates.—A. G.

Carbonisation of coal, lignite, shale, and like materials; Apparatus for ——. G. F. Bale. E.P. 158,622, 4.11.19.

The retort comprises an inner and an outer vertical shaft, separated by a heating space. The central shaft is surmounted by an annular cast-iron trunk which serves to collect distillate and to prevent it from returning by gravity to the inner

shaft. A sliding box is operated by a ram under the central chamber, so that a predetermined quantity of carbonised material can be removed from the retort at any time.—A. G.

Carbon; Process of activating ——. J. C. Woodruff. U.S.P. 1,368,987, 15.2.21. Appl., 8.5.19.

CARBON is activated by oxidation by continuously agitating it whilst conveying it through a reaction zone, wherein it is subjected to the combined action of steam and hot combustion gases.—A. B. S.

Incandescence gas mantles; Manufacture of ——. W. Marshall. E.P. 158,779, 19.12.19.

CELLULOSE acetate employed in the manufacture of incandescence gas mantles is subjected to a process of partial or complete de-acetylation by treating the material or the mantle with solutions of the hydroxides, carbonates, or silicates of sodium or potassium, or a mixture thereof, at a temperature below 212° F. (100° C.) for 10—30 mins. The mantle or material is then impregnated with thorium and cerium nitrates in the usual manner. —J. S. G. T.

Electric arc lamps or projectors and carbons or electrodes therefor. C. B. Burdon. From Siemens-Schuckertwerke, G.m.b.H. E.P. 158,380, 6.11.19.

AN anode for use in a high-effect projector is composed of a carbon tube having a wick or core containing cerium or a non-pyrophoric alloy thereof, mixed in a finely divided state with pulverised carbon or graphite, and a binding medium such as tar. The external diameter of the anode is smaller than the normal crater diameter of a pure carbon anode for the same load.—J. S. G. T.

III.—TAR AND TAR PRODUCTS.

Tar from coconut shells. Wood distillation. IV. J. J. Sudborough, H. E. Watson, and M. K. Narasimhan. J. Indian Inst. Sci., 1920, 3, 293—306.

THE tar from coconut shells yielded on distillation about 24% of aqueous distillate with 8% of acetic acid and 44% of oils volatile below 260° C. which gave 30% of phenolic substances soluble in sodium hydroxide solution. These substances on fractionation yielded 6·2% of phenol and 5·86% of creosote, b.p. 200°—230° C., containing 0·43% of guaiacol, the yields all being calculated on the weight of the tar. The sp. gr. of the creosote, however, was lower than that required by either the British or U.S. Pharmacopœia.—L. A. C.

Tar-oils; Determination of acids in ——. A. Lazar. Chem.-Zeit., 1921, 45, 197—199.

FOR the estimation of creosote (tar acids), especially in low-temperature tar oils, a gravimetric method is recommended. The oil is treated with 5% sodium hydroxide, the alkaline creosote solution decomposed with dilute sulphuric acid, and the creosote extracted with ether. The ethereal solution is first distilled, after which the last traces of ether are removed by careful heating over a small flame. In the differential method, in which the oil is treated with sodium hydroxide, and the increase in volume of the latter is measured, addition of benzene to prevent solution of substances other than creosote may result in absorption of part of the benzene itself. The benzene should first be added to the sodium hydroxide, and the oil then introduced. After reading the volume the alkaline creosote solution is distilled, and a correction is made for the benzene which is recovered from it. —W. J. W.

Phenol; Characteristic reaction of ——. G. Rodillon. J. Pharm. Chim., 1921, 23, 136—137.

TEN c.c. of a solution containing phenol is treated with a drop of 10% sodium nitrite solution and the mixture is poured on the surface of concentrated sulphuric acid. A coloured zone develops at the point of contact of the two liquids, the upper part of the zone being red and the lower green. —W. P. S.

Phenol and some mineral solutions; Miscibility of ——. *Analytical applications.* R. Dubrisay. Bull. Soc. Chim., 1921, 29, 78—88.

A DETAILED account of work already published (*cf.* J., 1919, 37 A, 103 A; 1920, 542 A, 766 A).—W. G.

Sulphonation of anthraquinone; Catalytic action of mercury in the ——. A. Roux and J. Martinet. Comptes rend., 1921, 172, 385—387.

IN the absence of mercury the sulphonation of anthraquinone yields the β-sulphonic acid, but in the presence of mercury at a lower temperature the product is the α-acid. It is shown that in both cases the first product is the α-acid, but that at the higher temperature required in the absence of mercury the velocity of transformation of the α-acid into the β-acid is as great as the velocity of sulphonation. In the presence of mercury, but at the higher temperature, the product is also the β-acid, and a higher yield is obtained.—W. G.

Phenanthrene; Bromine compounds of ——. H. Henstock. Chem. Soc. Trans., 1921, 119, 55—61.

THE bromination of phenanthrene in carbon tetrachloride solution using four atoms of bromine for 1 mol. of phenanthrene gave 31% of 9-bromophenanthrene and 30% of 2(?)-bromophenanthrene dibromide, which decomposed at 100° C. to hydrogen bromide and 2(?) 10-dibromophenanthrene. The position of the 10-bromine atom was demonstrated by the oxidation of the compound to a dibromophenanthrone, instead of to a quinone which would have been formed were the 10-position unoccupied. The position of the second bromine atom is uncertain, the only evidence being that 2-ethoxyphenanthrene similarly treated gave only a 10-monobromo-substitution product.—G. F. M.

Carbazole; Oxidation of ——. W. H. Perkin, jun., and S. H. Tucker. Chem. Soc. Trans., 1921, 119, 216—225.

BY the action of potassium permanganate on carbazole in boiling acetone solution three substances are produced, viz., two crystalline compounds, melting at 220°—221° C. and 265° C. respectively, and an amorphous substance. The crystalline compounds are isomeric dicarbazyls having the molecular formula $C_{24}H_{16}N_2$. All three substances can be nitrated and brominated and react under certain conditions with acetic anhydride. They differ from carbazole in that they do not form picrates. —G. F. M.

Tetrahydronaphthalene derivatives from γ-phenyl-fatty acids. Kon and Stevenson. *See* XX.

PATENTS.

Coal tar; Process of treating ——. W. Anderson and J. Meikle. E.P. 158,337, 31.10.19.

THE tar is preheated and injected by means of superheated steam in excess of that required to vaporise the tar into a length of tubing, *e.g.*, 72 ft. of 5 ins. diam., at such a rate that 20 tons of tar is distilled in 24 hrs. The products pass into a chamber wherein carbon is deposited, and thence into a series of condensers for fractional condensation of the products of the reaction, which consist of gas, carbon, a liquid similar in appearance to coal

tar creosote, and a reddish-brown solid of resinous appearance, of which about 40% is soluble in alkalis and about 9% in acids.—L. A. C.

Still [for distillation of pitch]. H. P. Hird. U.S.P. 1,368,149, 8.2.21. Appl., 27.6.19.

THE still has a circular cross-section and a curved longitudinal axis, the ends of the still being turned upwards so as to be above the normal level of the pitch. Openings with removable lids are provided at each end for removing the residue from the still, and an inlet is attached to one end and a vapour outlet to the other.—L. A. C.

Naphthalene and its derivatives; Manufacture of condensation products of —— with aralkyl halides. Farbenfabr. vorm. F. Bayer und Co. G.P. 301,713, 29.1.16.

THE condensation is carried out in presence of small amounts of iron or its compounds. By the condensation of methylnaphthalene with benzyl chloride an odourless oil is formed, soluble in benzene and petroleum spirit, whilst naphthalene and xylyl chloride yield an odourless, yellowish-red oil, b.p. 220°—380° C. at 25 mm. The products may be used for technical and medicinal purposes, *e.g.*, for skin diseases as substitutes for tar.—C. A. C.

Converting hydrocarbons. E.P. 135,197. *See* IIA.

IV.—COLOURING MATTERS AND DYES.

Indigoid dyestuffs; Colour of ——. J. Martinet. Rev. Gén. Mat. Col., 1921, 25, 17—18.

FACTS such as the increase in the depth of colour in passing from brown-red isoindigo to violet-red indirubin and blue indigo, the existence of a similar relationship in the case of oxindigo, thioindigo, and indigo, and the diminution in the depth of colour produced by substituents, such as methyl, hydroxyl, and amino groups and the halogens in the 6.6′ positions, could be predicted by the application of the following rules. The union of an auxochrome and a chromophor by means of a chain of conjugated double bonds between carbon atoms leads to an increase in the depth of colour (bathochromic effect). The direct union of a chromophor and an auxochrome decreases the depth of colour (hypsochromic effect). In the case of isoindigo the auxochrome NH groups are directly attached to the chromophor CO groups and are consequently in an unfavourable position for the production of colour, whereas in indigo the NH group exerts its maximum effect because it is attached to the CO group by a benzene nucleus on one side and by a carbon atom, which forms part of a chain with double conjugated bonds, on the other. The formula of indirubin is intermediate between the two, and this fact is reflected in its colour. The increase in the depth of colour in passing from oxindigo to thioindigo and indigo is a bathochromic effect due to the increasing power of the auxochromes C_6H_5O, C_6H_5S, C_6H_5NH, and is in agreement with experience in other series. The effect of two auxochromes is cumulative when in the *p*-position, but they act in contrary directions when in the *m*-position with respect to one another. This also is in agreement with experience in other series, but is particularly well exemplified in the indigoid series, for all 5.5′-derivatives are deeper in colour than the corresponding 6.6′-derivatives. (*Cf.* J.C.S., April.)—F. M. R.

o-Chlorodinitrotoluenes. II. G. T. Morgan and L. A. Jones. Chem. Soc. Trans., 1921, 119, 187—192.

2-CHLORO-4.6-DINITROTOLUENE, recently isolated from the nitration product of 2-chloro-4-nitrotoluene (J., 1920, 623 A), has now been obtained to a similar extent in the nitration of 2-chloro-6-nitrotoluene. 6-Chloro-2.4-tolylenediamine, which it yields on reduction with alcoholic stannous chloride, yields azo- and bisazo-derivatives of the chrysoidine series resembling those obtained from 6-chloro-3.5-tolylenediamine (Chem. Soc. Trans., 1902, 81, 97). The action of ammonia and primary amines, such as methylamine or aniline, on 2-chloro-4.5-dinitrotoluene leads to the displacement of the 5-nitro-group by the aminic radicle, whilst in the case of 2-chloro-5.6-dinitrotoluene it is the 6-nitro group which is displaced.—G. F. M.

Catechin; Constitution of ——. III. Synthesis of acacatechin. M. Nierenstein. Chem. Soc. Trans., 1921, 119, 164—170.

IN a previous communication (*cf.* J., 1920, 685 A, 777 A) it was provisionally suggested that catechin is 2.4.6.3′.4′-pentahydroxy-3-phenylchroman. This substance has now been synthesised from 3.4.2′.4′.6′-pentamethoxydiphenylmethyl chloromethyl ketone, which was converted by the action of aluminium chloride into 4.6.3′.4′-tetramethoxy-3-phenylchroman-2-one. This was reduced to the corresponding hydroxy-compound, which proved to be identical with acacatechin tetramethyl ether, and on demethylation it gave the above-mentioned pentahydroxyphenylchroman, identical in all respects with acacatechin.—G. F. M.

PATENTS.

Dye substitute. A. L. Clapp, Assr. to The Metalite Co. U.S.P. 1,367,862, 8.2.21. Appl., 20.12.15.

THE product obtained by dissolving leather in a hot aqueous solution of caustic soda (proportions: 100 lb. of leather, 15 lb. of caustic soda, and 1000 qts. of water) may be used for dyeing fabrics, pulp products, paper, leather, and similar substances. —C. A. C.

Dye. S. M. Tootal. U.S.P. 1,367,930, 8.2.21. Appl., 22.4.20.

A PREPARATION for dyeing silk or wool in mixed fabrics whilst leaving the cotton unaffected is composed of a weakly acid dyestuff, a gelatinous substance, and a weak organic acid.—C. A. C.

Indigo and other vat dyestuffs; Process for obtaining —— in a finely divided form. C. H. Boehringer Sohn. G.P. 326,573, 9.10.17.

THE separation of the dyestuff from solutions of indigo white or analogous compounds of other vat dyes, is carried out in presence of salts of bile acids. On blowing air through a solution of sodium-indoxyl containing 5—10% of sodium cholate, indigo separates in a very fine form, particularly suitable for vat working.—J. H. L.

Lake colours. U.S.P. 1,358,007. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Wool fabrics; Formation of stains on, and tendering of —— due to faulty carbonisation. P. Heermann. Textilber., 1921, 2, 106—107.

LARGE and small dark stains often found in coloured woollen dress materials which have been carbonised are due to the use of too strong an acid or too high a temperature during carbonisation. Where the material is stained, the wool is tender and under the microscope is shown to be completely destroyed. —A. J. H.

Cellulose; Methylation of ——. *III. Homogeneity of product and limit of methylation.* W. S. Denham. Chem. Soc. Trans., 1921, **119**, 77—81. (*Cf.* J., 1913, 974; 1914, 1084.)

HIGHLY methylated celluloses were obtained by treating cotton with sodium hydroxide solution and then with methyl sulphate, and repetitions of this process, variously modified, have yielded a product containing 44·6% of methoxyl, a value approximating to that theoretically required for trimethylcellulose. This is regarded as the limit of methylation and as far as could be ascertained from its behaviour to Schweitzer's reagent, in which it was quite insoluble whilst lower methylated celluloses were partially soluble, it was apparently homogeneous.—G. F. M.

Nitrocellulose solutions. Herzog and others. *See* XIII.

Pyroxylin compositions. Lorenz. *See* XV.

Cellobiose. Haworth and Hirst. *See* XVII.

PATENTS.

Balloon or like fabrics. C. A. Cleghorn. E.P. 158,366, 4.11.19.

FABRIC prepared with bird-lime according to E.P. 142,160 (J., 1920, 444 A) does not adhere well to a non-absorbent fabric. To avoid this difficulty, fabric is coated with a thin layer of Turkish bird-lime (E.P. 130,379; J., 1919, 730 A), heated to 180° F. (82° C.) to expel moisture, coated with a rubber solution, and placed in contact with a second sheet of fabric. For preparing single fabrics the rubber is dried and vulcanised, or coated with shellac varnish, or replaced by shellac varnish; 0·1% of mercuric chloride incorporated with the bird-lime is a suitable preservative. —A. J. H.

Retting flax or the like; Process of ——. B. S. Summers. E.P. 158,807, 1.5.20.

FLAX is retted in open tanks by the usual process, except that the retting liquor is continuously withdrawn, filtered, diluted so that its oxygen absorption value, as measured by means of a standard solution of potassium permanganate, is maintained constant, and returned to the retting tanks. By this means the increase of harmful putrefying bacteria is checked.—A. J. H.

Fabrics and packings, such as bags; Process of protecting —— *against chemical corrosive action.* A Bruno. U.S.P. 1,367,177, 1.2.21. Appl., 21.11.18.

FINELY-GROUND chalk and a colloidal agglutinant diluted with water are applied to fibres to be used for fabrics, *e.g.*, bags, to contain corrosive materials.—A. de W.

Fibres of the agave and similar fleshy plants; Method of liberating the ——. R. Quijano. U.S.P. 1,368,750, 15.2.21. Appl., 4.8.19.

THE fibres are separated by crushing the cut plants, soaking the leaves in a bath capable of removing the easily soluble gums, washing, and boiling with a reagent capable of removing the remaining gums. —A. J. H.

Fibrous plants, such as the stinging nettle and the like; Pre-treatment of woody —— *for the dry breaking process.* Nessel-Anbau-Ges.m.b.H., and A. Hoermann. G.P. 326,489, 17.9.18.

BEFORE being dried the plants are impregnated with substances which inhibit the action or development of bacteria, *e.g.*, antiseptics, per-salts, and diastatic enzymes, especially diastatic malt preparations.—J. H. L.

Textile fibres; Preparation and improvement of ——. E. Herzinger. G.P. 328,595, 21.1.19.

THE material is treated with alkali sulphide solution, squeezed, and without being rinsed is introduced into an acid bath.—J. H. L.

Fibrous plants; Process for the simultaneous production of textile fibres and paper pulp from ——. Nessel-Anbau-Ges.m.b.H. G.P. 328,596, 2.2.18.

THE plant material is treated with suitable reagents under pressure or in concentrated form, in presence of dissolved or emulsified vegetable, animal, or mineral oils or fats, or halogen derivatives of hydrocarbons, which serve to protect the bast fibres. After the treatment the material is rinsed with water or suitable solutions, and neutralised if necessary with acids or acid salts; the bast fibres are separated from the cellulose fibres derived from the woody tissue, and the latter can be used for the manufacture of paper.—J. H. L.

Straw and similar materials; Production of textile fibres from ——. G. Strauss. G.P. 328,597, 5.2.20. Addn. to 323,669 (J., 1920, 744 A).

HYDROGEN peroxide is added to the steeping solution.—J. H. L.

Wool, woollen yarn, and woollen fabrics; Process for the removal of fat from raw ——. S. Aschkenasi. G.P. 329,008, 1.6.16.

THE soap solutions commonly employed for the purpose are neutralised or acidified with lipolytic substances, viz., hydroricinoleic acid, naphthalenesulphonic acid, Twitchell's reagent, contact hydrolysts, or sulphonated fats. The injurious action of alkali on the wool is thus avoided, and the fatty acids remain dissolved.—J. H. L.

Material for bandages and filter cloths; Manufacture of adsorptive and absorptive ——. R. Marcus. G.P. 329,310, 8.10.15.

TEXTILE material is soaked in a colloidal solution of silicic acid and then dried. Other soluble substances, as silver, iron, and other salts, may be applied together with the silicic acid.—C. A. C.

Fabrics; Composition for removing iron rust from ——. J. E. Gliott. U.S.P. 1,368,714, 15.2.21. Appl., 8.2.19.

IRON rust is removed from fabrics by treatment with a solution of hydrofluoric acid mixed with an amount of borax in excess of the chemical equivalent.—A. J. H.

Acetylcellulose; Process for preparing layers of —— *for coating materials.* A. Eichengrün, Assr. to American Cellone Co. U.S.P. 1,357,447, 2.11.20. Appl., 11.4.10. Renewed 2.4.20.

A SOLUTION is prepared by treating cellulose acetate in the cold with two solvents of which, when used alone, one is capable of dissolving cellulose acetate in the cold but the other only on heating.

Viscose; Process for producing threads from ——. C. A. Huttinger and E. Rittenhouse, Assrs. to The Acme Woolen-Cotton Mills Co. U.S.P. 1,367,603, 8.2.21. Appl., 3.12.19.

VISCOSE is forced in multiple streams into a precipitating bath containing an aqueous solution of sodium bisulphate and molasses, and the resulting filaments are spun, whereby a soft and open thread is obtained.—A. J. H.

Cellulose and artificial resin, lacquer, etc.; Treatment of wood or cellulosic materials for the production of ——. R. Hartmuth. G.P. 328,783, 27.11.19. Addn. to 326,705 (J., 1921, 144 A).

INORGANIC or organic acids, or acid substances, with the exception of hydrochloric acid, may be employed as catalysts. The following catalysts for the phenolic digestion process are mentioned:—ammonium salts, stannous, stannic, aluminium, and zinc chlorides, silicon tetrachloride, and nitro- and chloro-phenols.—J. H. L.

Cellulose; Production of ——. Köln-Rottweil-A.-G. G.P. 329,566, 16.1.20.

WOOD and other cellulosic substances are treated at high temperatures with glycol or mineral acid esters of polyhydric alcohols, *e.g.*, dichlorohydrin, with or without the aid of high pressures, or catalysts, such as sulphuric or hydrochloric acid or zinc chloride. The esters also accelerate the action of polyhydric alcohols when used with the latter, and they facilitate the solution of encrusting substances in acetone, acetic acid, etc.—J. H. L.

Wood-like article of manufacture and process of making the same. T. B. Mobler and O. Ludekens, Assrs. to The Moludite Co. U.S.P. 1,357,647, 2.11.20. Appl., 22.9.19.

CRUSHED barley is boiled with water, then fermented with yeast, the product treated with a small quantity of precipitated iron carbonate and mixed with paper or with the pulp obtained by digesting straw or the like with alkali, so as to obtain a plastic dough, which is moulded and baked.

Paper yarn and fabrics and other cellulose threads; Process for obtaining —— of wool-like character. E. Herzinger. G.P. 326,806, 21.1.19.

THE material is treated with solutions of alkali sulphides, whereby it is rendered soft and wool-like to the touch and partially bleached. On pressing it becomes compact like a true textile fabric, and remains soft.—J. H. L.

Waste paper; Apparatus for (A) *decolorising,* (B) *decolorising and disintegrating* ——. W. Abele. G.P. (A) 328,671, 17.8.19, and (B) 328,731, 8.1.20. Addns. to 305,343 (J., 1918, 410 A).

(A) THE heater is situated within the decolorising vessel. (B) The liquid is circulated through the material by means of a steam injector pump mounted outside the vessel.—J. H. L.

Paper and other cellulose products; Production of absorbent ——. Zentralstelle für wiss.-techn. Untersuchungen G.m.b.H. G.P. 328,788, 27.11.19.

THE pulp, before or after it has been given its final shape, is dried in a frozen state. The fibres are thus prevented from adhering together, and the products possess great absorbent capacity.
—J. H. L.

Cork; Production of shaped pieces of —— of low specific gravity, by heating cork fragments in moulds. Grünzweig und Hartmann, G.m.b.H. G.P. 326,882, 7.5.13.

THE material is heated between 250° and 300° C. by placing the mould in a heating space which, throughout the whole heating process or during the latter part, has a constant maximum temperature of 360° C. Moulded forms having density as low as 0·05 may be produced.—J. H. L.

Wool substitute from cellulose solutions; Process for manufacturing a ——. Glanzfäden A.-G. E.P. 135,206, 13.11.19. Conv., 14.7.17.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Aniline Black dyeing. J. Schmidt. Textilber., 1921, 2, 105—106.

THE loss of strength of fabrics dyed with Aniline Black under the most favourable conditions is 5—15%. When "aniline salt" is used in the padding liquor, the free mineral acid which it contains is neutralised with aniline oil, and acetic, formic, or lactic acid is added; 30 pts. of sodium chlorate is required to oxidise 100 pts. of aniline salt. Attempts to replace sodium chlorate by perborates or peroxides were unsuccessful because the resulting mixtures were unstable. Copper salts used as catalysts help to tender the fabric. The strength of the fabric is unaffected by the addition of 1—2% of acetic, formic, or lactic acid to the padding liquor, but tartaric acid produces tendering. The presence of alkaline-earth salts of acetic and formic acids in the padding liquor preserves the fabric, since a metallic hydroxide is formed within the fibres. Magnesium chloride (30 c.c. of a 6% solution per 1000 c.c. of padding liquor) is a suitable hygroscopic substance. The ageing-chamber should be well ventilated so as to remove acid vapours; the temperature should not exceed 30°—35° R. (38°—44° C.) and the atmosphere contained therein should be 50% saturated with moisture. After chroming, the fabric should be soured, washed twice, and soaped.—A. J. H.

Sodium sulphide in sulphide dye-baths; Determination of ——. W. Herbig. Z. angew. Chem., 1921, 34, 89—92.

THE results obtained in the estimation of pure sodium sulphide with zinc sulphate and sodium nitroprusside agree well with those obtained by titration with iodine. The former method also gives approximately concordant results with those of control experiments in the case of the estimation of the residual sodium sulphide in used dye-baths, but with freshly prepared sulphide dye solutions the zinc sulphate method gives very irregular results. In the preparation of the sulphide dye solution, owing to the interaction of the dye with sodium sulphide, as much as 50—80% of the latter is consumed in certain cases. It would appear that the addition of soda in the preparation of sulphide dye solutions has only a slight influence on this consumption of sodium sulphide; nevertheless, it is recommended that sulphide dyes should be worked into a paste with soda, prior to the addition of sodium sulphide.—F. M. R.

PATENTS.

Fibres, threads or fabrics [of cellulose acetate]; Dyeing or colouring ——. British Cellulose and Chemical Manuf. Co., J. F. Briggs, and C. W. Palmer. E.P. 158,340, 31.10.19.

AFTER treatment with a solution of ammonium thiocyanate, cellulose acetate has an increased affinity for all classes of dyestuffs. Fabrics containing cellulose acetate are immersed for 2—60 mins. at ordinary temperature in a 5—25% solution of ammonium thiocyanate, thoroughly washed, and dyed in the usual manner. In some cases, the ammonium thiocyanate may be added to the dye-bath. Sodium, potassium, and calcium thiocyanates may also be used.—A. J. H.

Dyeing; Process of ——. H. B. Smith, Assr. to Surpass Chemical Co. U.S.P. 1,368,298, 15.2.21. Appl., 30.1.20.

COTTON material is treated in a dye bath to which is subsequently added an alkaline oxidising agent so as to remove the motes, shives, and/or leaf which the material contains.—A. J. H.

Patterns resembling marble or battick effects; Production of ——. C. Jäger, G.m.b.H., and R. W. Carl. G.P. 329,173, 14.5.19.

A SOLUTION of a dye soluble in oil or fat is suitably disposed on the surface of water or other liquid and the material to be coloured is laid thereon and then removed and dried.—J. H. L.

Overprinting fabrics and yarns [; Machines for ——]. Calico Printers Assoc., Ltd., F. and R. Ashton, and G. Mellor. E.P. 158,407, 14.11.19.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Lead sulphuric acid chamber; Methods of introducing nitrogen compounds into the ——. G. Gianoli. Giorn. Chim. Ind. Appl., 1921, 3, 11—12.

THE author discusses the advantages and disadvantages attaching to each of the different methods which have been suggested for supplying the nitrous compounds required in the manufacture of sulphuric acid, with special reference to the investigations of Lemaitre (J., 1920, 655 A) and to his own proposal to employ in the Glover tower a mixture of sulphuric and nitric acids obtained by pouring sulphuric acid of 20° B. (sp. gr. 1·16) into concentrated sodium nitrate solution and removing the sodium bisulphate, which crystallises out on cooling (Sixth International Congress of Applied Chemistry, 1906). —T. H. P.

Nitrogen; Fixation of atmospheric —— *by the silent electric discharge process. I.* C. F. Harding and K. B. McEachron. Amer. Inst. Elect. Eng., 9.4.20. [Advance copy.]

THE results of experiments on the production of nitric acid by the passage of a silent electric discharge through fixed volumes of air or other nitrogen-oxygen mixtures were recorded by Spiel in a paper not generally accessible (Thesis, Vienna Technical High School, 1909). Spiel found that during the discharge the pressure gradually fell to a minimum, and subsequently a reversal of the reaction took place, the pressure gradually returning to the initial or even a greater value. At the reversal point the concentration of nitric oxide was about 5 to 6% by vol., but at the final equilibrium it was only about 0·6%. Experiments have now been made in which a continuous current of dry air was passed through an apparatus in which it was subjected to the silent discharge. In the large scale apparatus used the discharge took place inside an aluminium tube 5 ft. long and 6 in. diam. In the axis of the tube was supported an aluminium rod ⅝ in. diam., and between this and the aluminium tube was a porcelain tube which served both as a high dielectric and to divide the space into two compartments. The air current passed first in one direction between the aluminium and porcelain tubes and then in the other between the porcelain tube and the rod. By means of a pump air could be passed through the apparatus at pressures above or below atmospheric. Trial runs were made at pressures of 460, 560, 660, 710, and 780 mm. at room temperature. At each pressure the production of nitric acid increased rapidly as the rate of passage of air increased, the maximum being attained at a rate of about 6 l. per min.; with greater velocities the yield diminished. With constant air velocity the yield increased rapidly with increasing pressure. The highest yield obtained was 9·8 g. HNO_3 per k.w.-hr. at 780 mm. and 6 l. per min., and the limit has certainly not been approached. At higher velocities the absorption of nitric acid was probably imperfect. In an analysis of the heat losses and energy consumed in producing nitric acid 25·8 watt-hours out of 134 are unaccounted for. On theoretical grounds, if all the electrical energy were available for the reaction, the yield would be 250 g. HNO_3 per k.w.-hr., whilst the arc process at 4200° C. can only be expected to give 134 g. per k.w.-hr. At equal efficiencies, therefore, the silent discharge process should give a higher yield and should be much cheaper.—E. H. R.

Nitrogen pentoxide; Thermal decomposition of gaseous ——. F. Daniels and E. H. Johnston. J. Amer. Chem. Soc., 1921, 43, 53—71.

THE thermal decomposition of nitrogen pentoxide is a unimolecular reaction at all temperatures from 0° C. to 65° C. The reaction has a large temperature coefficient, viz., 200—300% for 10°, and is not catalysed by the glass walls of the decomposition vessel. (*Cf.* J.C.S., April.)—J. F. S.

Nitrogen pentoxide; Photochemical decomposition of ——. F. Daniels and E. H. Johnston. J. Amer. Chem. Soc., 1921, 43, 72—81.

NITROGEN pentoxide is decomposed by light of wave length 400—460 $\mu\mu$ if nitrogen dioxide is present. The autocatalytic effect of the dioxide is negligible in the dark. (*Cf.* J.C.S., April.)—J. F. S.

Ammonia; Actual state of the synthesis of —— at extremely high pressures. G. Claude. Comptes rend., 1921, 172, 442—444.

In the latest development of the synthesis of ammonia at extremely high pressures (*cf.* J., 1919, 885 A; 1920, 61 A, 187 A, 655 A, 746 A) the compression of the reacting gases from 100 atm. to 900 atm. is effected in one stage in a hyper-compressor capable of dealing with 700 cb. m. of the gases per hr., a quantity sufficient for an apparatus with a capacity of 5 tons of ammonia per day. The contact unit now used comprises four tubes, two in parallel and then two in series. The heat of the reaction is carried away from the contact unit by a stream of molten lead.—W. G.

Carbon monoxide; Absorption of —— by cuprous ammonium carbonate solutions. W. R. Hainsworth and E. Y. Titus. J. Amer. Chem. Soc., 1921, 43, 1—11.

For the removal of the last portions of carbon monoxide from gas mixtures used in synthetic ammonia processes (after removing the major portion by oxidation to carbon dioxide and absorption of the latter in water), ammoniacal cuprous chloride solutions are unsatisfactory owing to the tendency to deposit copper and to gradual solution of the iron walls of the containing vessel. These tendencies are greatly reduced if an ammoniacal cuprous salt of an organic acid, *e.g.*, the formate or carbonate, is used instead of the chloride. The absorption capacity of a solution of cuprous ammonium carbonate for carbon monoxide is dependent on the concentration of cuprous copper, the partial pressure of the carbon monoxide, and the concentration of free ammonia. Absorption is due to the formation of an unstable compound, $Cu_2(NH_3)_{2n}CO_3,2CO,4H_2O$. The presence of small quantities of oxygen prevents the reduction of the cuprous copper to metallic copper and increases the absorption capacity of the solution. The solution of cuprous ammonium carbonate may be regenerated after use by heating to 75° C. in an inert atmosphere at ordinary pressure. (*Cf.* J. C. S., April.) —J. F. S.

Trithiocarbonates and perthiocarbonates. E. W. Yeoman. Chem. Soc. Trans., 1921, 119, 38—54.

Two well-defined series of thiocarbonates, derived respectively from trithiocarbonic acid, H_2CS_3, and perthiocarbonic acid, H_2CS_4, have been prepared, the methods adopted in general being the addition of the theoretical quantity of carbon bisulphide to an alcoholic or aqueous solution of the metallic hydrosulphide for the trithiocarbonates, or to a solution of the disulphide of the metal for the perthiocarbonates. From the hot alcoholic or aqueous solutions the salts were deposited in crystalline form on cooling or on addition of ether. The trithiocarbonates of sodium, potassium, ammonium, barium, strontium, and magnesium form yellow or red crystals, soluble in water, giving yellowish-red solutions. They are stable in dry air free from carbon dioxide, but are very hygroscopic, particularly the alkali trithiocarbonates, and if allowed to become moist they quickly oxidise and decompose with loss of carbon bisulphide. Aqueous solutions of the trithiocarbonates dissolve and combine with an additional atom of sulphur with formation of the perthiocarbonates, which are, however, more readily obtained by the alternative method above. The perthiocarbonates of the alkali and alkaline-earth metals are yellow, deliquescent, crystalline solids, soluble in water giving yellow solutions, from which mineral acids precipitate perthiocarbonic acid as a red oil. The calcium thiocarbonates all appear to be basic salts, which are more stable than the normal salts, and less hygroscopic.—G. F. M.

Manganese salts; Reaction of ——. V. Macri. Ann. Chim. Analyt., 1921, 3, 55—56.

The author claims priority (J., 1917, 1176) for the oxalate reaction of manganese salts described by Caron and Raquet (J., 1919, 574 A).—W. P. S.

Salts; Double decompositions of —— and their geometric representation. H. Le Chatelier. Comptes rend., 1921, 172, 345—350.

A graphical method for the investigation of systems composed of mixtures of salts is described. The method is illustrated by reference to the double decomposition, $NaNO_3+NH_4Cl=NaCl+NH_4NO_3$, and a diagram is figured and described which facilitates the solution of the following problems:—The determination of the composition of mixtures of three salts; the determination of the surface of saturation; control of the progress of crystallisation and determination of the quantity of salt deposited; determination of the conditions under which there is re-solution of one of the salts at the invariant point.—W. G.

Saline solutions; Displacement of metals in ——. Barlot. Comptes rend., 1921, 172, 378—381.

The precipitation of one metal from a solution of one of its salts by a more electronegative metal may most readily be followed by soaking a filter paper in a solution of the salt, placing it on a glass plate, and then placing a fragment of the more electronegative metal on the paper. (*Cf.* J.C.S., April.) —W. G.

Fractional precipitation [of copper and silver and of cobalt and nickel]. P. Jolibois, R. Bossuet, and Chevry. Comptes rend., 1921, 172, 373—375.

Using the method previously described (J., 1920, 84 A, 107 A), it was found that on adding increasing quantities of sodium hydroxide solution to a solution of copper and silver nitrates the fractionation is perfect, no silver appearing in the precipitate until sufficient sodium hydroxide has been added to precipitate the whole of the copper. On adding sodium hydroxide to a solution of nickel and cobalt chlorides the fractionation is imperfect, both metals always appearing in the precipitate, although in the early stages the nickel predominates.—W. G.

Magnesium carbonate; Crystalline ——. T. C. N. Broeksmit. Pharm. Weekblad, 1921, 58, 210—212.

The amorphous precipitate obtained by adding sodium, potassium, or ammonium carbonate to magnesium sulphate solution becomes crystalline on standing. No double salt is formed. Exactly similar crystals are obtained with calcium salts. —S. I. L.

Silicic acid gels. R. Schwarz. Kolloid-Zeits., 1921, 28, 77—81.

Silicic acid gels dissolve in ammonia to form both a colloidal solution and a molecular disperse solution, that is ammonium silicate. On keeping such a solution the amount of ammonium silicate increases at the expense of the colloidal silicic acid.—J. F. S.

Colloids; Rôle of protective —— in catalysis [of hydrogen peroxide by colloidal platinum]. T. Iredale. Chem. Soc. Trans., 1921, 119, 109—115.

The inhibitive effect of protective colloids on the catalytic decomposition of hydrogen peroxide by colloidal platinum decreases in the order: gelatin, egg albumin, tragacanth, dextrin, gum arabic. With a strong protective colloid, such as gelatin, the inhibitive effect is noticeable at a dilution as great as 0·000005%. The inhibition is explained on the ground of selective adsorption resulting in a decreased concentration of hydrogen peroxide at the platinum surface and a consequent fall in the

value of the velocity constant. The reaction may be used to detect not only adsorption effects, but probably also changes in state of the protective colloid, as the most striking fact about the results with varying concentrations of gelatin, for example, was the gradual rise of the velocity constant with diminishing concentration down to 0·00005%, and the rapid rise on further dilution, which seemed to indicate that the initial dilution caused the larger gelatin ultramicrons to split into smaller ones down to a certain limit, thus compensating for the decreased concentration, after which further dilution of the colloid caused a rapid rise in the velocity constant.—G. F. M.

Ruthenium and osmium; Action of hydrochloric acid on the tetroxides of ——. H. Remy. J. prakt. Chem., 1920, **101**, 341—352.

THE contradiction between the statements that concentrated hydrochloric acid reacts with osmium tetroxide at the ordinary temperature, and that no action occurs (J., 1919, 133 A), is shown to be due to differences in strength of acid employed. Acid of sp. gr. >1·160 reacts at the ordinary temperature, giving osmium tetrachloride; the same acid with ruthenium tetroxide reacts still more readily, forming the trichloride.—J. K.

Cyanogen chloride; Preparation and some physical constants of ——. C. Mauguin and L. J. Simon. Ann. Chim., 1921, **15**, 18—41.

AFTER an examination of different methods for the preparation of cyanogen chloride, the authors find that the best yield is obtained by the action of chlorine on hydrocyanic acid (*cf.* Price and Green, J., 1920, 98 T). For the pure chloride the b.p. is 12·5° C. at 755 mm.; m.p., −7° to −6° C.; D, 1·222; mean coefficient of expansion between 0° and 45° C., 0·0015.—W. G.

Iodine; Action of —— *in the cold on different metals. Process for detecting the presence of chlorine in the atmosphere.* C. Matignon. Comptes rend., 1921, **172**, 532—534.

IODINE placed on thin sheets of metals such as silver, copper, aluminium, tin, or zinc gradually converts the whole of the metal into the iodide. The action spreads outwards from the point of contact, the velocity varying with the metal. For the detection of chlorine in the air, a thin sheet of beaten silver, 1 cm. in diameter, covered with moist potassium iodide and forming part of an electric circuit, is exposed to the air. Any chlorine present decomposes the potassium iodide and the iodine liberated converts the silver into silver iodide. The electric circuit is thus broken and by a suitable arrangement an audible warning may be given.
—W. G.

Carbon; Combustion of —— *in the presence of oxides.* E. Berger and L. Delmas. Bull. Soc. Chim., 1921, **29**, 68—77.

CERTAIN metallic oxides (CoO, CuO, PbO, Sb_2O_5, MoO_3; also $PbCrO_4$) when mixed with carbon to the extent of 4% of its weight facilitate the combustion of the carbon in air. Other oxides cause a diminution in the proportion of carbon monoxide produced in the combustion of the carbon; among the most active are those oxides which are known as good catalysts for various oxidation processes, *e.g.*, CuO, MnO_2, AgO.—W. G.

PATENTS.

Nitric acid; Process of concentrating dilute ——. H. Frischer. E.P. 137,834, 12.1.20. Conv., 31.8.16.

DILUTE nitric acid is vaporised by introducing it into a liquid of high boiling point, which is unaffected by it, such as phosphoric acid, sulphuric acid, or arsenic acid, the liquid being heated to a high temperature (140°—160° C.) and the nitric vapours conducted to a dephlegmator. Instead of causing the dilute nitric acid to pass direct into the vaporising apparatus, it may first be introduced into the dephlegmator, from which a part is drawn off as concentrated acid, and the remainder then vaporised by the heating liquid.—W. J. W.

Hydrofluosilicic acid gas; Absorber for ——. K. F. Stahl, Assr. to General Chemical Co. U.S.P. 1,367,993, 8.2.21. Appl., 18.8.17.

THE absorber consists of a tower with perforated bottom, the whole constructed of wood with an acid-resistant coating and filled with broken acid-resistant material.—C. I.

Phosphoric acid; Process for making ——. W. H. Allen. U.S.P. 1,368,379, 15.2.21. Appl., 17.6.20.

CRUSHED phosphate rock is mixed with sand and coke, and the mixture is strongly heated, phosphorus pentoxide being evolved.—W. J. W.

Soda containing water of crystallisation; Process for producing —— *or mixtures thereof with other substances.* A. Welter. E.P. 136,841, 18.12.19. Conv., 23.3.18.

A FINELY divided steam jet, shower of snow, or spray of water or of a solution of the salt which it is desired to mix with the soda, *e.g.*, water-glass, is directed on to soda ash which is kept in motion to prevent caking. The process may be carried out in a tower, or the spray may be used to blow the soda ash into a powder chamber, or the material may be sprayed on a conveyor belt provided with rakes, or in an agitator. In all cases cooling is necessary. A washing powder fit for sale is thus produced without further treatment.—C. I.

Ammonium perchlorate; Manufacture of ——. L. M. E. Wang. E.P. 137,034, 21.11.19. Conv., 27.12.18.

To an aqueous solution of ammonium sulphate and sodium perchlorate at a temperature below 100° C. but considerably above that of maximum solubility of sodium sulphate, further quantities of the reacting salts are added. The precipitated sodium sulphate is then separated from the solution, from which by cooling ammonium perchlorate is recovered, and the process is repeated. Alternatively, the hot mother liquor may be treated in separate portions with the additional quantities of sodium perchlorate and ammonium sulphate, after which the solutions are mixed.—W. J. W.

Hydrogen sulphide; Production of —— *from sulphurous gases.* J. G. Macleod. From W. J. Browning. E.P. 158,288, 31.7.19.

SULPHUROUS gases formed by the combustion of pyrites etc. are passed through incandescent carbonaceous matter, the heat of which is maintained by its own combustion. A regulated quantity of oxygen and, if necessary, water vapour is mixed with the sulphurous gases.—C. I.

Cyanides; Manufacture of ——. O. L. Barnebey. U.S.P. 1,355,642, 12.10.20. Appl., 19.3.19.

ACTIVATED carbon, sodium carbonate, and a catalyst, *e.g.*, iron, are heated in an atmosphere of nitrogen. The activated carbon is prepared by heating carbon in presence of steam or carbon dioxide above 700° C.
—C. I.

Nitrates; Process for fixation of ——. C. H. Buettner. U.S.P. 1,368,019, 8.2.21. Appl., 6.3.19.

NITROGEN and oxygen are brought into contact with water in small quantities, and the mixture is subjected to the action of the electric arc.—W. J. W.

Nitrogen compounds with hydrogen and oxygen; Preparation of —— *by the use of a titanium catalyst.* F. Hlavati and F. J. G. Oehlrich. G.P. 328,945, 5.9.16. Addn. to 275,343.

EITHER spongy metallic titanium or finely divided titanium carbide is used as catalyst without any carrying medium.—C. I.

Alkali-metal compounds; Process of obtaining water-soluble —— *from water-insoluble substances.* H. S. Blackmore, Assr. to Kali Co. of America. U.S.P. 1,357,025, 26.10.20. Appl., 14.12.18.

SILICATES insoluble in water and containing an alkali metal are heated under pressure with water and a non-acid metal silicofluoride, *e.g.*, magnesium silicofluoride. After filtering and cooling, potassium silicofluoride, sparingly soluble in cold water, separates, and this is subsequently converted into more soluble salts, such as the carbonate, sulphate, etc.—C. I.

Chlorides of potassium or other metals; Process for obtaining ——. W. A. Schmidt, Assr. to International Precipitation Co. U.S.P. 1,367,836, 8.2.21. Appl., 29.4.18.

POTASSIUM chloride is recovered from material containing alkali chlorides and sulphates by adding a chloride less volatile than potassium chloride. The mixture is heated and the whole of the potassium recovered as chloride vapour.—C. I.

Potassium nitrate and mixtures of salts containing potassium and nitrogen; Manufacture of ——. Badische Anilin u. Soda Fabrik. G.P. 310,601, 8.11.20. Addn. to 306,334 (J., 1921, 179 A).

BY cooling a hot solution of 98·5% ammonium nitrate, 204 pts.; 98·7% potassium chloride, 206 pts.; and water, 425 pts., to 2° C., 165 pts. of 99% potassium nitrate is recovered. On evaporating the mother liquor a mixture is obtained which contains about 36% of potassium nitrate, 55% of ammonium chloride, 8% of potassium chloride, and 1% of sodium chloride, and which has good keeping properties in a moist atmosphere.—W. J. W.

Cooling apparatus for hot solutions of potassium salts etc. H. Daus. G.P. 329,479, 15.2.20.

THE solution is forced through a nozzle giving a jet in the form of a hollow cone, while cooling air is sucked or driven up the centre of this cone and through the solution.—C. I.

Thorium nitrate; Process of manufacturing ——. C. W. Davis, Assr. to The Mantle Lamp Co. of America, Inc. U.S.P. 168,243, 15.2.21. Appl., 16.9.18

A RARE earth metal, *e.g.*, thorium, is separated from a mixture containing it by treatment with an alkali carbonate in presence of a phosphate.—C. I.

Inorganic materials [containing iron]; Process of purifying ——. G. A. Hulett. U.S.P. 1,368,396, 15.2.21. Appl., 22.3.19.

IRON and other impurities which form volatile chlorides are removed by the action of a current of phosgene at 350°—600° C.—C. I.

Bleaching powder; Process and apparatus for the manufacture of ——. E. Sidler. G.P. 329,178, 13.12.17.

THE chlorinating chamber contains a series of superimposed plates and stirring arms, which continuously turn over the lime and rake it from the sides towards the middle on one plate and from the middle towards the sides on the next lower one and so on. The lime is charged on to the top plate, and is gradually raked down from one plate to the next to the bottom of the chamber, the chlorine being passed in the same direction.—A. R. P.

Ammonium sulphate; Preparation of powdered non-caking ——. A.-G. für Anilinfabr. G.P. 329,359, 27.5.19.

SOLUTIONS of ammonium bisulphate or sulphuric acid are sprayed through ammonia gas under pressure.—C. I.

Hydrogen and oxygen; Catalytic purification of ——. Consortium für Elektrochem. Ind. G.P. 329,177, 17.10.19.

THE gases are passed over heated mixtures of copper and silver, or of their compounds, with or without compounds of silicon, cerium, and zirconium. The porcelain masses carrying the catalyst require to be heated to 200°—350° C., according to the composition of the latter.—C. I.

Sodium-ammonium sulphate; Separation of the double salt —— *into sodium sulphate and ammonium sulphate. Separation of sodium sulphate and ammonium sulphate from the double salt sodium ammonium sulphate.* Soc. Ind. de Prod. Chim. E.P. 128,895, 27.9.18 (Conv., 22.6.18), and 158,282, 6.1.19. VIII.—GLASS ; CERAMICS.

Glass; Development of various types of ——. C. J. Peddle. J. Soc. Glass Tech., 1920, 4, 299—366.

THE preparation, stability, and optical properties of the following series of alkali, lead oxide, silica glasses were studied:—100 SiO_2, 40 Na_2O, xPbO; 100 SiO_2, 20 Na_2O, xPbO; 100 SiO_2, 40 K_2O, xPbO; 100 SiO_2, 20 K_2O, xPbO; 100 SiO_2, 20 Na_2O, 20 K_2O, xPbO; 100 SiO_2, 10 Na_2O, 10 K_2O, xPbO, where x varied from 5 to 40 mols. All the glasses can be founded above 1350° C. and exhibit corrosive action on pot clay, increasing with increased alkali content. Glasses of the soda series tend to devitrify if containing more than 65% SiO_2, and those of the mixed alkali series if the silica content exceeds 61%. The potash glasses show no signs of devitrification, but all film badly on prolonged heating at 900° C. In all cases density and refractive index increase with increasing content of lead oxide, the rate of increase falling as the lead oxide content rises. Dispersion also increases with increase of lead oxide, but ν falls as η_D rises. Comparison of the above and also of further series containing equal percentage amounts of potash and soda

showed all the soda glasses to have higher densities than the corresponding potash glasses, the mixed alkali glasses having intermediate values. In the equimolecular series the potash glasses have slightly higher refractive index and total dispersion, but in the series containing equal weights of alkali the soda series have higher refractive index and dispersion. The refractive index and dispersion of the mixed alkali series are intermediate between those of the soda and the potash series. The solubility of the glasses in water decreases as the content of lead oxide or silica rises but increases rapidly with increase of alkali. Solubility tests prove the following glasses to be of first-class durability for optical requirements:—Glasses of the molecular formulæ, 20 Na_2O, 30 PbO, 100 SiO_2; 20 Na_2O, 40 PbO, 100 SiO_2; 10 Na_2O, 10 K_2O, 30 PbO, 100 SiO_2; 10 Na_2O, 10 K_2O, 40 PbO, 100 SiO_2; 20 K_2O, 40 PbO, 100 SiO_2; also glasses of the percentage compositions, SiO_2 50, Na_2O 10, PbO 40; SiO_2 50, K_2O 10, PbO 40; SiO_2 40, Na_2O 10, PbO 50; SiO_2 40, K_2O 10, PbO 50; SiO_2 60; Na_2O 5, K_2O 5, PbO 30; SiO_2 50, Na_2O 5, K_2O 5, PbO 40; SiO_2 40, Na_2O 5, K_2O 5, PbO 50. The first two of the molecular series approximate in optical constants to well-known Schott glasses. The Benrath formula 6 SiO_2, 1 R_2O, 1 PbO does not give a very stable type of alkali-lead oxide-silica glass, a more satisfactory one being 5 SiO_2, 1 R_2O, 1·5 PbO.—A. C.

Glass composition; Rate of change of —— following a change in batch composition. J. Currie. J. Soc. Glass Tech., 1920, 4, 382—387.

On changing the composition of a lime-soda batch supplying a tank furnace so as to increase the lime content of the glass produced, the relationship between capacity of tank, rate of feeding in the fresh batch, and the time taken for the glass worked out to approximate to the desired new composition, was noted. The furnace capacity was 106 tons, the weekly addition of batch 95 to 110 tons (containing only about one-eighth of added cullet from the working end). The change of composition was not quite complete in 3 months.—A. C.

Glass; Influence of silica on the annealing temperature of ——. S. English, F. W. Hodkin, C. M. M. Muirhead, and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 387—391.

A series of simple sodium silicate glasses ranging from $2Na_2O,4SiO_2$ to $2Na_2O,10SiO_2$ was examined. The upper annealing temperature was found to rise with increase of silica content, the rate of increase being most rapid between $2Na_2O,4SiO_2$ and $2Na_2O,7SiO_2$.—A. C.

Glass; Devitrification of —— as a surface phenomenon. Repair of crystallised glass apparatus. A. F. O. Germann. J. Amer. Chem. Soc., 1921, 43, 11—14.

Devitrification of glass in a blowpipe flame is not due to the formation of crystal nuclei in the mass of the glass but is a surface phenomenon due to the expulsion of water and carbon dioxide, and possibly, when the heating is prolonged, to the volatilisation of sodium oxide. Devitrification may be prevented by washing the parts to be heated with dilute hydrofluoric acid, thus removing the surface layer. In this way old apparatus which has been broken may be repaired.—J. F. S.

Clay; Ageing of ——. H. Spurrier. J. Amer. Ceram. Soc., 1921, 4, 113—118.

The gases recovered by the method described previously (J., 1919, 176 A, 633 A) from clay that had been pugged 24 hrs. previously were found to contain both carbon monoxide and carbon dioxide. The evolution of carbon dioxide continued for over 34 days after pugging and, like the change of plasticity, proceeded more rapidly between 80° and 90° F. than below 60° F. By replacing water by non-aqueous liquids the development of plasticity was inhibited entirely, suggesting that hydroxyl ions must be present in order to develop plasticity. The addition of a dilute solution of hydrogen peroxide to the clay slip produced a pronounced increase of viscosity and stimulated the growth of filamentous algæ with the consequent evolution of both carbon monoxide and carbon dioxide. The change of plasticity of clays with time seems due, in some way, to the growth of such algæ, though the copious formation of carbon dioxide is somewhat confusing, because the introduction of free carbon dioxide reduces the plasticity of clays. The ratio of the amounts of alumina and silica dissolved by caustic potash was found for the three clays tested to decrease rapidly with diminishing plasticity and might therefore be used as a quantitative measure of plasticity.—H. S. H.

Aluminous fireclays; Effect of added felspar on the shrinkage and porosity of —— after being fired at high temperature. E. M. Firth and W. E. S. Turner. J. Soc. Glass Tech., 1920, 4, 392—400.

In a previous paper (J., 1920, 628 A) the authors had noted that, of clays which they examined, those of high alumina content showed, with two exceptions, the widest range of porosity on firing. It is now shown that if 1 or 2% of felspar is added to the two exceptional aluminous clays (to act as a flux during firing) the shrinkage is rendered more uniform, and there is a considerable increase of porosity range.—A. C.

Spalling [of bricks]; Study of ——. R. M. Howe and R. F. Ferguson. J. Amer. Ceram. Soc., 1921, 4, 32—46.

Bricks were heated in the door of a furnace and then rapidly cooled, some by standing in water to a depth of 5 in. and others by directing a jet of cold air from a blower on them. In each case the loss in weight due to the detachment of particles was taken as a measure of the amount of spalling. Both spalling tests gave similar results. With bricks made from the same clay, lightly burned bricks spalled less than hard burned bricks, and resistance to spalling was increased by using coarser ground material. These tests lead to accurate conclusions where the same fireclays are involved, but misrepresent the facts observed in works service when different clays are concerned. These discrepancies disappeared when the specimens were heated for 5 hrs. at 1400° C. before testing. Two fireclays which produced bricks which were very resistant to spalling when in use were characterised by a constancy in porosity over a wide range of temperature, and were therefore considered very resistant to vitrification. When firebricks spall in service the pieces are usually dense or vitrified. The connexion between vitrification and spalling was established by experiments. Fireclays which undergo a slight change in porosity when heated over a wide range of temperature have a very slight tendency to vitrify, and are particularly adapted to the manufacture of non-spalling bricks.—H. S. H.

Spalling [of firebrick]; Use of plastic clay grog in preventing ——. R. M. Howe and S. M. Phelps. J. Amer. Ceram. Soc., 1921, 4, 119—126.

A medium dense burning clay was calcined at cone 8, then ground and mixed with plastic clay in various proportions up to 40%, and the bricks made therefrom were burned at cone 8. As the percentage of grog increased the bricks became more porous and mechanically weaker, but showed less drying and burning shrinkage. The water spalling test was too severe for this type of brick, and the difference in the results obtained was too slight to permit

definite conclusions being drawn. An air-spalling test of the bricks showed that the grog increased the resistance to spalling about 5% for each 1% of grog added.—H. S. H.

Silica brick; Note on ——. D. W. Ross. J. Amer. Ceram Soc., 1921, 4, 65—67.

OBSERVATIONS were made during an extended period on the silica bricks in the crown of a tank furnace used in the manufacture of bottle glass. It was found that great care was necessary in heating up a new crown, due both to the large expansion of the whole crown and to unequal expansion from place to place, some portions expanding considerably more than others. After having been in use for 18 months (or more) a crown could usually be cooled without disruption if the temperature did not drop too suddenly after the fires were turned off. On reheating the crowns only expanded one-half as much as they did in the first heating, and local non-uniformity was practically absent. When a crown had been cooled after being in use for 18 months a large percentage of the bricks were broken in two or contained a source of weakness approximately midway between the inside and outside of the crown. Microscopical examination of the bricks after 18 months' service indicated that they were practically all tridymite, whereas the unused bricks were largely cristobalite and quartz.—H. S. H.

Dolomite and magnesite; Experiments in dead-burning ——. H. G. Schurecht. J. Amer. Ceram. Soc., 1921, 4, 127—151.

DOLOMITE is difficult to dead-burn owing to its tendency to disintegrate, due partly to the inversion of β- to γ-calcium orthosilicate on cooling, with a 10% volume increase, and partly to gradual slaking owing to the hydration of free lime. With all the fluxes tried (flue dust, iron ore, basic open-hearth slag, kaolin, roll-scale) dolomite passed through a 100-mesh sieve gave greater resistance to slaking than when sieved through 8-mesh. This resistance decreased with increasing temperature of calcination by an amount which seemed to depend on the silica and alumina content of the flux, being greatest for basic open-hearth slag and kaolin, less for flue dust and iron ore, and least for roll-scale. This result is possibly due to the formation of hydraulic compounds with lime, similar to those found in Portland cement. The stability also varied with the proportions of flux used, being greater, as a rule, for smaller proportions. The magnesite used contained about 11% of lime, and increasing the calcination temperature decreased the tendency of the product to increase in weight on exposure to the atmosphere. Roll-scale was a more effective flux for magnesite than was iron ore, probably because of its lower silica content. The shrinkage and porosity curves for mixtures of dolomite with flue dust, iron ore, and roll-scale respectively were very similar. The higher the proportion of flux, the lower was the temperature required to obtain a product of maximum shrinkage and minimum porosity. Kaolin and basic open-hearth slag behaved peculiarly in that vitrification depended more on the burning temperature than on the proportion of flux used. Kaolin was more effective than an equal weight of iron ore or flue dust in promoting vitrification. With magnesite and roll-scale the shrinkage was much less and the porosity much greater than with dolomite and roll-scale, the lime of the dolomite being more actively attacked by roll-scale than was magnesia. Mixtures of dolomite and iron ore were passed through a 100-mesh sieve, calcined to cone 20, and moulded into bricks with 5% of caustic lime, sodium silicate, or magnesium chloride. Owing to slaking all the bricks cracked on drying. This was avoided by "ageing" the batches with excess of water for at least three weeks. Hydration had then taken place and no cracking occurred on drying. Bricks made with magnesium chloride were then very strong. On burning to cone 18 all cracked excessively, due to high shrinkage, but withstood storage for 4 to 6 months. Bricks pressed from calcined dolomite with 12% of dehydrated coal tar withstood storage for about 4 months. They showed less shrinkage and cracking on firing than similar bricks made with water, and if dipped in tar to protect them from moisture, could be stored for 5—6 months.
—H. S. H.

Terra-cotta; Effect of glaze composition on the crazing of ——. E. C. Hill. J. Amer. Ceram. Soc., 1921, 4, 25—31.

THE body used contained 35% of grog and was composed of equal parts of a fat plastic clay which had shown a tendency to produce crazing and a clay which might be considered medium in this respect. The test pieces were pressed from this body, and when dry sprayed with the engobe regularly used, and over this was placed a heavy coat of glaze. The specimens were fired to cone 5½ in 40 hrs. and cooled in about the same time; two burns were made. The glaze used as a base had the composition (0·28 K_2O, 0·21 CaO, 0·21 ZnO, 0·10 MgO, 0·20 BaO); (0·33 Al_2O_3), (2·53 SiO_2, 0·10 SnO_2). Comparing the effects of equal molecular additions of the various components of the glazes, it was found that zinc oxide and felspar overcame crazing, the former being the more effective. Magnesia, barium monoxide, and lime tended to produce crazing, magnesia having the greatest tendency, and the effect of barium monoxide being somewhat greater than that of lime. Tin oxide had no effect on the crazing. Additions of small amounts of clay were more effective in overcoming crazing than much larger additions or substitutions of the other components. Increase of flint (per molecular equivalent) was less effective in overcoming crazing than increase of either clay, zinc oxide, or felspar, although, generally, considerably more flint than clay or zinc oxide could be added without appreciably changing the maturing of the glaze. The results indicated that in many cases increase of flint will not overcome crazing in a glaze.—H. S. H.

PATENTS.

Sheet glass; Process and apparatus for the manufacture of ——. R. L. Frink. E.P. 157,598, 6.11.19.

A RECTILINEAR metallic bait having a coefficient of expansion different from that of glass is lowered into a bath of molten glass and then raised. An electric current is passed through the bait, and is so regulated that the temperature of the bait is such that the glass in contact with it is kept from setting, and is thus able to accommodate itself without rupture to any relative displacement of the bait due to a change in temperature. The bait is raised at such a speed that a sheet of glass of substantially uniform thickness is produced. The edges of the sheet adjacent to the bath are kept in adhesive contact with electrically heated "shoes." The tendency of the glass to draw in at the sides owing to surface tension is thus counteracted, and the width of the sheet is maintained substantially constant. The sheet is severed from the bath, and the bait and the attached sheet of glass are moved in a horizontal direction out of alinement with the bath. Successive portions of desired length are then cut from the lower end of the sheet.—H. S. H.

Glass melting tanks or furnaces. C. Truel. E.P. 157,684, 15.6.20.

THE flues of a glass melting furnace are placed at the same end of the furnace and at about the same

level as the burners for liquid or gaseous fuel. The flames or products of combustion pass across the furnace to the opposite end, and are then brought back over the entire length of the furnace by the draught of the flues to the same end as that from which they were originally projected.—H. S. H.

Quartz glass; Process of producing articles of ——. J. Scharl, Assr. to General Ceramics Co. U.S.P. 1,368,990, 15.2.21. Appl., 18.9.18.

Articles of quartz glass are made by heating plastic quartz in an electric resistance furnace about a resistance core, a space between the quartz and the resistance core being formed by inserting a heat-resisting tube, impervious to gas, to allow the escape of the gas formed during the heating. —A. B. S.

Tunnel furnaces, kilns, ovens and the like. H. Francart. E.P. (A) 157,474 and (B) 157,475, 19.12.18.

(A) In the interior of a tunnel furnace are a number of hollow flanges which serve as a part or the whole of the combustion chambers or hot gas flues. The hollow flanges are arranged in series so as to leave between them a series of vertical cavities along the oven with a view to favouring both radiation and efficient working. The flanges are provided with pipes traversing them from one vertical cavity to another in order to increase the circulation of the gaseous medium and to increase the heating surface. The pipes may be inclined so that the heated gas as it rises in the pipes also moves forward in a longitudinal direction. (B) A tunnel furnace has a number of solid flanges projecting inwards from the fixed walls so that vertical cavities are formed between the flanges. Spaces for combustion are provided at the bottom of the cavities. The flanges may be provided with suitable projections so as to increase the surface of radiation. Conduits are arranged at the bottom of the flanges so as to favour the longitudinal displacement of the gaseous mass, and this is also facilitated by inclining the flanges from the bottom upwards towards the entrance of the oven. By extending the flanges below the level of the sole of the furnace an efficient circulation is obtained in a low oven such as is used in annealing steel.—H. S. H.

Kilns of the tunnel type; Continuous ——. R. C. Metcalfe. E.P. 158,499, 16.9.20.

A continuous tunnel kiln is built in sections each at an angle to the preceding one, and is provided with turntables and pushing and engaging devices to facilitate the transference of the cars from one section to another.—A. B. S.

Tunnel-kiln. P. d'H. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,366,369, 25.1.21. Appl., 17.12.19.

A tunnel-kiln having an elongated kiln chamber has a heating zone and a goods cooling zone at one end of the heating zone. An air preheating and goods cooling conduit extends along the cooling zone, and a combustion chamber, separated by a heat-conducting wall from the kiln chamber, extends along the heating zone. A fan or blower having its inlet connected with the cooling zone and its outlet connected with the combustion chamber minimises the pressure differences tending to cause leakage flow between the kiln chambers and the combustion chamber or conduit.—H. S. H.

Tunnel-kiln. A. C. Shepard, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,366,424, 25.1.21. Appl., 26.1.20.

A tunnel-kiln has masonry benches extending longitudinally at the sides of a pathway at the bottom of the kiln for the trucks carrying the ware. On each side of the benches is an elongated combustion chamber from which extend pipes connected at their other end with a "header." Each bench is formed with a channel having uprising end portions which communicate one with the interior of the "header" and the other with the interior of the combustion chamber at the opposite ends of the pipes, and also with an outlet from the channel for the products of combustion. Dampers regulate the relative amounts of the products of combustion which pass from the combustion chamber by means of the pipes and a portion of the channel to this outlet and through the by-pass about the pipes formed by the remaining portion of the channel.—H. S. H.

Kilns; Arrangement for utilising the waste gases in ——. F. Mayer. G.P. 328,985, 7.9.15.

Water-pipes are fixed in heating flues in the crown of the kiln, the flues being divided into cells which are of the same length as the burning chamber beneath and are in open connexion with the corresponding combustion chamber.—A. B. S.

Brick-burning; Apparatus and method for ——. H. O. Robinson and C. Steadman. U.S.P. 1,367,756, 8.2.21. Appl., 30.12.13.

The bricks in a kiln are burned by a method comprising the following stages:—Using a low fire and forcing the heat by artificial draught throughout the entire stack; increasing the heat to full fire for 24—36 hrs.; forcing the heat in the lower courses of bricks upwards through the upper courses by means of artificial draught; continuing the heating until the lower courses of bricks are fully burned; and completing the burning of the upper courses by blowing the heat from the lower part into the upper part of the kiln.—A. B. S.

Joints for earthenware or ceramic materials. W. Hayhurst. E.P. 158,427, 24.11.19.

Earthenware or other ceramic articles may be joined together or to metal by filling a recess in the ceramic article with a cement composed of a phenolic aldehyde condensation product combined with about one-third of a suitable filling material such as asbestos. The cement is hardened by heating it to 100°—150° F. (38°—65° C.) for 2—3 hrs., and is then tapped, threaded, or otherwise machined in order that it may be attached to the metal or other article.—A. B. S.

Glass; Method and apparatus for forming sheet ——. E. Danner. E.P. 159,114, 26.5.20.

IX.—BUILDING MATERIALS.

Plaster; Normal consistency of sanded gypsum ——. W. E. Emley and C. F. Faxton. J. Amer. Ceram. Soc. 1921, 4, 152—157.

Twelve plasters were prepared containing various proportions of gypsum and sand, and to samples of each five different amounts of water were added. The consistencies, determined with a Southard viscosimeter (Amer. Soc. Testing Materials No. C 26 —19T, 1919), and the tensile strengths of the set plasters, were tabulated. The results varied both with the kind of gypsum and with the fineness of the sand, but the opinion is expressed that material of the proper consistency to be used for plastering would show a "slump" of ½ in. when tested in the Southard viscosimeter.—H. S. H.

Patents.

Asphaltic cement or bituminous composition for road-making, paving, flooring, roofing, and other purposes. M. Talbot-Crosbie. E.P. 158,674, 7.11.19.

An asphaltic cement is formed by mixing heated bitumen or asphalt (45%) with purified chalk (55%).

A small quantity of linseed oil or other vegetable oil may be added to improve the weather-resisting properties. Sand may be mixed with the composition before use.—A. B. S.

Silicated cement; Process of manufacturing ——. S. Matsuo. U.S.P. 1,367,984, 8.2.21. Appl., 9.8.17.

Hot Portland cement clinker is added to wet sand which has been washed in hydrochloric acid, and the mixture is cooled and ground.—A. B. S.

Shaft-furnace for cement and similar material. A. Barth. G.P. 328,319, 20.5.19.

In a shaft-furnace of the type in which the grate is fixed and the shaft rotates, the lower part of the shaft is provided with arms arranged like the spokes of a wheel. Cold air is circulated through the arms and through passages in the casing enclosing the shaft. The arms are fixed to the shaft and hence rotate above the grate, and serve to promote uniform distribution of the material and to prevent agglomeration of large lumps.—W. J. W.

Shaft kilns for burning lime, magnesite, cement, etc.; Device for preheating the air used for combustion in ——. G. Polysius. G.P. 328,320, 12.2.18.

The air is drawn downwards through an annular space formed by iron rings around the cooling zone, and is thereby heated before it enters the lower end of the kiln.—A. B. S.

Marl; Method of burning ——. J. Mühlen. G.P. 329,167, 26.2.18.

The portion of the calcined marl which can only be slaked with difficulty is finely ground, mixed with the portion which slakes readily, and the mixture is slaked under such conditions that a dry powder is produced.—A. B. S.

Waterproof kieselguhr; Production of ——. W. Bünte and W North. G.P. 329,410, 24.11.18.

Granulated or powdered kieselguhr is mixed with lightly ground pitch and the mixture is heated. The product is used as an insulating agent against heat, cold, moisture, and noise.—A. B. S.

Cement; Slow-setting —— *and method of producing same.* H. D. Baylor. E.P. 158,390, 8.11.19.

See U.S.P. 1,323,952 of 1919; J., 1920, 113 A.

Wood-like material. U.S.P. 1,357,647. *See* V.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

High frequency induction steel furnace. E. F. Northrup. Chem. and Met. Eng., 1921, 29, 309—311.

The Ajax-Northrup high frequency induction furnace operates with a current of from 10,000 to 25,000 cycles per sec., obtained through a suitable high frequency converter. The furnace consists essentially of an inductor coil in the shape of a truncated cone, which fits loosely round a crucible of similar shape. The coil itself is composed of 37 turns of ⅜-in. copper tubing, flattened, and wound edgeways. During the heating process water is circulated through the coil to keep the resistance low. The inside of the inductor coil is lined with a cylinder of micanite about ¼ in. thick, and a space of about ½ in. between the crucible and the coil is filled with a suitable powdered heat insulator, *e.g.*, lampblack or powdered magnesia. The whole is encased in a box of stout asbestos board. As the heating of the crucible contents is due entirely to the large induced currents, the metal to be melted must not be in the form of powder. Turnings, or pea-sized material, offer the most suitable form for efficient use. If the metal is magnetic there is a further development of heat in the earlier stages due to the hysteresis losses caused by the rapid reversals of the magnetism, and as soon as the metal becomes molten, an active circulation, due to electromagnetic forces, is set up, thus effecting thorough mixing of the melt. No conclusive tests on the maximum temperature attainable have been made, but 1800° C. is given as a conservative figure. Such metals as brass, copper, gold, and silver have too high conductivity to be melted efficiently by direct induction, and for this class of metals the non-conducting crucible is replaced by a crucible moulded from carbon or graphite. In this case the heat is generated directly in the walls of the crucible and is transmitted to the metal by conductivity and radiation.—C. A. K.

Case-hardening; Nitrogen and ——. H. Fay. Chem. and Met. Eng., 1921, 24, 289—290.

Experimental figures are given in support of the view that case-hardening is a nitrogenising as well as a carbonising process. Hurum found that after heating a low carbon steel in a cyanide bath for 10 mins. at 830° C., the outside layer contained 0·57% N. Nitrogen appears to penetrate at a slightly greater rate than carbon. Results obtained by treating steel by Shimer's cyanamide process (U.S.P. 1,279,457—8; J., 1918, 772 A) show that diffusion of carbon takes place below Ac1 (at 650° C.), and that nitrogen combines with iron and diffuses below the Ac1 point. The nitrogen content decreases with rise of temperature, indicating that equilibrium is reached at some lower temperature. In these experiments the maximum nitrogen content (0·579%) was attained at 750° C.—C. A. K.

Steel welds; "Blue brittleness" of ——. C. Frémont. Comptes rend., 1921, 172, 368—370.

By electrical welding under pressure sufficient to cause all the metal which is oxidised at the beginning of the operation to flow out laterally, a joint is obtained free from oxidised metal. In some cases this gives a satisfactory joint, but in other cases there is brittleness due to deformation within a critical temperature range. At a short distance from the joint, a region, for which the temperature is between 200° and 450° C., undergoes deformation under the action of the pressure necessary for the welding, and "blue brittleness" results. This would be avoided by choosing a steel which is not subject to blue brittleness (*cf.* J., 1905, 31).—W. G.

Corrosion of steel ranges. O. W. Storey. Trans. Amer. Electrochem. Soc., 1921, 13—21. [Advance copy.]

The metal walls forming the flues of a domestic range may suffer corrosion, either from direct oxidation due to excessive heating, or, more extensively, from the deposition of moisture and sulphurous and other acids during the periods of warming or cooling the flues. Protective coatings of vitreous enamel or magnetic oxide would prevent corrosion. Steels containing copper are much less corroded than plain carbon steels or "Armco" iron, the resistance of copper steels (containing up to over 2% Cu) to corrosion being shown as a straight line function of the copper content.—C. A. K.

Nickel steels; Electrical resistance of ——. A. Portevin. Comptes rend., 1921, 172, 445—447.

The electrical resistance of nickel steels is dependent to a considerable extent on the conditions of annealing. With steels containing 0·3—0·8% C and 7—15% Ni the resistance varied 10—40% according as the steel was heated to 1000° C. and cooled during 4—5 hrs., or heated to 1300° C. and cooled

during 3 days. This variation in the electrical resistance may or may not be accompanied by characteristic modifications of the micro-structure. Curves are given showing the variation in resistance of nickel steels according to their carbon and nickel content.—W. G.

Nitric acid and copper; Reaction products of ——. L. S. Bagster. Chem. Soc. Trans., 1921, **119**, 82—87.

THE gaseous products from the reaction of copper with $5N$ and $6N$ nitric acid consist almost entirely of nitrogen trioxide. With $14{\cdot}5N$ acid, about 85—)% of nitrogen peroxide is formed, the residue eing trioxide. From $10N$ acid, 15—20% of perxide is produced; and from $8N$ acid, a slightly naller amount.—W. J. W.

opper; Action of reducing gases on heated ——. H. Moore and S. Beckinsale. Inst. Metals, March, 1921. [Advance copy.] 22 pages.

AMPLES of copper containing 0·08—0·02% of xygen, and others of deoxidised copper, were subected to the action of hydrogen, coal gas, and arbon monoxide at different temperatures, and he effects observed microscopically and by echanical tests. The oxygen was always present s small globules of cuprous oxide uniformly disributed. The first observed effect of the action of educing gases on copper containing oxygen was an pparent slight expansion of the envelopes of the xide globules. This was followed by the formation f cracks which extended to form a network. In opper containing 0·07% of oxygen the effect of educing gases began to be important at about 00° C. A markedly injurious effect was produced ith even so low an oxygen content as 0·02%, but or a given effect a greater time and/or a higher emperature were needed than with higher perentages of oxygen. Coal gas was intermediate etween hydrogen and carbon monoxide as regards epth of penetration in a given time, but the actual eakening effect seemed to be greater than with ither of these other gases. Samples of copper conaining small percentages of Zn, Mn, Al, or P, were ntirely free from globules of cuprous oxide, and ere not affected injuriously when heated in reucing atmospheres. Zinc would appear to be the ost generally suitable deoxidiser, 0·10% being ufficient to confer complete immunity against the ction of reducing gases, and for many purposes opper containing up to about 3% Zn is a better aterial than commercially pure copper.—T. St.

rass and other copper alloys; Season-cracking of ——. H. Moore, S. Beckinsale, and C. E. Mallinson. Inst. Metals, March, 1921. [Advance copy.] 91 pages.

HE season-cracking of brass appears to require oth that the metal shall be in a state of stress and hat it shall be subject to the action of some gent which selectively attacks the intercrystalline aterial. Normal corrosion, such as is produced y many acids, for example, does not give rise to eason-cracking. The most usual agents are probbly ammonia compounds derived from the tmosphere, but in studying the liability of brasses o develop cracks a 1% solution of mercurous nitrate s very convenient. A coating of lacquer is not a rotection against season-cracking, but nickellating appears to give complete protection proided the coating is continuous and sufficiently hick. Surface defects do not appear to contribute o the development of season-cracks to any imortant extent. Season-cracks almost invariably ollow an intercrystalline path, this being a most arked and characteristic feature. The greater he degree of hardening by cold-work, the less is he brass affected by the intercrystalline weakening action of ammonia or mercury. Liability to the development of season-cracks appears to diminish as the zinc content is reduced: copper and zinc-copper alloys containing less than about 10% Zn are unlikely to fail by the development of season-cracks in service. Within the limits of, say, 25 to 45% Zn little improvement in resistance to season-cracking is likely to be obtained by changes in composition or treatment, if the state of initial stress is not affected. The apparent advantage of harder worked brass is largely discounted by the higher stresses which are likely to exist in harder brass, if steps are not taken to remove them. A suitably controlled low-temperature annealing, which will remove stress without affecting the hardness, appears to be the most effective safeguard against failure by season-cracking, and might well be applied to all brass articles made by cold-work operations capable of inducing permanent internal stress. The authors consider that the results obtained by them afford strong support to the hypothesis of an intercrystalline material differing essentially in its properties from the crystals themselves, and that this material appears to be identical in its properties with Beilby's amorphous phase found in surface films. They have found no evidence which would indicate that season-cracking is the result of viscous flow of the intercrystalline cement. The undoubtedly intercrystalline character of season-cracks appears to be fully explained by the selective weakening action of a chemical substance on the intercrystalline material. In testing brass samples by the mercurous nitrate test for liability to develop season-cracks the standard method adopted by the authors was to pickle the specimen first for 30 secs. in a bath containing 40 vols. of nitric acid (sp. gr. 1·42) and 60 vols. of water, then to wash it thoroughly in water, and immerse it, without drying, in a solution made up with distilled water, containing 1 g. $Hg_2(NO_3)_2,2H_2O$ crystals and 1 c.c. of nitric acid (sp. gr. 1·42) in 100 c.c.—T. St.

Copper with tin; Constitution of the alloys of ——. *Parts III. and IV.* J. L. Haughton. Inst. Metals, March, 1921. [Advance copy.] 22 pages. (*Cf.* J., 1915, 358.)

THE author has investigated the copper-tin alloys containing from 30 to 100% of Sn at temperatures below about 250° C. Thermal curves of the carefully annealed alloys were taken in a furnace arranged to give a uniform temperature gradient between 500° C. and 50° C., and in some cases electrical resistance measurements were also made. From the results the author has plotted an equilibrium diagram. In discussing the thermal curves obtained it is pointed out that the 210° C. and 190° C. arrests do not appear to be constant temperature arrests as is the case with the eutectic. The range of composition over which the 190° C. point is observed corresponds to the range in which the ϵ constituent occurs, and the magnitude of the heat evolution increases with addition of tin, so far as can be observed, until the point at which the alloy consists of pure ϵ (say about 60% Sn), after which it decreases in magnitude once more. This fact appears to point to a polymorphic change of ϵ at 190° C., but no evidence as to the meaning either of the 210° C. arrest point or of that at 190° C. was obtainable from an examination of the microstructure of the alloys. Also, no evidence was obtained of the existence of the allotropic transformation in tin at 161° C. With regard to the extreme right-hand portion of the diagram, microscopical examination of alloys annealed at different temperatures leads the author to draw the limit of the solid solution of copper in tin at 99·8% Sn and 195° C., and to indicate a slight falling off of solubility with falling temperature. The

composition of the pure eutectic as determined by Heycock and Neville (J., 1896, 810) and recently confirmed by Guervich and Hromalko (Bull. Amer. Inst. Min. Met. Eng., 1919, No. 152), viz., 99% Sn, is accepted by the author, who, however, makes the melting point 227·4° C. as against 227·1° C., the value given by the latter investigators.—T. St.

Copper alloys; Plastic deformation of some —— at elevated temperatures. C. A. Edwards and A. M. Herbert. Inst. Metals, 9.3.21. [Advance copy.] 25 pages.

The indentations produced by a blow of 63 in.-lb. on test pieces of various copper-aluminium and copper-zinc alloys at temperatures between 16° and 900° C. were measured, and from these figures the Brinell hardness numbers were calculated. Graphs are given showing the relation between these numbers and the temperature for each of the alloys tested and the relation between the numbers and the composition of the alloys in each series. In general in both series the hardness diminishes with rise of temperature, the rate of falling-off depending on the composition of the alloys. In the zinc-copper series a sharp break in the curve is noticed at 470° C. in alloys containing more than 34% Zn, corresponding to a transformation in the β constituent. A similar break is noticed in the copper aluminium series somewhere about 550° C. with alloys containing more than 12·4% Al.—A. R. P.

Aluminium sheet; Stages in the recrystallisation of —— on heating; with a note on the birth of crystals in strained metals and alloys. H. C. H. Carpenter and C. F. Elam. Inst. Metals, 9.3.21. [Advance copy.] 22 pages.

The structure of aluminium sheet (99·6% Al, 0·19% Si, 0·14% Fe) was examined during the various stages of rolling and after heating to temperatures from 200° to 600°C. for periods varying from 1 hr. to several months, and photomicrographs are given showing the changes that occur. On rolling, the original crystals of the cast metal are elongated in the direction of rolling but the crystalline structure of the metal does not disappear. Three distinct types of structure are produced on heating; the first visible change occurs when the metal is heated for long periods at 200° C. or for shorter periods at 250°—300° C. and is characterised by the general tarnishing of the surface, a granular structure, and the blurring of the original boundaries of the flattened crystals. If the metal is kept for a longer time between 250° C. and 300° C., new crystals, which appear white, commence to form in the old crystal boundaries, and eventually the whole metal recrystallises, the crystals being very much elongated in the direction of rolling. If the heating is carried out at a higher temperature, the crystals, while still being slightly elongated, are approximately equiaxed. From an examination of the recrystallisation of a worked aluminium-zinc alloy and a sample of 70:30 brass it was concluded that all new crystals originate either in crystal boundaries or in twin boundaries and that they grow indiscriminately into the surrounding old crystals. —A. R. P.

Spongy platinum; Preparation of ——. R. Feulgen. Ber., 1921, 54, 360—361.

A solution of chloroplatinic acid (5 g.) in water (5 c.c.) is mixed with formaldehyde solution (40%, 7 c.c.), and sodium hydroxide (5 g.) dissolved in water (10 c.c.) is added gradually. After remaining at the laboratory temperature for ½ hr., the mixture is heated for 15 mins. at 55° C. and then poured into a half-litre flask half filled with water. The latter is agitated violently for a few minutes which causes the precipitate to settle in coarse particles leaving an almost colourless supernatant liquor. The latter is decanted and the precipitate is washed with water strongly acidified with acetic acid; coarse particles are again formed which can now be washed as is necessary without showing any tendency to pass into colloidal solution. The metal is finally collected and dried in a vacuum over sulphuric acid. Great caution must be observed in the subsequent admission of air into the desiccator as the metal readily becomes incandescent owing to absorption of oxygen. Previous to use it is advisable to grind and wash it once more. A very active catalyst is thus obtained.—H. W.

Bearing metals. B. Simmersbach. Chem.-Zeit., 1921, 45, 216—219.

In an examination of the properties, and suitability for various applications, of gun-metal and white metal alloys, the influence of re-melting on their composition and characteristics has been investigated. With white metal, even after five fusions, no appreciable alteration in chemical composition was found; the copper was slightly higher, and the amounts of tin and antimony decreased, but the relative proportion of the last two metals remained unaltered. The temperature of fusion and the rate of cooling, however, appreciably affect the hardness and resistance of the alloy; the best results are secured by rapid cooling from a moderately high temperature. With gun-metal greater hardness was obtained by melting at 900° C. than at 700° C.; no appreciable difference was detected for temperatures between 400° C. and 700° C. The critical temperature is 782° C.; at or above this temperature rapidity of quenching the melt is of importance, and has a greater influence on the properties of the alloy than the amount of tin which it contains. Various applications of both gun-metal bronzes and white metal alloys are discussed, and many compositions for the latter are given.—W. J. W.

Calcium; Some notes on ——. P. H. Brace. Inst. Metals, 9.3.21. [Advance copy.] 16 pages.

A historical survey of the development of the metallurgy of calcium is given, together with the most important properties and applications of the metal. A method for the production of the meta from fused calcium chloride is described (*cf.* J., 1920, 370 A). Emphasis is laid on the necessity fo using a very pure anhydrous chloride, which shoul not contain more than traces of sodium, magnesium or aluminium chlorides.—A. R. P.

Gallium: its electrolytic behaviour, purification melting point, density, coefficient of expansion compressibility, surface tension, and latent hea of fusion. T. W. Richards and S. Boyer. J. Amer. Chem. Soc., 1921, 43, 274—294.

The single electrode potential of gallium is no easily reproducible, and has a maximum value o −0·30 volt in $N/10$ solution. Gallium is purified b electrolysis, followed by ignition in a high vacuu or by recrystallisation to remove traces of zinc. I melts at 29·75° C., and the solid has sp. gr. 5·90 the liquid 6·095, both at the melting point. Th compressibility of the solid is 0·0000020 and of th liquid about twice as large. The coefficient o cubical expansion of the solid is 0·000055, and th sp. gr. at 20° C., 5·907. The latent heat of fusio is 19·04 cals. per g. at 173 megabars pressure. (C. J.C.S. April.)—J. F. S.

Reactions producing magnesium. C. Matignon. Comptes rend., 1921, 172, 381—383.

Three possible processes for the preparation of magnesium are:—

$MgCl_{2sol} + CaC_{2sol} = CaCl_{2sol} + 2\,C_{sol} + Mg_{sol} + 22{\cdot}4$ cals.
$MgO_{sol} + CaC_{2sol} = CaO_{sol} + 2C_{sol} + Mg_{sol} - 8{\cdot}4$ cals.;
$MgO, MgCl_{2sol} + 2CaC_{2sol} = CaO, CaCl_{2sol} + 4C_{sol} + 2Mg_{sol}$ $- 2{\cdot}2$ cals.

These processes can be made to yield magnesium, but the second only proceeded very slowly at 1300° C. with a specimen of calcined dolomite. The first reaction requires the preliminary preparation of anhydrous magnesium chloride, which is a delicate and costly process. Attempts to apply these processes on a semi-industrial scale were not successful. —W. G.

Thermo-electric determination of transition points [of metals]. A. Smits and J. Spuyman. Proc. K. Akad. Wetensch., 1921, 23, 687—690.

When the E.M.F. of a thermocouple is plotted against temperature, a smooth curve is generally obtained, but if one of the metals of the couple has a transition point within the temperature range considered, a discontinuity appears in the curve at the corresponding temperature. This phenomenon affords a rapid and exact method for determining transition temperatures. With an iron-tin thermo-element, the transition point of tin was indicated by a sharp break in the curve at 200·2° C. With a copper-tin thermo-element the transition temperature found was 200·5° C., but in this case the break was less sharp and the result possibly less accurate.—E. H. R.

Thermo-elements. I. Thermal and electrical conductivities of copper-phosphorus alloys. G. Pfleiderer. Ges. Abhandl. Kennt. Kohle, 1919, 4, 401—426. Chem. Zentr., 1921, 92, I., 348—349.

The efficiency of a thermo-element depends in an important degree on the ratio of the thermal to the electrical conductivity. The greater the thermal conductivity in proportion to the electrical, the lower the efficiency. According to the Wiedemann-Franz law, the ratio should be constant, but there are many known exceptions to this rule, and all of them are in the unfavourable direction. Experiments were made with copper-phosphorus alloys prepared from pure electrolytic copper, containing 0·68 to 1·98% P. No deviations from the above law in the favourable direction were found, and it is concluded that there is no hope of increasing the sensitiveness of thermo-elements by decreasing the thermal-electrical conductivity ratio.—E. H. R.

Thermo-elements. II. Thermo-electric force of some antimony-cadmium alloys. F. Fischer and G. Pfleiderer. Ges. Abhandl. Kennt. Kohle, 1919, 4, 440—447. Chem. Zentr., 1921, 92, I., 349.

Alloys of antimony and cadmium in approximately equal atomic proportions show abnormally high thermo-electrical effects against metals or alloys. The effect has been found to be subject to great variations, and is extremely sensitive to heterogeneity in the composition of the alloy. The thermal treatment to which the alloy has been subjected is of great importance. At higher temperatures the thermo-electric force changes not merely as a function of temperature but also on account of permanent changes in the alloy. Amalgamation always lowers the thermal effect. Alloys which have been fused under a LiCl-KCl flux show a specially low effect, which can, however, be raised by subsequent warming without the salt layer.—E. H. R.

Iodine and metals. Matignon. *See* VII.

Patents.

Steel; Production of rustless articles of ——. W. B. Ballantine. E.P. 158,329, 29.10.19.

Non-corrodible or rustless steel is cast around a hot core or ingot of ordinary steel. In the case of tubes rustless steel is cast on the outer and inner surfaces of a hollow cylindrical ingot.—T. H. Bu.

Iron or steel; Pickling ——. British and Foreign Chemical Producers, Ltd. From Rheinische Kampferfabr. Ges. E.P. 158,768, 10.12.19.

To avoid brittleness and the increased tendency of the pickled material to rust there is added to the pickling liquor a small proportion of crude anthracene, sulphite lye, or residues from the production of naphthalene, or a suitable extract thereof, an acid resin, waste acid from the refining of hydrocarbons, or a residue of the distillation of an organic compound.—T. H. Bu.

Iron; Process for the anodic treatment of ——. E. Liebreich. G.P. 328,582, 31.1.19.

The treatment is carried out at high temperatures, and solutions of chromium salts or chromic acid are employed as electrolytes. Bluish-white iron which has been rendered passive in cold nitric acid soon loses its passivity and regains the colour of ordinary iron. Iron rendered passive anodically at higher temperatures shows a white silvery colour which is stable in the air, provided the surface is not exposed to exceptional rust-producing influences. It may even be sand-papered and polished without losing its silvery colour.—J. H. L.

Galvanised iron; Process for reducing the amount of zinc ashes and hard zinc produced in the manufacture of ——. C. Heitmann. G.P. 328,775, 24.10.19.

Iron articles, after removal from the pickling bath and before being galvanised, are subjected to compressed air in a fine stream or streams, whereby loosely adhering pieces of scale or iron are removed and are therefore prevented from rendering the zinc bath impure.—A. R. P.

Selenium and noble metals from electrolytic slimes and the like; Process for recovering ——. M. Chikashige and D. Uno. E.P. 134,536, 28.10.19. Conv., 28.10.18.

The electrolytic slime or other product is fused with lead and suitable alkalis in the form of hydroxide, carbonate, or nitrate, the noble metals being obtained as an alloy with lead and the selenium in combination with the alkali metals. —J. W. D.

Ores and other materials; Leaching and other treatment of ——. E. T. Middlemiss. E.P. 158,320, 29.10 and 19.11.19.

Finely crushed materials are treated with liquor in a series of open cylindrical vessels arranged in a circle, each vessel being inclined at an angle of 45° to the vertical. Each vessel is supported about its longitudinal axis and also by its lower edge when in the inclined position, so that it can be rotated about its longitudinal axis; and is also supported axially about a horizontal shaft so that it can be tilted. Means are also provided for moving the vessels bodily round the circle. By an arrangement of fixed cams the vessels, as they travel round the circle, are automatically raised from their normal angular positions to the vertical for charging, or lowered in the reverse direction for discharging. The crushed material in the vessels is bodily rotated and each particle on exceeding the angle of repose rolls down over the other particles in a spiral path while exposed to the action of the liquor which is more or less quiescent.—J. W. D.

Silver-plating powder. Y. A. F. Schwartz. E.P. 158,460, 6.2.20.

A phosphate of silver, preferably tribasic silver orthophosphate, is mixed with an organic acid soluble in water, preferably tartaric acid, and a chemically indifferent substance, such as kieselguhr. —T. H. Bu.

Metal powders; Manufacture of ——. W. P. Heskett. E.P. 158,740, 21.11.19.

DIFFERENT metals (*e.g.*, Mn 40%, Fe 10% Cu 10%, Al 10%, Sn or Bi 5%, Zn 15%, and Pb or Sb 10%) are subjected to heat so as to melt and alloy them without volatilisation and/or oxidation of any of the metals. The alloyed mass on cooling disintegrates into fine powder.—J. W. D.

Alloy. F. Milliken. Assr. to F. Milliken, S. F. Weaver, and J. M. Repplier. U.S.P. 1,350,166, 17.8.20. Appl., 29.8.18.

AN alloy characterised by a relatively high electrical resistance, elastic limit, tensile strength, and density, a close and fine grain, and a high resistance to corrosion, is composed of copper 50—60, nickel 26—34, iron 4—8, zinc 7—11%, and a purifying agent. The purifying agent preferred is commercial manganese-titanium (Mn 60, Ti 40%) and it is used in such proportion that 0·25—5% remains in the alloy.

Contact points; [Alloy for] electric ——. J. H. Muller. U.S.P. 1,367,752, 8.2.21. Appl., 23.12.18.

CONTACT points for electrical purposes are made of an alloy containing Au 90%, Ni 10%.—C. A. K.

Electrocyanide chlorination process; Machine for ——. R. T. Sill. U.S.P. 1,368,362, 15.2.21. Appl., 16.4.19.

A COMBINATION of a tank, two electrode plates within the tank, one above the other, a hollow column leading upwards from the central part of the space between the electrodes and discharging above the upper electrode, and means for raising liquid pulp through the column.—J. W. D.

Precious metals; Precipitating and recovering —— *from their solutions.* K. B. Moore and H. R. Edmands. U.S.P. 1,368,520, 15.2.21. Appl., 21.9.17.

THE process is continuous and consists in feeding finely ground charcoal through a series of extractor units, through which the metal-bearing solution passes in the opposite direction.—T. H. Bu.

Metallurgical process. [*Chloridising copper ore.*] R. H. Bradford. U.S.P. 1,368,885, 15.2.21. Appl., 18.11.18.

COPPER ore is mixed with a quantity of an alkaline-earth chloride containing sufficient chlorine to combine with the amount of copper present, and the mixture is heated in a non-reducing atmosphere to approximately 800° C. The copper is thus converted into cupric chloride which is volatilised, the fume being collected in the dry state, mixed with an alkaline-earth material and a carbonaceous reducing agent and heated to somewhat above the melting point of copper. Molten copper separates from the chloride slag, which may be re-used in the first part of the process.—T. H. Bu.

Metallic values from ores; Process for obtaining ——. W. A. Schmidt, Assr. to International Precipitation Co. U.S.P. 1,368,973, 15.2.21. Appl., 2.2.20.

THE ore is heated and a metallic chloride is added at successive stages, the temperature being high enough to chloridise the metallic content of the ore and volatilise the resulting chloride.—T. H. Bu.

Ozonisers; Extrapolation and calculation of the concentration and yield of ——. H. Becker. Wiss. Veröffentl. Siemens-Konzern, 1920, 1, 76—106. Chem. Zentr., 1921, 92, II., 253—254.

THE efficiency of an ozoniser is determined by the concentration and yield of ozone obtained when the apparatus is worked under definite conditions of frequency, tension, temperature, humidity of the air or oxygen employed, and velocity of gas in the ozoniser. In order to reduce the time necessary for the determination of the characteristic curves of an ozoniser, showing the relations of the concentration and yield of ozone respectively to the gas velocity, a method whereby the efficiency of the ozoniser at high velocities may be extrapolated from results obtained at low velocities is described. For certain velocities, the expenditure of energy in the ozoniser appears to be constant. A comparison of two ozonisers can be made on their respective expenditure of energy per unit volume of reaction space, which may be termed the wattage density. It is recommended that where alternating current of 500 frequency is available, or where the cost of electrical power is low, the ozoniser should be worked at the highest wattage density possible. Where alternating current of frequency 50 only is available, a small wattage density should be chosen for working the ozoniser. Experiments showed that from 30—35% of the energy supplied to an ozoniser was absorbed by the glass walls of the apparatus. This loss diminished with continued working of the ozoniser. When the wattage density employed exceeded a certain value, the concentration of ozone diminished.

PATENTS.

Crucible furnaces; Electric ——. C. Soncini. E.P. 142,836, 4.5.20. Conv., 25.4.19.

In an electrically heated crucible furnace in which the resistance element is sectional and is composed of granular material, contact is made preferably by means of hollow water-cooled contact pieces, which, by means of a screw, may be caused to exert more or less pressure on the granular filling and so alter the resistance uniformly.—C. A. K.

Electric furnaces. Soc. Metallurgique du Frayol. E.P. 157,051, 22.3.20. Conv., 7.1.20.

In a furnace for melting and refining metals and other substances, the arch, composed of graphite blocks, is capable of upward or downward movement in a water-cooled jacket of steel or cast iron, lining the upper part of the furnace. The electrodes are movable and lateral polar plates connected in parallel with a polar plate at the bottom of the furnace are provided in order to allow of easy starting. When charged cold, the furnace is inclined so that the charge is in contact with the lateral polar plates until the sole becomes heated and sufficiently conductive. On restoring the furnace to normal position, the lateral polar plates emerge from the bath.—C. A. K.

Electric furnace for treating gases. B. Thomas. U.S.P. 1,367,842, 8.2.21. Appl., 30.4.17.

The arcing chamber of an electric furnace for treating gases is provided with a central air inlet at one end and an annular discharge opening at the other end. A number of electrodes bent into the form of a loop enter and leave the chamber through the air inlet. Another electrode is arranged within the annular exit.—J. S. G. T.

Furnaces for the manufacture of electrodes and arc carbons; Collection and utilisation of tar vapours in ——. *Production of a protective coating for electrodes during the process of baking.* F. K. Meiser. G.P. (A) 329,185, 7.1.16, and (B) 329,539, 16.9.19.

(A) Tar vapours are exhausted from the furnace by injector action exerted by the flue gases, and are introduced into the producer used for supplying the gas for firing the furnace. (B) A flux, such as waterglass or common salt, is added to the protective layer (preferably only on the surface), so that it retains its porosity until the temperature at which tar vapours are evolved is attained, and then frits or melts to a dense surface layer.—J. S. G. T.

Electrolytic gas generators [; Separator for ——]. I. H. Levin. E.P. 158,148, 31.12.19.

A separator for use more particularly in the manufacture of pure oxygen and hydrogen by electrolysis comprises a casing partly submerged in the electrolyte and in open communication at the top with the gas space above the electrolyte. A tortuous passage is formed by a partition dividing the casing into two branches communicating at one end. A tubular member open at both ends and extending at one end through the wall of the casing provides communication between the main body of liquid in the cell and the liquid within the casing. The electrolyte flows from one compartment of the cell through the tubular member and tortuous passage, and then either to a duct leading to a fill cup or other storage device, or through an opening in the diaphragm into the other compartment of the cell, and during its flow through the separator is completely freed from gas bubbles.—J. S. G. T.

Electrolytic cell. H. I. Allen, Assr. to Electron Chemical Co. U.S.P. (A) 1,368,010 and (B) 1,368,011, 8.2.21. Appl., 29.4.20.

(A) In an electrolytic cell an anode consisting of parallel spaced bars is enclosed within a basket-shaped cathode formed with perforated corrugations which register with the bars. A porous diaphragm disposed between the anode and cathode bears against the inner faces of the corrugations. (B) A cathode for electrolytic cells consists of a metal plate having a flat marginal flange on all its sides, and provided with parallel corrugations closed at their ends by walls integral with the plate. The end walls and corrugations are perforated, while the flange is non-perforated.—J. S. G. T.

Electric batteries; Primary ——. B. F. S. Baden-Powell. E.P. 158,733, 20.11.19.

Iron and carbon are employed as the respective electrodes in a primary battery in which water is the electrolyte. The carbon electrode may be surrounded by a depolariser, such as a mixture of carbon and manganese dioxide.—J. S. G. T.

Galvanic cells; Exciting medium for use in ——. C. Beyer. G.P. 329,184, 23.4.20.

A mixture of 90% of common salt, 5% of borax, and 5% of hexamethylenetetramine possesses the advantage over ammonium chloride that no crystals are deposited therefrom upon the zinc electrode. —J. S. G. T.

Ozonising substances; Apparatus for ——. A. J. Moisant. U.S.P. 1,368,346, 15.2.21. Appl., 15.3.19.

An apparatus for producing compounds containing ozone, comprises an ozone generator, means for supplying air under pressure thereto, a feeder for the substance to be ozonised, a mixing chamber, conduits connecting the parts and pressure-regulating valves disposed therein.—J. S. G. T.

Ozone generator. E. L. Joseph. U.S.P. 1,368,560, 15.2.21. Appl., 19.7.20.

See E.P. 128,867 of 1919; J., 1919, 644 A.

Electrolysing salt solutions; Apparatus for ——. T. Matsushima. U.S.P. 1,368,955, 15.2.21. Appl., 18.3.18.

See E.P. 114,623 of 1918; J., 1919, 361 A.

XII.—FATS; OILS; WAXES.

Glycerides; Elucidation of the constitution of ——. A. Grün and F. Wittka. Ber., 1921, 54, 273—289.

Attempts to elucidate the constitution of mono- and di-glycerides by a study of the products of their oxidation are described. $\alpha\beta$-Diglycerides would be expected to pass through the aldehydes to the diacylglyceric acids, whilst $\alpha\alpha'$-diglycerides should yield derivatives of dihydroxyacetone. This is shown to occur, to a moderate extent at any rate, and, although it has not been possible to isolate the pure ketone in any instance, its presence can be detected and its amount estimated by Benedikt and Strache's method (treatment with an excess of phenylhydrazine and estimation of the amount of the latter unused by oxidation with Fehling's solution and measurement of the nitrogen evolved). The oxidation method is of no value for distinguish-

ing between α- and β-monoglycerides, owing to the instability of the acyltartronic acids, which should be the primary oxidation products of the latter. The fat is suspended in glacial acetic acid and oxidised at 35° C. with finely divided potassium permanganate, which is added very gradually. A distearin, m.p. 74·5° C. after preservation, prepared from αα'-dichlorohydrin and potassium stearate, proved to be αα'-distearin mixed with a little of the αβ-variety. A second distearin, m.p. 77·5° C., prepared from α-monochlorohydrin and stearyl chloride and subsequent treatment of the product with silver nitrite, was found to consist of almost equal proportions of the αα'- and αβ-isomerides. The progressive hydrolysis of tristearin by sulphuric acid gives a mixture of unchanged tri- and di- and mono-stearins. Oxidation of the distearins of higher and lower melting points shows the presence of the αα' variety in each. (*Cf.* J.C.S., April.)—H. W.

Fats; Interchange of alkyl groups and its relationship to the constitution of ——. A. Grün, F. Wittka, and J. Scholze. Ber., 1921, **54**, 290—299.

Interchange of alkyl groups between a fat and an alcohol can occur in the absence of catalyst at a sufficiently high temperature. Thus, when tristearin is heated with ethyl or isoamyl alcohol at 200° C. or 270° C. in a closed vessel, an equilibrium mixture is ultimately formed containing ethyl or isoamyl stearate, mono-, di-, and tri-stearins, and glycerol, part of the latter, however, suffering decomposition. Similarly, when a well-stirred mixture of ethyl or isoamyl stearate and glycerin is heated in an open vessel at 270°—280° C. (the liberated alcohol is volatilised during the process), stearin and alcohol are formed, and the reaction passes to completion. Even when an excess of glycerol is used, however, the reaction does not follow a simple course, since, owing to peculiar solubility relationships, distearin is alternately formed and decomposed. The anomalies observed in the melting-points of fats are explained on the assumption that they can exhibit co-ordination isomerism, existing as the simple ester form R.CO.OR' and the co-ordination form $R.C{<}\left.\begin{matrix}O\\O\end{matrix}\right\}\cdots R'$. A monoglyceride can thus yield two isomerides, whilst a simple di- or tri-glyceride can exist in three or four forms respectively. This hypothesis is of wider applicability than that recently advanced by Fischer (Ber., 1920, **53**, 1634) which is based on the possibility of slow interchange of alkyl groups at the ordinary temperature and in the absence of a catalyst. (*Cf.* J.C.S., April.)—H. W.

Hydroxystearic acid; A new —— *from hardened castor oil.* H. Thoms and W. Deckert. Ber. deuts. Pharm. Ges., 1921, **31**, 20—26.

By crystallisation of a "hardened" castor oil (m.p. 80° C., iodine value 12) from alcohol a glyceride was isolated which on saponification gave 1.12-hydroxystearic acid, m.p. 83° C. In the hydrogenation of castor oil, therefore, no displacement of the hydroxyl group of ricinoleic acid occurs. On dehydrating the new hydroxystearic acid with boiling 60% sulphuric acid, it yields a mixture of 11.12- and 12.13-iso-oleic acids.—G. F. M.

Rubber seed oil, and a method of producing glycerides from fatty acids. H. A. Gardner. Circ. 118, Paint Manufacturers' Assoc., U.S.A., Feb., 1921. 2 pp.

A sample of rubber-seed oil of iodine value (Hanus) 137 and acid value 57, when mixed with an amount of liquid cobalt drier sufficient to cause raw linseed oil to dry in 6 hrs., yielded a film which was not "set" but was still greasy after several days. On heating 50 g. of the oil with 2 g. of glycerin and 3 g. of calcium resinate to 260° C. for 90 mins., water was given off, and the mixture darkened considerably. The resulting product of acid value 5·1, when mixed with the same quantity of cobalt drier as before, dried overnight to a film similar to that yielded by soya bean oil but inferior to that given by linseed oil. The method of esterifying with glycerin in presence of a catalyst, such as calcium resinate or tungate, may prove of value for improving highly acid oils.—A. de W.

Tung oil heat test; Developments in the ——. H. A. Gardner. Circ. 119, Paint Manufacturers' Assoc., U.S.A., Feb., 1921, 8 pp.

The finding of Jameson (J., 1920, 697 A) that the presence of free fatty acid has an important influence in retarding the gelatinisation of tung oil when examined by the Browne method (J., 1912, 731), as proved by the proportionately shorter time in which gelatinisation takes place after the free acids have been removed by calcium hydroxide, has been confirmed by the author. Jameson's method thus affords a means of determining the purity of samples of tung oil.—A. de W.

Sulphonated oils; Determination of inorganic impurities in ——. R. Hart. J. Amer. Leather Chem. Assoc., 1920, **15**, 404—406.

From the data obtained by the method described previously (J., 1917, 1139), together with determination of the ash, the amount of SO_3 combined as sulphate and of other non-volatile impurities may be readily calculated. Na_2SO_4 (due to combined SO_3) = 0·0634 (A_S+2A), where A_S represents the combined SO_3 expressed in mg. of KOH, and A the alkali minus ammonia similarly expressed. A may be negative in the case of the presence of ammonium salts. The formula holds good only when $2A<A_S$; when $2A>A_S$, A_S is substituted for 2A. Na_2CO_3 = 0·0473(2A − A_S). Salt and impurities = Ash − Na_2SO_4 (due to combined SO_3) − Na_2CO_3. Calculated results agree very closely with actual determinations of Bumcke (*cf.* J., 1919, 831 A).—D. W.

Sulphonated oils; Analysis of ——. *An improvement of the Hart method.* C. G. Bumcke. J. Amer. Leather Chem. Assoc., 1921, **16**, 7. (*Cf.* J., 1917, 1139.)

10 G. of oil is boiled with 25 c.c. of $N/1\ H_2SO_4$ in a 500 c.c. Erlenmeyer flask fitted with a reflux condenser, for 1 hr. over a Bunsen burner. The use of $N/1$ acid in place of $N/2$ obviates the difficulties mentioned by Pickering (J., 1920, 305 T).—D. W.

Soaps; Manufacture of —— *from paraffin wax and similar hydrocarbons.* W. Schrauth and P. Friesenhahn. Chem.-Zeit., 1921, **45**, 177—178.

As substitutes for fatty acids, hydrocarbons such as paraffin have been successfully employed in the manufacture of soap. The constituents were beeswax, 350 kg., paraffin, 300 kg., and ceresin, 300 kg., to which 30 kg. of sodium hydroxide in 100 l. of water was added. The mixture was heated to 160°—180° C., in a steam-heated autoclave, at a pressure of 10 atm., with brisk mechanical agitation, for 8 hrs. A pressure of several atmospheres of air or oxygen is preferably maintained during the process, but the use of catalysts is unnecessary. The use of sodium carbonate, instead of hydroxide, is to be avoided as it gives rise to formation of anhydrides, lactones, or waxy substances, and consequent reduction of detergent properties.
—W. J. W.

Emulsions. II. Reversal of phases by electrolytes, and effect of free fatty acids and alkalis on emulsion equilibrium. S. S. Bhatnagar. Chem. Soc. Trans., 1921, **119**, 61—68.

Trivalent electrolytes are more effective in bringing about the reversal of phases in emulsions than

divalent ones. The difference in the amount of electrolytes required to bring about the reversal with different soaps probably indicates a difference in their protective action, which decreases in the following order:—Potassium stearate, sodium stearate, sodium and potassium palmitates, potassium oleate, and sodium oleate. The reversal of phases in emulsions is affected by dilution in a similar way to the precipitation of colloidal sols. Attributing the cleansing power of soaps to their emulsifying efficiency, it will, on this view, be considerably affected by electrolytic impurities in the water, such as calcium salts. Traces of free fatty acid or of free alkali in emulsions shift the inversion point in opposite directions, and the oil globules are smaller in emulsions containing free alkali.—G. F. M.

PATENTS.

Fats and oils; Process of compounding ——. H. Wade. From Wilson and Co. E.P. 158,175, 17.5.20.

A "HARD" fat such as vegetable or animal stearine is melted with relatively large proportions of fluid oil (*e.g.* 1 pt. of stearine to 3—6 pts. of cottonseed oil, soya bean oil, etc.) and the mixture rapidly cooled during agitation to a temperature slightly above the m.pt. of the stearine present, *e.g.* 106°—115° F. (41°—46° C.). The mixture is then mechanically agitated while being cooled at a very slow rate to a temperature slightly below the temperature of crystallisation of the stearine, *e.g.* about 90° F. (32° C.) to produce a creamy homogeneous non-liquating mass which is then allowed to set. A small proportion of the solid stearine may be added as "starter" to the liquid mixture at or soon after the commencement of the slow cooling operation.—A. de W.

Oil from coconuts; Process of extracting ——. *Process for the separation of food products from fresh coconuts.* W. Alexander, Assr. to The De Laval Separator Co. U.S.P. (A) 1,366,338 and (B) 1,366,339, 25.1.21. Appl., 17.10.18 and 21.5.19.

(A) THE creamy emulsion separated from the liquid expressed from coconut pulp is inoculated with bacteria adapted to digest albumin, and the dry oil separated from the water and albumin sludge. (B) Coconut pulp is subjected to pressure, and the larger part of the water, together with a creamy emulsion consisting mainly of oil, is separated therefrom. The former forms an aqueous flavouring extract, whilst the emulsion is treated to eliminate the greater part of the water and contained albumin.—A. de W.

[Fish] oil; Process for the extraction and refining of ——. P. M. Heyerdahl. U.S.P. 1,368,148, 8.2.21. Appl., 16.7.19.

THE oil is treated below 100° C. with a stream of an inactive gas in the presence of sufficient water to wash the oil.—L. A. C.

Fatty acids; Production of alkali salts of —— *[from petroleum hydrocarbons etc.].* W. Schrauth. G.P. 327,048, 11.11.14.

SUBSTANCES obtained by the chlorination of petroleum fractions, preferably monochloro-derivatives, are subjected to fusion with alkali at 200°—300° C. in such a manner as to avoid a high pressure. The temperature is at first maintained at 200°—230°, and later raised to 300° C. The products obtained after 6—8 hrs. contain dry, odourless soaps, which are soluble in hot water and form an abundant lather. The excess of alkali may be neutralised with hydrochloric acid or fatty acids, or after re-melting it may be extracted by means of steam or water. The hydrogen evolved during the fusion may be utilised technically. Cetyl chloride yields palmitic acid.—J. H. L.

High melting-point fatty acids and neutral substances having an affinity for water; Process for the separation of —— *from the saponification product of wool grease.* I. Lifschütz. G.P. 329,232, 8.6.15.

THE product obtained by saponification of wool-grease according to G.P. 286,244 (J., 1915, 1153) is partly or completely washed and extracted with solvents for the unsaponifiable matter, the residual insoluble soap being treated with acids to separate the fatty acids. The yield of "hard fatty acids" and unsaponifiable matter amounts to about 50% of the wool-wax. The crystals which separate from the solution of the unsaponifiable matter form 15—20% of the total unsaponifiable matter, and consist of wool-grease alcohols of high melting point, which may be used alone or in conjunction with the bulk of the unsaponifiable matter as an artificial wax.—A. de W.

Soap; Manufacture of ——. M. H. Ittner. U.S.P. 1,367,973, 8.2.21. Appl., 8.5.16.

STRONG solutions of soap in dilute lye are subjected when in a thin, freely flowing condition to a continuous centrifugal treatment whereby the separation of settled soap is effected.—A. de W.

Detergent and fulling agent; Process for the preparation of a fat-free ——. E. Gips. G.P. 328,812, 15.9.16.

ANIMAL glue that has been hydrolysed by means of caustic alkalis is combined with fat solvents and saponins. Salts of laminaric acid, sodium or potassium carbonate, or ammonia may also be added. —A. de W.

Glycerin; Process for decolorising liquids containing glycerin or crude ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 144,727, 11.6.20. Conv., 12.2.19.

A CRUDE glycerin solution containing sulphuric acid is treated with oxalic acid, preferably in the form of powder, and then with barium carbonate. The addition of an amount of oxalic acid in excess of that required to precipitate the barium salt increases the bleaching action to such an extent as to avoid in some cases the necessity of adding absorbent decolorising material, *e.g.*, animal charcoal.—A. de W.

Oil; Processes of extracting —— *from fatty substances.* G. D. Rogers. E.P. 147,834, 9.7.20. Conv., 7.3.19.

Interaction of liquid or pulverulent materials. G.P. 302,421. *See* I.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Pigments; Qualitative test for determining the texture of ——. H. A. Gardner and R. E. Coleman. Circ. 117, Paint Manufacturers' Assoc., U.S.A., Feb., 1921. 6 pp.

THE "texture" of a pigment relates to the structure of the particles, and is an important factor in regard to ease of grinding, character of finish, settling and hardening of the paint, and to some extent flowing and spreading power of the paint. To 1—2 g. of the pigment (depending on its oil absorption) placed on a ground-glass plate, is added 1 c.c. of a medium consisting of about equal parts of blown linseed oil (sp. gr. 0·945—0·950) and turpentine, adjusted to a viscosity slightly higher

than that of raw linseed oil. These are mixed to a thin semi-paste with a palette knife, followed by three grinding operations of 1 min. each with a 3″ glass muller, in order to break down agglomerates and thoroughly wet each particle of the pigment. Between each mulling operation a few drops of the medium are added to compensate for evaporation or thickening. The resulting paste is thinned with the medium, transferred to a beaker, and further medium added until a total of 12 c.c. has been employed. After allowing to stand for 1—2 mins. to eliminate air, the mixture is poured on to the upper portion of a clean glass plate held in an almost vertical position in order that it may flow down, and then kept in a vertical position until the film is dry. An examination of the dried film shows the possible presence of larger particles, as well as pieces of lint and dirt in the lower portion of the film. The dispersive power of different liquids varies in degree, some liquids actually possessing the opposite effect of causing agglomeration of the pigment to large hard particles.
—A. de W.

Nitrocellulose solutions for use in lacquers. R. O. Herzog, A. Hildesheimer, and F. Medicus. Z. angew. Chem., 1921, 34, 57—60.

THE nature of the substances which are added to nitrocellulose solutions to produce pliability of the films, has considerable influence on the properties, such as elasticity, extensibility, tenacity, resistance to cold, and water absorption of the product. Investigations have been carried out with many of the agents used for this purpose, including esters of cinnamic acid and salicylic acid, ethyl phthalate, triphenyl and tricresyl phosphates, oils and fats, resorcinol acetate, sulphones, ether, ketones, formanilide, and many combinations of these. By employing two or three of these agents together, certain characteristics may be obtained which are not secured by the use of one substance alone. Thus the brittleness of films, produced by the use of ethyl acetylsalicylate, may be avoided by also adding amyl cinnamate to the nitrocellulose solution. The figures for extensibility, with various additions, are given; they vary between 150% with amyl cinnamate and 25% with amyl salicylate. Ageing of films is sometimes due to solvent retained by the nitrocellulose; but chemical action between the nitrocellulose and the added substances, or changes in the latter, may be contributory causes.
—W. J. W.

PATENTS.

Colours [; Lake ——]. A. Linz, Assr. to Ultro Chemical Corp. U.S.P. 1,358,007, 9.11.20. Appl., 9.9.20.

AN alkali salt of the azo dyestuff from diazotised *p*-nitro-*o*-toluidine and 2-naphthol-3.6-disulphonic acid is dissolved or suspended in water and treated with barium chloride or other compound of a multivalent metal. The scarlet barium lake of the dyestuff is fast to light and insoluble in water, benzene, linseed oil, etc.

Carbon black; Apparatus for the manufacture of ——. H. A. Bubb. U.S.P. 1,367,178, 1.2.21. Appl., 8.5.20.

A BURNER is arranged within and adjacent to one portion of a rotary barrel, and a hood fits in one end of the barrel. A scraper extending into the barrel removes the deposited carbon from the inner surfaces.—A. de W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Vulcanisation; Reactions of accelerators during ——. II. Theory of accelerators based on the formation of polysulphides during vulcanisation. W. Scott and C. W. Bedford. J. Ind. Eng. Chem., 1921, 13, 125—128. (*Cf.* J., 1920, 199 A.)

ORGANIC substances capable of accelerating vulcanisation may be classified into two groups, viz., hydrogen sulphide-polysulphide accelerators and carbosulphhydryl-polysulphide accelerators. The latter class comprises thioureas, dithiocarbamates, thiurams, mercaptans, disulphides, and certain Schiff's bases which during vulcanisation can give rise to thiourea derivatives. The former set includes all basic organic accelerators and such compounds as produce basic accelerators under the conditions of vulcanisation; in vulcanisation, hydrogen sulphide, arising from the action of sulphur on the rubber resins and proteins, combines with the basic accelerator with formation of a hydrosulphide which combines with free sulphur giving a polysulphide, $RNH_2.SH,S_x$; the "polysulphide su

phur" is then transferred in an active form to the rubber. Hydroxides of the alkalis and alkaline-earths also behave in this way; the theory explains their ineffectiveness with deresinised rubbers. Aldehyde-ammonia and *p*-phenylenediamine are purely hydrogen sulphide-polysulphide accelerators; hexamethylenetetramine, on account of the distinct behaviour of some of its decomposition products, can be placed in both groups. Litharge and zinc oxide are described as secondary accelerators, their function being merely to remove hydrogen sulphide from an organic hydrosulphide-polysulphide with consequent liberation of active sulphur and regeneration of the base which is then able once more to form polysulphide; secondary accelerators are not true catalysts.—D. F. T.

Rubber; Action of certain organic accelerators in the vulcanisation of ——. *III.* G. D. Kratz, A. H. Flower, and B. J. Shapiro. J. Ind. Eng. Chem., 1921, **13**, 128—131. (*Cf.* J., 1920, 378 A, 757 A.)

With a mixture of rubber and sulphur the effect of aniline is considerably greater than that of thiocarbanilide, whether comparison be made by means of the physical properties or of the coefficients of vulcanisation. In the presence of zinc oxide, however, both methods of comparison show thiocarbanilide to be more active than aniline. Although in the presence of zinc oxide, the tensile strength of the vulcanised product increases more rapidly with thiocarbanilide than with aniline, the maximum tensile strength is the same for each, and the vulcanisation coefficients corresponding with the maxima are practically identical. The maximum tensile strength for the rubber-sulphur mixture containing aniline is also the same as for the same mixture containing additional zinc oxide, but is attained at a much higher coefficient of vulcanisation. In the presence of zinc oxide, and of either accelerator, particularly of thiocarbanilide, the tensile strength develops in a remarkable manner during the earlier part of vulcanisation while the coefficient is still very low. The activity of aniline and thiocarbanilide appears to be of two distinct types; in the case of the latter a thiocarbamic acid is probably formed, capable of yielding a zinc salt of exceptional effectiveness. With aniline as accelerator, the effect of zinc oxide is manifested almost solely in the physical characteristics of the product, whereas zinc oxide greatly enhances the effect of thiocarbanilide from the point of view both of physical characteristics and chemical combination with sulphur.—D. F. T.

Rubber energy. W. B. Wiegand. J. Ind. Eng. Chem., 1921, **13**, 118—125. (*Cf.* J., 1921, 123 A.)

When rubber is stretched part of the energy is stored as potential energy, part is converted into "reversible" heat and part into frictional heat; on rapid retraction, the potential energy is almost entirely returned as work and the reversible heat is re-absorbed, whilst a further development of frictional heat occurs. The most important energy transformation is that of the conversion of work into frictional heat by hysteresis; the amount of this is found to be considerably increased on increasing the cyclic elongation and to be reduced by an increase in the degree of vulcanisation Comparing various vulcanised rubber samples at a standard cyclic elongation, the hysteresis is found to be increased by the presence of fine mineral compounding ingredients, such as zinc oxide or carbon black, to a greater extent than by moderate changes in the degree of vulcanisation. Whereas a "pure" vulcanised rubber when led through a hysteresis loop to an elongation of 200% degrades approximately 4% of the total energy into heat, the heat formation is 8% in the presence of 5 vols. of zinc oxide per 100 vols. of rubber, and 14% in the presence of 20 vols. of zinc oxide. In a pneumatic tyre cover the fabric contributes to the conversion of energy into frictional heat; the extent of the hysteresis loss from this cause may be determined by an electrical dynamometer or more simply estimated by inserting a 1-in. section of the carcase in the arm of a pendulum which is allowed to commence swinging from a definite position, the oscillation continuing longer the greater the resilience; in this way it is possible to examine the effect of alteration in the number of plies or type of fabric and in the quality and condition of the intervening layers of rubber. Other factors of importance affecting the energy phenomena of compounded rubber are the structure or the method of piling of the compounding ingredients and the surface tension between these and the surrounding rubber. (*Cf.* Schippel, J., 1920, 199 A.)—D. F. T.

Rubber seed oil. Gardner. *See* XII.

PATENTS.

Rubber; Process of devulcanising ——. J. Smith. E.P. 158,783 24.12.19.

The rubber, in a fine state of division, is saturated with a cold solution of the hydroxide or carbonate of an alkali metal and is then heated in a closed receptacle until the internal pressure attains 100 lb. per sq. in. The mixture is then cooled and the soluble alkaline and saline matter removed by washing with water. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 11,159 of 1899, 17,313 of 1904, 2655 of 1905, 29,878 of 1912, and 28,167 of 1913; J., 1899, 773; 1904, 1036; 1905, 934; 1913, 1078; 1914, 876.)—D. F. T.

Rubber; Method of vulcanising ——. F. O. E. Stone. U.S.P. 1,368,071, 8.2.21. Appl., 30.4.20.

The article to be vulcanised is immersed in a molten, easily fusible alloy; the alloy is then solidified by cooling and the embedded article vulcanised by submitting the solid mass to vulcanising conditions; after cooling the mass of metal is again fused by rapid heating, when the vulcanised article can be removed.—D. F. T.

Vulcanised products; Production of soft and elastic ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 328,610, 20.2.17.

Products of great strength and extensibility are obtained by adding to the materials to be vulcanised metallic oxides or peroxides or organic or inorganic compounds which yield part of their oxygen at the temperature of vulcanisation, together with aliphatic or aromatic amines or ammonia compounds or their derivatives or salts. For example, antimony pentoxide, lead oxide, or lead peroxide may be added, together with diethylamine or aniline sulphate.—J. H. L.

Lining tanks with hard rubber. U.S.P. 1,367,231. *See* I.

XV.—LEATHER; BONE; HORN; GLUE.

Chestnut wood; Extraction of ——. C. T. Gayley. J. Amer. Leather Chem. Assoc., 1920, **15**, 344—367.

Experiments were made in a small copper autoclave heated by means of a steam jacket. The usual practice is to extract at a pressure of 2 atm. or more at 266° F. (130° C.). The yield of extract increases with increase of pressure up to 2 atm., but with higher pressures and at temperatures above 250° F. (about 120° C.) the tannin decomposes. The influence of temperature was determined by both the step-up and the constant temperature methods. In

the latter, after each addition of fresh water, the contents of the autoclave are heated to the same temperature, maintained at that temperature for a stated time, and the extract then drawn off. In the step-up method each decoction is carried on for 30 mins. and succeeding decoctions are carried out at temperatures rising 20° for each step. The step-up method of extraction yields a higher percentage of tannin by 5—15% for the same purity of extract. The author recommends this method with a range of 210°—280° F. (99°—138° C.) and 10° rise every time. There is a rapid decrease in the ratio of tans to non-tans extracted with increased time of decoction. The purity of the extract and the yield of tannin are almost uninfluenced by the amount of water used in each decoction. The extract of highest purity, the highest yield of extract, and the greatest speed of extraction are obtained from the finest shredded wood. Beyond a certain limit the increased yield obtained by a greater number of washings is more than counterbalanced by the diminished purity of the extract.—D. W.

"Run" pelts; Investigation of the causes of —— in the sweating process. P. Hampshire. Bull. No. 2, Bureau of Bio-Technology, Leeds. J. Soc. Leather Trades' Chem., 1921, 5, 20—26.

THE examination of "run" pelts damaged in the sweating process has shown the injury to be due to nematodes, organisms of a worm-like character living on organic fluids. The nematodes belong to the family *Nemathelminthes* and are found in all decaying vegetable and animal matter. They do not appear to be present in the skins on arrival at the tannery, but have been found in the sweating chamber itself. The infection arises from material in an advanced state of decomposition, and conditions should be aimed at in the sweating chamber to prevent putrefaction.—D. W.

Acid unhairing [of hides]. R. H. Marriott. J. Soc. Leather Trades' Chem., 1921, 5, 2—9.

VARIOUS pieces of hide and skin were unhaired by means of dilute acids, with or without the addition of neutral salts, and the following conclusions are drawn from the results. The unhairing action is not bacterial and is not so effective as ordinary liming. The hair is not easily removed and the sweat and fat glands are still present in the treated material. Acids have a bating action and skin unhaired by means of acid is softer, when tanned, than a limed and bated skin. The acid liquor appeared to contain unhydrolysed gelatin and a ferment which produced alcohol. Acid unhairing is probably due to the hydrolytic action of the acid on some prosthetic protein similar to mucin, the carbohydrate group being attacked by the ferment. —D. W.

Bating materials; Determination of the tryptic activity of ——. A. W. Thomas. J. Amer. Leather Chem. Assoc., 1920, 15, 221—228.

10 G. of casein is dissolved in 200 c.c. of distilled water and 8 c.c. of $N/1$ NaOH. The mixture is slowly heated to 40° C., and then rapidly to 85°—90° C. to destroy any proteolytic enzyme in the casein. The solution is cooled and made up to 500 c.c. 50 c.c. portions of this casein substrate are transferred each to a 100 c.c. flask, diluted to about 90 c.c., warmed to 40° C. in a thermostat, the enzyme preparation under examination added and the volume made up to 100 c.c. The enzyme action is stopped at stated intervals by pouring the mixture into 25 c.c. of 20% sodium sulphate solution and adding 5 c.c. of $N/2$ HCl. After standing for 1 hr. the undigested casein is filtered off and aliquot portions of the filtrate are used for measuring the proteolysis. One method consists in determining the nitrogen in a portion of the filtrate by the Kjeldahl method, corrections being made for the nitrogen obtained by a blank determination and for the soluble nitrogen introduced with the enzyme preparation. The time of digestion should not be too prolonged since the product of weaker enzymes approaches that of the stronger at the end of 8 hrs. A more convenient and rapid method of measuring the proteolysis consists in titrating 50 c.c. of the filtrate with $N/10$ NaOH, using thymolphthalein as indicator. The amount of alkali required, less that used in a blank test, is an approximate measure of the proteolytic activity. Measurements should be made for the same sample with different times of digestion and compared with similar figures obtained with a standard material. —D. W.

Hide; Swelling of limed and hydrated —— in the presence of acid or alkali. G. D. McLaughlin. J. Amer. Leather Chem. Assoc., 1920, 15, 228—234.

WEIGHED samples of plump, well hydrated, limed hide were soaked for 24 hrs. in equal volumes of solutions of various acids and alkalis of different strengths. With increasing concentration the swelling increased uniformly in the case of "weak" acids, whereas with strong acids it increased to a maximum, after which there was a rapid decrease. Further experiments showed there was no relationship between the concentration of the hydroxyl or hydrogen ions yielded by the dissociation of the various reagents in water and the amount of swelling of the hide. In explanation of the results it is maintained that protein lactate is produced from lactic acid formed in the green hide, sodium chloride proteinate is formed in the salting process and calcium proteinate in the liming process, and that each of these various protein compounds has a definite and characteristic hydration capacity. The increase in weight observed with increasing concentration of acid in the case of "weak" acids is explained by the absorption of the acid itself. —D. W.

Plumping power of solutions [in tanning]; Measurement of the ——. A. A. Claflin. J. Amer. Leather Chem. Assoc., 1920, 15, 234—241.

THE volume of solution filtered from samples of hide powder shaken with different concentrations of acid is approximately constant for a given concentration. 200 c.c. of solution is shaken with 5 g. of hide powder, allowed to stand for 24 hrs., the liquor filtered through cotton cloth without squeezing, allowed to drain completely and the volume of the filtrate measured. The less filtrate obtained the greater the plumping power of the solution. The volumes obtained from 200 c.c. of different solutions are useful for comparative purposes. Lactic acid shows greater plumping power than acetic acid. —D. W.

Sole leather; Laboratory wearing test to determine relative wear resistance of —— at different depths throughout the thickness of a hide. R. W. Hart. U.S. Bureau of Standards. Technol. Paper 166, 21.8.20. 7 pages.

TEST pieces from the same hide were divided into six groups, two of the original thickness of the leather, the others made thinner by skiving off respectively one-third from the grain surface, one-third from the flesh surface, two-thirds from the grain surface, and two-thirds from the flesh side. Preliminary experiments by subjecting these different pieces to the wearing test indicate that the outside surfaces of the leather have much less resistance to wear than the interior portions of the hide. The grain side of the leather has slightly more resistance than the flesh side. (*Cf.* report of British Boot and Shoe and Allied Trades Research Association).—D. W.

Chromium in chrome [tanned] leather; Determination of ——. T. P. Hou. J. Amer. Leather Chem. Assoc., 1920, **15**, 367—374.

In the sodium peroxide method of oxidising chromium solutions, mere boiling is not always sufficient to decompose the excess of sodium peroxide, especially when the volume of solution is large. It is recommended that the solution after oxidation with sodium peroxide should be gently evaporated to a small volume (10—15 c.c.), the evaporation repeated if necessary after addition of water, and the solution then diluted previous to titration. 5—10 c.c. excess of concentrated hydrochloric acid should be present when the solution is titrated. With these precautions the iodometric determination of chromium is rapid, the end point is very sharp, and the method is very accurate. —D. W.

Pyroxylin solvents and "leather solution"; Valuation of ——. J. R. Lorenz. J. Amer. Leather Chem. Assoc., 1919, **14**, 548—566.

The constituents of commercial "leather solutions" or "dopes" used in the production of pyroxylin-coated leather include amyl acetate, ethyl acetate, methyl ethyl ketone, "acetone oils," benzene, solvent naphtha, camphor oil, fusel oil, benzine, methyl and ethyl alcohols, soluble nitrocellulose, oxidised oils, pigments, and varnish gums. Methods for the determination of the various constituents of such mixtures are suggested.—D. W.

Gelatin-hydrochloric acid equilibrium. R. Wintgen and K. Krüger. Kolloid Zeits., 1921, **28**, 81—89.

Gelatin and hydrochloric acid probably react according to the equation $[Ge]NH_2+HCl=[Ge]NH_3Cl$, so that in aqueous solution the equilibrium $[Ge]NH_3Cl+H_2O \rightleftarrows [Ge]NH_3OH+HCl$ exists. The molecular weight of gelatin is 1014 and the hydrolysis constant $4 \cdot 139 \times 10^{-4}$. (*Cf.* J.C.S., April.)—J. F. S.

XVI.—SOILS; FERTILISERS.

Soil moisture; New classification of the ——. G. Bouyoucos. Soil Sci., 1921, **11**, 33—47.

The soil water is divided into gravitational, free, and unfree, the latter being further subdivided into capillarily adsorbed, combined water of solid solution, and combined water of hydration. Of these forms, apart from the gravitational, the free water is that which freezes first at $-1 \cdot 5°$ C., the capillarily-adsorbed water requires a temperature of $-4°$ C. before it freezes, whilst the combined water does not freeze even at $-78°$ C. On the basis of this classification it was found that in some soils only one or two forms of water exist, while in others all three forms exist, but in different proportions. The dilatometer method (Michigan Agric. Exp. Stat., Tech. Bull. 36) is capable of measuring the relative amounts of these various forms of water in the soil. Repeated alternate freezing and thawing causes some of the unfree water to become free, the portion so changing belonging entirely to the capillarily-adsorbed water. Of these various forms of water the gravitational and free water are freely available for the plant; the capillarily-adsorbed water only slightly available, and the combined water not available.—W. G.

Soil solution around the soil particles; Concentration of the ——. G. J. Bouyoucos. Soil Sci., 1921, **11**, 131—138.

Contrary to the generally accepted view, the author believes that the solution around the soil particles and in the very fine capillary spaces is less concentrated than the mass of the solution. In support of this view he presents experimental evidence based on the diminution of the freezing-point depression of soils by successive freezing and thawing, the liberation of unfree (capillarily adsorbed) water from soils by successive freezing and thawing, the abnormally greater increase in the freezing-point depression of soils as the moisture content decreases, and the equality in the freezing-point depression of the supernatant liquid and the soil which it bathes.—W. G.

Soil reaction. I. A résumé. II. Colorimetric determination of the hydrogen ion concentration in soils and aqueous soil extracts. E. A. Fisher. J. Agric. Sci., 1921, **11**, 19—65.

A theoretical paper in which the author criticises the various theories of soil acidity and the methods of determining the same, and in particular points out sources of error in the Hutchinson-McLennan method of determining the lime requirement of a soil (J., 1915, 565). Details of the application to soil extracts of the ordinary colorimetric method of determining hydrogen-ion concentration are given. For the determination of lime requirements of soils increasing amounts of barium hydroxide are added to the soil before making the extract, the hydrogen-ion concentration is determined in each case and a curve plotted. By interpolating at $-\log [H^{\cdot}] = 7 \cdot 07$, and converting barium hydroxide into lime, the lime requirement is obtained. The fineness of division of the soil is an important factor in these determinations of soil acidity.—W. G.

Soils; Occurrence of different kinds of carbonates in certain ——. F. Hardy. J. Agric. Sci., 1921, **11**, 1—18.

The carbonate content of a soil is divided into "calcitoid" and "dolomitoid," the former being soluble in $N/3$ acetic acid at the ordinary temperature and the latter insoluble. Marine silt soils may be expected to contain both forms of carbonate, but soils not directly or indirectly derived from marine silts usually do not contain dolomitoid carbonate. Cultivation for crop production reduces both the calcitoid and dolomitoid carbonate content of soils, but the former disappears much more rapidly than the latter. Soils containing both kinds of carbonate may show a "lime-requirement" as determined by the Hutchinson-McLennan method (J., 1915, 565), although the total carbonate content is apparently well above the usual value taken as indicating deficiency of carbonate. Pure dolomite appears appreciably to retard the whole process of nitrification, although magnesium carbonate only retards the second stage (nitrite to nitrate).—W. G.

Soils; Chemical effect of salts on ——. W. P. Kelley and A. B. Cummins. Soil Sci., 1921, **172**, 139—159.

WITH the two soils examined it was found that chemically equivalent solutions of the chloride, sulphate, and nitrate of a given base produce substantially equivalent chemical reactions. The solubility of the anion of the neutral salt solutions is not materially affected, but an exchange of bases takes place. The salts of the different bases may be arranged in an ascending order of reactivity—calcium, sodium, ammonium, potassium, magnesium. Calcium is the base most readily replaced from the two soils. When phosphates are used, considerable amounts of the phosphate-ion are precipitated by each of these soils. Chemical reactions take place between soils and alkaline solutions, whereby a normal carbonate is converted into a bicarbonate, the hydroxyl-ion concentration of the solution is lowered, and greater amounts of the cation of the solution are precipitated than is the case with neutral solutions. The reactions between neutral salts and soils are dependent on the concentration.—W. G.

Humic acid; Preparation and fractionation of ——. V. A. Beckley. J. Agric. Sci., 1921, **11**, 66—68.

THE soil or other starting material is extracted with 4% aqueous ammonia containing 2% ammonium chloride. The extract is filtered on a collodion filter, any organic matter not dissolving being classed as insoluble humin. The filtrate is acidified and humus is precipitated, Mulder's apocrenic acid remaining in solution. The humus is allowed to dry, and is then extracted with 95% alcohol, which dissolves out Hoppe-Seyler's hymatomelanic acid (Z. physiol. Chem., 1889, **13**, 62). The portion insoluble in alcohol is called humic acid, and is further fractionated by extraction with pyridine, a portion being soluble and the remainder insoluble in this solvent.—W. G.

Humus; Formation of ——. V. A. Beckley. J. Agric. Sci., 1921, **11**, 69—77.

THE formation of humus *in vitro* or in the soil proceeds in two stages. Carbohydrates react with mineral or amino-acids to give hydroxymethylfurfural, which then condenses to form humus. Under laboratory conditions furfural and lævulinic acid are also formed. During the decomposition of cellulose by *Spirochaeta cytophaga* no hydroxymethylfurfural is apparently formed.—W. G.

Sulphur and sulphur composts in relation to plant nutrition. W. E. Tottingham and E. B. Hart. Soil Sci., 1921, **11**, 49—73.

EXPERIMENTS with soil composts having added sulphur or sulphur plus rock phosphate and similar composts with horse manure indicate that sulphur probably functions as a fertiliser both by oxidation to nutrient sulphate and by producing, through oxidation, an acid condition favourable to the production of available phosphate. These processes occur in composts of sulphur and rock phosphate, and probably also continue when the compost materials are incorporated into the soil. The use of sulphur as a fertiliser tends to deplete the soil of lime and phosphoric acid.—W. G.

Sulphur; Inoculated —— *as a plant-food solvent.* J. G. Lipman, A. W. Blair, W. H. Martin, and C. S. Beckwith. Soil Sci., 1921, **11**, 87—92.

EXPERIMENTS with barley and potatoes as crops indicate that sulphur inoculated with micro-organisms capable of oxidising it (*cf.* J., 1916, 1268; 1917, 227) is more effective than uninoculated sulphur for rendering inert mineral plant-food, such as the potash in greensand marl or the phosphate in rock phosphate, accessible to growing crops. Mixtures of inoculated sulphur and ground rock phosphate gave better returns than rock phosphate alone.—W. G.

Iron; Influence of —— *in the form of ferric phosphate and ferrous sulphate upon the growth of wheat in a nutrient solution.* L. H. Jones and J. W. Shive. Soil Sci., 1921, **11**, 93—99.

THE results of a limited number of experiments indicate that iron in the form of ferric phosphate is utilised very slowly and with difficulty by wheat plants. Ferrous sulphate, however, is readily available, but there is an optimum amount above which it is somewhat toxic.—W. G.

Phosphate in soils; Short test for easily soluble ——. O. M. Shedd. Soil Sci., 1921, **11**, 111—122.

THE air-dried soil (10 g.) is shaken for 5 mins. with 25 c.c. of $N/5$ nitric acid, the solution filtered, and the filtrate collected in a standard size test-tube. 1—2 c.c. of a 60% solution of ammonium nitrate and 5 c.c. of ammonium molybdate solution are added and the mixture is heated to 60°C., shaken several times, and allowed to stand for 30 mins. The volume of the precipitate is judged by the eye and classed as "large," "fair," "moderate," "very moderate," etc. The classification with different soils in this manner is in good agreement with the quantitative results obtained after the digestion of the soil with ten times its weight of $N/5$ nitric acid for 5 hrs. Any soil classed as very moderate to moderate or under, that is, containing 0·005—0·0075% or less of soluble phosphorus will probably respond to applications of phosphatic fertilisers.—W. G.

Superphosphate; Determination of citrate-soluble phosphate in ——. P. Müller. Chem.-Zeit., 1921, **45**, 178.

IN the estimation of citrate-soluble phosphate as magnesium ammonium phosphate the results are too low if the precipitate and solution are shaken for ½ hr. and then immediately filtered. It is advisable to let the precipitate stand overnight. In seven tests an average difference of 0·44% was obtained by the two methods.—W. J. W.

Vitamins and auximones; Influence of —— *on vegetable growth.* A. Lumière. Ann. Inst. Past., 1921, **35**, 102—123.

VITAMINS are not necessary for plant growth, for this will take place in culture solutions of known chemical composition free from vitamins. Extracts containing the vitamins in a more or less altered condition may be beneficial to plant growth, but this action cannot be ascribed to the vitamins.
—J. C. D.

PATENTS.

Fertilisers; Manufacture of artificial ——. Akt.-Ges. für Anilin-Fabr. E.P. (A) 146,259, 28.6.20, and (B) 145,582, 29.6.20. Conv., 29.1 and 16.3.18.

(A) A CONCENTRATED solution (85%) of ammonium nitrate, at a temperature not below 70° C., is mixed with potassium chloride, or other inorganic salt with fertilising properties, previously heated to a high temperature, *e.g.*, about 300° C. When reaction has occurred, and the product has hardened through evaporation of water, it is milled; it contains only 1—2% of water. (B) Instead of a hot inorganic salt, a cold salt may be employed, the heat of crystallisation alone sufficing to evaporate the water. Thus potassium sulphate, or a mixture of rock salt and calcined magnesium sulphate, may be added to the ammonium nitrate solution, the latter being at a temperature of 120° C.—W. J. W.

Nitrogenous manures; Manufacture of —— from waste leather and other animal detritus. H. Devos. **E.P. 147,798, 9.7.20.** Conv., 17.12.13.

WASTE leather or similar animal detritus is heated for 1—4 hrs. in a boiler with water containing a small amount of acid, without allowing the liquor to boil. This operation ensures deposition of a gelatinous mass at the bottom of the boiler without decomposition of its nitrogenous constituents. After decantation of the supernatant liquor, the material is allowed to solidify on slabs, and then placed on covered screens where hardening is completed, after which it is pulverised.—W. J. W.

Fertiliser disintegrating and drying apparatus. A. J. Case. E.P. 157,495, 16.8.19.

FERTILISING material mixed with straw and other foreign matter is introduced into an inclined drum formed of perforated plates and capable of being rotated, the interior of the drum having a series of inwardly curving blades. By their action straw and foreign matter are separated from the fertiliser and carried forward to the delivery end of the apparatus, whence they are removed by a conveyor. Finely-divided fertilising material which passes through the holes in the drum falls on to another conveyor. Coarser material is discharged into a trough from which it is elevated to a hopper above a disintegrator, and after passing through the latter it drops on to a table and is mechanically returned to the drum. Drying of the fertiliser is effected by means of a central steam pipe in the drum and a steam-heated plate underneath the disintegrator table.—W. J. W.

Alunite ore; Utilisation of ——. A. Matheson. E.P. 158,293, 28.8.19.

ALUNITE ore containing 4—10% K_2O and 18—38% SO_3 is broken or ground, and heated in a furnace having a series of hearths on which it is mechanically rabbled without admission of air. The sulphurous gases evolved are passed into a retort tower charged with calcined alunite and phosphate rock or bones. Interaction is completed by storing the treated material in open dumps, a potash phosphate fertiliser of any desired composition being produced.—C. I.

Fertiliser; Production of a phosphate —— containing potassium. A. L. Kreiss. U.S.P. 1,366,569, 25.1.21. Appl., 30.7.20.

PHOSPHATE rock is mixed with a rock containing potassium and with more than one alkali metal salt, and the mixture is calcined and leached. —W. J. W.

Fertiliser and process of producing the same. F. S. Washburn, Assr. to American Cyanamid Co. U.S.P. 1,367,846, 8.2.21. Appl., 12.3.20.

PHOSPHATE rock is treated with not more than 10% of sulphuric acid; the phosphoric acid produced is separated from insoluble matter, mixed with sulphuric acid, and the mixture is neutralised with ammonia.—W. J. W.

Fertiliser composition. P. U. Ducommon. U.S.P. 1,368,249, 15.2.21. Appl., 14.7.19.

A BACTERIAL culture is prepared from farmyard manure combined with foods, including pulverised corn (maize) cobs, to retain moisture and sustain bacterial action.—W. J. W.

Ammonium bicarbonate for fertilising purposes; Process for increasing the stability of ——. Badische Anilin u. Soda Fabrik. G.P. (A) 310,055, 11.6.18, and (B) 310,056, 30.6.18.

To prevent or retard separation of ammonia from ammonium bicarbonate it is mixed with (A) 5—10% of anhydrous sodium sulphate or (B) 10% of magnesium sulphate (kieserite).—W. J. W.

Boiling and drying organic substances, particularly offal; Apparatus for ——. K. Niessen. E.P. 137,828, 12.1.20. Conv., 11.5.15.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Loss of —— occurring when sweet-water is used for the slaking of caustic lime. P. Beyersdorfer. Z. Ver. deuts. Zucker-Ind., 1921, 75—87.

LABORATORY experiments lead to the conclusion that when the sweet-water from the washing of the filter-press cake is used for slaking the lime used in clarification, about 5 to 15% of the sugar present in it is destroyed, the actual amount depending principally upon the degree of heat resulting from the hydration, that is, upon the quality of the lime and the proportion in which it is added to the liquid. In practice, where little care may be taken to control the temperature resulting on slaking, the loss may be greater, probably averaging 20%. Caramel does not appear to be formed in any appreciable amount, lactic and acetic acids being the principal products of the decomposition, though benzaldehyde may result if the temperature be unusually high.—J. P. O.

Beet sugar factory; Recovery of the ammonia evolved during clarification in the ——. J. Silhavy. Z. Zuckerind. Czecho-Slov., 1921, **45**, 155—156.

IN the operations of liming with 2% of CaO at 80°—90° C., and carbonating during 6—7 min., only 4·38 kg. of NH_3 or 16·9 kg. of $(NH_4)_2SO_4$ can be recovered in the case of a factory slicing 600 tons of beet per day. Donath's experiments (J., 1920, 379 A) leading to the expectation of a higher yield were carried out under conditions which did not sufficiently correspond to those obtaining in actual practice.—J. P. O.

Sucrose, glucose [dextrose], and fructose [lævulose]; Optical rotation of mixtures of ——. W. C. Vosburgh. J. Amer. Chem. Soc., 1921, **43**, 219—232.

THE specific rotations of mixtures of dextrose and lævulose in equal proportions (invert sugar) in solution are those which the sugars would have if each were present alone at a concentration equal to the total invert sugar concentration. The specific rotations of dextrose and sucrose in mixtures of the two are those which the sugars would have if each were present alone at a concentration equal to the total sugar concentration. The presence of a constant amount of hydrochloric acid of concentration $N/10$, sodium chloride $N/10$, or sodium carbonate $N/25$ has no effect on the determination of the percentage of sucrose when the rotations of the pure sucrose and invert sugar are determined under the same conditions as in the case of the mixtures. (*Cf.* J.C.S., April.)—J. F. S.

Cuprous oxide by reduction [with sugars]. V. V. Sarma. Chem. News, 1921, **122**, 99—100.

THE yellow substance produced by the reduction of an alkaline cupric salt with dextrose is a mixture of cuprous oxide, cuprous hydroxide, and 2—3% of water. A small portion is soluble in ether.

Reduction with sucrose produces only red cuprous hydroxide. (*Cf.* J.C.S., April.)—J. F. S.

Cellobiose [cellose]. Constitution of the disaccharides. V. W. N. Haworth and E. L. Hirst. Chem. Soc. Trans., 1921, **119**, 193—201.

THE complete methylation of cellobiose, first with methyl sulphate and sodium hydroxide and finally with Purdie's reagents (methyl iodide and silver oxide), gave a crystalline heptamethyl-methylcellobioside, m.p. 76°—78° C., n_D=1·4643, which on hydrolysis with 5% hydrochloric acid at 80° C. yielded two products, one, soluble in light petroleum, and identified as tetramethylglucose of the butylene oxide type, and the other, soluble in ether, which was shown to be a trimethylglucose identical with that obtained by the hydrolysis of methylated lactose, and from methylated cellulose. That this trimethylglucose also possesses the butylene oxidic structure was shown by conversion into the above tetramethylglucose by complete methylation to tetramethyl-β-methylglucoside, followed by hydrolysis, and since the free hydroxyl group is the one adjacent to the terminal group, the provisional formula put forward for the constitution of cellobiose (J., 1919, 691 A) in which the two glucose residues are linked together through the reducing group of the one and the hydroxyl group next to the CH_2OH group of the other, is confirmed.
—G. F. M.

Glues; Vegetable —— for wood. E. Stern. J. prakt. Chem., 1920, **101**, 308—327.

THE products of the action of alkali on starch are efficient adhesives, but they gradually suffer coagulation, and it is doubtful whether the difficulty is entirely overcome by preliminary treatment of the starch with acid. Starch viscose (Cross and others, J., 1907, 628) does not coagulate, and experience has shown it to be an efficient substitute for ordinary joiners' glue and to remain unchanged for several months. Joints between wood made by mixtures of the viscose with 0, 5, and 10% respectively of water hardened in 48 hrs. at 13°—18° C., and withstood strains of 47·7, 49·2, and 51·1 kg. per sq. cm., whilst a similar joint made with a mixture of bone glue with 1·5 pts. of water withstood 48 kg. per sq. cm. The paper is largely devoted to a discussion of the chemical nature of starch viscose and of the product of the action of alkali on starch. (*Cf.* J.C.S., April.)—J. K.

Lactose. Adriano. *See* XIXA.

[Sugar] juice; Apparatus for the introduction of —— into vacuum boilers and crystallising vessels. A. Grantzdörffer. G.P. 327,397, 20.8.19.

THE apparatus consists of a substantially rectangular box which has in its long side an outlet slot approximately parallel to the wall of the vessel, so that the juice entering the vessel through the slot causes a circulatory motion of the contents of the vessel.—J. H. L.

Milk-sugar; Manufacture of ——. R. W. Mumford, Assr. to Refining Products Corp. U.S.P. 1,366,822, 25.1.21. Appl., 2.7.17.

IN the manufacture of milk-sugar from clarified and purified whey by evaporation and crystallisation, the liquid is treated with a vegetable carbon which retains the cellular texture of the original material (*cf.* U.S.P. 1,286,187, 1,287,592, and 1,314,204; J., 1919, 129 A, 785 A).—J. H. L.

Starch; Process of modifying ——. E. H. Harvey, Assr. to Perkins Glue Co. U.S.P. 1,366,653, 25.1.21. Appl., 13.5.20.

AN electric current is passed through a conducting bath containing the starch, and the treatment is arrested before the starch has been modified beyond the stage of soluble starch.—J. H. L.

Filters. E.P. 158,387. *See* I.

XVIII.—FERMENTATION INDUSTRIES.

Yeast crops and the factors which determine them. A. Slator. Chem. Soc. Trans., 1921, **119**, 115—131.

IF conditions be so arranged that the limiting factor for the growth of yeast is the amount of sugar in the medium, then the yeast crop will be determined by the way the ratio K/F (K is the constant of growth and F the fermentative activity) varies with different concentrations of sugar, and a diagram can be constructed to show the crops with various initial concentrations of sugar. The method is of general application, and similar diagrams can be constructed when other limiting factors are predominant. The favourable influence of atmospheric oxygen on the crop is to be attributed more to the displacement of carbon dioxide than to a positively favourable influence of oxygen; in fact, free oxygen rather retards the growth in malt wort during the sugar fermentation. The retarding influence of carbon dioxide is much greater, however, and the aeration of the wort lessens the supersaturation by carbon dioxide and larger crops result. There is, however, a second mode of growth such as occurs in lactose yeast water, which is unaccompanied by alcoholic fermentation, and here free oxygen is essential; in the absence of oxygen hardly any growth occurs. The factors determining which mode of growth takes place when both are possible are not clearly defined, but the available nitrogenous food is probably of importance. The influence of temperature on yeast crops is small, the temperature coefficients of K and F being not greatly different from each other. No evidence was forthcoming of the necessity of a vitamin to yeast growth.—G. F. M.

Yeast; Proteins of ——. P. Thomas. Ann. Inst. Past., 1921, **35**, 43—95.

Two proteins have been isolated from yeast. One appears to be a phosphoprotein resembling in some ways caseinogen, and this is termed zymocasein; the other is an albumin, cerevisine. Both proteins have been examined and their products of hydrolysis estimated. Particularly notable is the high percentage of tryptophane present. (*Cf.* J.C.S., April.)—J. C. D.

Pseudomonas polysaccharidarum (n. sp.): an organism which decomposes complex polysaccharides. A. Epstein. Bull. Soc. Bot. Genève, 1920, II. **11**, 191—198. Chem. Zentr., 1921, **92**, I, **224**.

THE new species readily decomposes pectin substances, cellulose, and starch, in presence of air, but does not attack lignin substances. In presence of air it liquefies gelatin within 5 weeks; the resulting liquid is acid and contains amines but not indole.—J. H. L.

Emulsin; Preparation of —— from almonds by different precipitating agents. M. Bridel and R. Arnold. Bull. Soc. Chim. Biol., 1920, **2**, 216—222.

THE properties of the emulsin do not appear to be different when different precipitating agents, such as methyl or ethyl alcohol or acetone, are used, unless contact with the precipitating agent is prolonged.—J. C. D.

Salicinase; Influence of heat on the activity of ——. G. Bertrand and A. Compton. Comptes rend., 1921, **172**, 548—551.

The values of the optimum and maximum temperatures of activity of salicinase vary inversely with the duration of the experiment, but the value of the optimum temperature reaches a minimum of 30° C. for a period of 32 hrs. and prolonging the experiment does not cause any further diminution. The temperature of maximum activity is 70° C. and corresponds with the temperature of instantaneous destruction of the enzyme by heat. —W. G.

Patents.

Lactic acid fermentation; Production of a raw material suitable for —— *from putrefied potatoes.* Knab und Lindenhayn. G.P. 326,548, 16.8.19.

Colloidal constituents of the potatoes, which inhibit fermentation and are difficult to filter, are rendered innocuous by heating, the temperature employed being such that the starch is not gelatinised, *e.g.*, 50°—60° C.—J. H. L.

Yeast; Process for the regeneration of degenerated brewery ——. Nathan-Institut A.-G. G.P. 327,498, 14.9.16.

The yeast is treated with a very dilute solution of alkali or alkaline earth, preferably a 0·05—0·25% solution, at 4°—7° C., and allowed to subside. The testinic acid or testilupin surrounding the cells is thus dissolved without injury to the cells. The yeast may afterwards be strongly aerated for 1 hr. in very dilute wort.—J. H. L.

Alcohol and yeast; Production of —— *from sulphite-cellulose waste liquors.* F. Mizgajski. G.P. 329,111, 24.7.17.

The waste liquors are mixed with molasses and fermented without addition of special yeast food. —J. H. L.

Plastic mass [from yeast]. U.S.P. 1,367,886. *See* XIII.

Worts from vegetables etc. G.P. 326,178. *See* XIXa.

Foodstuffs from yeast. G.P. 328,260. *See* XIXa.

XIXa.—FOODS.

Lactose [in milk]; Volumetric determination of by alkaline potassium permanganate. F. T. Adriano. Philippine J. Sci., 1920, **17**, 213—220.

Twenty-five c.c. of $N/10$ permanganate solution, 25 c.c. of 0·848% sodium carbonate solution, 15 c.c. of water, and 10 c.c. of the lactose solution containing not more than 1·5 g. of the sugar (*e.g.*, milk after treatment with copper sulphate, neutralisation, and filtration) are mixed, heated at 95° C. for 2 mins., 25 c.c of 30% sulphuric acid is then added, and $N/10$ oxalic acid is run in until the liquid is clear. The excess of oxalic acid is titrated with $N/10$ permanganate solution. Reference to a table gives the amount of lactose corresponding with the quantity of permanganate used for the oxidation, this table having been prepared from results obtained with pure lactose. The results obtained are concordant but slightly lower than those yielded by the Soxhlet method.—W. P. S.

Swelling ("solvation") in colloids [gluten, gliadin, barley meal]; Measurement of ——. H. Lüers and M. Schneider. Kolloid. Zeits, 1921, **28**, 1—4.

The swelling of gluten and of its chief constituent, gliadin, in lactic acid solutions has been studied respectively by the gravimetric method by Upson and Calvin (J., 1915, 629) and by the viscosimetric method by Lüers (J., 1920, 449 a). Comparison of the data obtained shows that the two methods give concordant results. The authors have now determined the swelling of barley meal in different aqueous media by the viscosimetric method and by the volumetric method (measurement of the height of a column of the meal after sedimentation in different media), and show that these methods also give concordant results. (*Cf.* J.C.S., March.) —J. F. S.

Hydrocyanic acid in Phaseolus lunatus beans; Quantity of ——. Lührig. Pharm. Zentralh., 1921, **62**, 95—97. (*Cf.* J., 1920, 277 a, 382 a.)

Samples from individual sacks of a truck load (200 sacks) of these beans yielded quantities of hydrocyanic acid varying from 2·3 to 37·7 mg. per 100 g. of beans; average, 20·1 mg. A composite sample from the whole consignment gave 26 mg. per 100 g., hence there is some difficulty in arriving at the true amount present. Beans containing relatively large quantities of the acid may be used for food provided that they are steeped in water for 25 hrs., and that the water in which they are cooked is rejected. There is no evidence that acid ferments (sour milk) produce further quantities of hydrocyanic acid from beans which have been freed from the acid.—W. P. S.

Vitamin B; Effect of alkali on efficiency of ——. T. B. Osborne and C. S. Leavenworth. J. Biol. Chem., 1921, **45**, 423—426.

The instability of this vitamin to alkalis reported by several previous investigators is confirmed. —J. C. D.

Yeast proteins. Thomas. *See* XVIII.

Patents.

Coffee; Manufacture of ——. E. C. R. Marks. From Floyd W. Robison Co. E.P. 157,493, 12.8.19.

Unroasted coffee beans, softened by a limited treatment with water or steam, are subjected to the action of micro-organisms, preferably moulds, for several days, and the action is then arrested by roasting or otherwise. Selected organisms, *e.g.*, *Aspergillus ochraceous*, or others from choice coffee, may be employed, and the beans may be first sterilised to exclude undesired types.—J. H. L.

Fish products and the production thereof. P. B. Jagger. E.P. 157,515, 6.10.19.

Various claims are made relating to the utilisation of cod and other fish; dried food products are prepared from the trimmed heads and other rejected parts, and fodder and manure from other offal. —J. H. L.

Baking powder or self-raising flour. C. S. Brock. E.P. 157,581, 31.10.19 and 18.12.19.

Powdered buttermilk is substituted for a part of the usual acid component of the baking powder or self-raising flour.—J. H. L.

Milk, blood, etc.;] Conversion of dissolved, suspended, or molten substances —— *into the form of a fine powder.* E. Trutzer. G.P. 325,396, 11.6.18.

In the desiccation of liquids, with or without chemical transformation, by atomising in a current of drying gases, the liquid is delivered on to the surface of a horizontal, rapidly rotating cylinder, from which it is thrown off tangentially in a finely divided form.—J. H. L.

Vegetables, vegetable refuse, and the like; Production of extracts or worts from fresh ——. M. Trüstedt. G.P. 326,178, 3.3.18.

The material is subjected for a short time to the action of steam under about 3 atm. pressure, in an autoclave, so that the tissue cells are opened and the juice from the material is cooled rapidly, and gradually released from pressure whilst cooling. In this way the aroma of the material is retained.
—J. H. L.

Yeast; Production of a foodstuff rich in protein from ——. F. Konther. G.P. 328,260, 18.1.18.

Sugar and yeast are introduced into boiling water, and the product is evaporated to dryness and heated to 130° C. or a higher temperature. To avoid evaporation as far as possible, the sugar may be melted with 10—15% of water and mixed with 10—60% of yeast and malt embryos (malt combs), the mass then being dried and heated. The product may be employed for the preparation of jam or beverages, or as a cacao substitute.—J. H. L.

Food preparation from fresh blood; Manufacture of a ——. F. Sgalitzer. E.P. 143,919, 28.5.20. Conv., 15.1.16.

See G.P. 296,925 of 1916; J., 1917, 665.

Viscous liquids [sweetened condensed milk]; Method of treating ——. R. Rafn. U.S.P. 1,368,291, 15.2.21. Appl., 15.10.18.

See E.P. 121,117 of 1918; J., 1919, 596 A.

Semolina; Treatment of ——. A. R. Goodwin. U.S.P. 1,368,792, 15.2.21. Appl., 30.10.18.

XIXb.—WATER PURIFICATION; SANITATION.

Water; Detection of nitrites and nitrates in ——. Escaich. Soc. Pharm. Paris, 7.7.20. Ann. Chim. Analyt., 1921, 3, 56—57.

Fifteen c.c. of the water is treated with 2 c.c. of 10% antipyrine solution and 4 drops of acid mercuric sulphate solution, and a drop of potassium ferricyanide solution is added; a red coloration develops if the water contains as little as 0·1 mg. of nitrites per litre. The test may be applied to the detection of nitrates after these have been reduced to nitrite by means of amalgamated aluminium. If a large amount of chloride is present, the water must be treated with silver nitrate and filtered before the test for nitrites is applied; in testing for nitrates, the treatment with silver nitrate is made after the nitrates have been reduced.—W. P. S.

Hardness [of water]; Soap solutions for determination of ——. A. Krieger. Chem.-Zeit., 1921, 45, 172—173.

For hardness determinations the author recommends the use of soap solution of 10 times the concentration of the usual Clark's solution. The burette should be graduated in degrees of hardness, and a 50 c.c. bottle should be used for the sample.

Filter [; Water ——, *with de-gassing device].* W. Hunold. G.P. 323,720, 6.11.18.

Air is prevented from entering the filter bed along with the feed water by a de-aerating device operated automatically by a float in the supply pipe. The latter is closed at the top and extends down into or below the filtering material, the lower end being open or pierced with holes. A cock suitably disposed in the upper part of the supply pipe permits of the air collected therein being removed. The feed water passes over the float valve, and, becoming thereby atomised, oxidation of iron and similar substances contained in solution in the water is effected by the air collected in the upper part of the supply tube.—J. S. G. T.

Water; Manufacture of agents for removing iron and manganese from, and decolorising and clearing ——. A. Braedt. G.P. 328,630, 5.9.18.

Manganese dioxide is precipitated along with finely divided silicates, or is mixed with the same in a fine state of division and the mixture pressed, dried, and granulated. The hard fragments obtained are very efficient for removing iron and manganese from water.—C. I.

Cellular structures; Method of destroying ——. C. Hering. U.S.P. 1,355,476, 12.10.20. Appl., 27.1.15.

Disruptive changes in cellular structures immersed in a liquid are produced by subjecting the liquid to rapid successive positive and negative pressure changes. A strong vessel is filled with liquid in which the material under treatment is immersed. If this is liquid it is contained in a rubber bag or in a container closed by a rubber membrane. The pressure changes are produced mechanically by means of a plunger or piston. The process may be applied to the destruction of organisms in milk, water, etc., to the treatment of meat to improve its tenderness, to the disintegration of wood for the production of pulp, etc.

Animal and vegetable pests; Material for destruction of ——. R. Haberer und Co. G.P. 329,201, 2.8.18.

The alkaloids and bitter principles derived from leguminous plants are suitable for the destruction of pests. The extract from lupins, on account of the gummy material which it contains, is especially suitable for spraying plants.—W. J. W.

Gas from garbage. U.S.P. 1,367,321. *See* IIa.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine in opium and its preparations; Determination of ——. T. Ugarte. J. Pharm. Chim., 1921, 23, 129—131.

One g. of the opium is heated for 5 mins. on a water bath with 10 c.c. of 67% alcohol, the solution filtered and the extraction repeated three times. The alcoholic extracts are mixed (in the case of tincture of opium the determination is commenced at this stage of the procedure), evaporated, the residue dried at 100° C. for 15 mins., and extracted with four successive quantities (5 c.c.) of cold water. The aqueous extracts are filtered, evaporated, the residue dissolved in 2 c.c. of water saturated previously with morphine, 3 c.c. of $N/1$ ammonia,

also saturated with morphine, is added, and the mixture is shaken with 10 c.c. of ether. After the addition of a further 20 c.c. of ether the mixture is set aside for 30 mins., the crystalline precipitate of morphine then collected, washed with water saturated with morphine, dried at 100° C., and weighed.—W. P. S.

Meconic acid; Synthesis and constitution of ——. H. Thoms and R. Pietrulla. Ber. deuts. Pharm. Ges., 1921, **31**, 4—19.

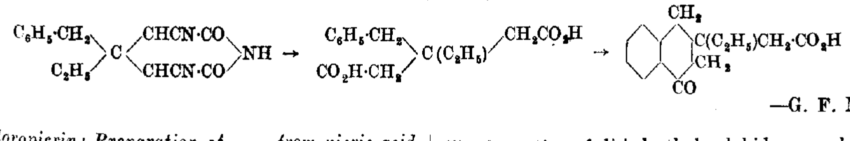
The constitution of meconic acid as 3-hydroxy-γ-pyrone-2.6-dicarboxylic acid, and its close relationship to chelidonic acid, was established by a synthesis of the acid from acetonyldioxalic ester. This substance on bromination in chloroform solution gave a monobromo-substitution product which immediately condensed with loss of water to monobromochelidonic acid (3-bromo-γ-pyrone-2·6-dicarboxylic ester), forming colourless crystals from alcohol, m.p. 68° C. The substitution of hydroxyl for bromine in this compound without far-reaching decomposition presented great difficulty, but eventually a 35% yield of potassium meconate was obtained by the action of a slight excess of 5% potassium hydroxide on an acetone solution of the bromo-ester.—G. F. M.

Humic acids; Constitution of ——. M. Popp. Brennstoff-Chem., 1920, **1**, 58—59.

The classification of humic acids according to Oden (Die Huminsäure, 1919) is given, with the addition of a new product—an acid obtained by P. Brat from peat—to which the name humalic acid is given. Its composition is C 43%, H 6%, O 51%; equivalent weight about 350, and m.p. 168° C. It is soluble in water and alcohol, and all its salts are soluble in water. The solubility of its calcium salt may be important in view of possible applications in medicine—as a substitute for calcium chloride, over which it possesses the advantage that it does not act as an irritant. In alkaline solution it gives a red coloration with ferric chloride, but no precipitate. It behaves as an aldehyde, and has a strongly reducing action.—H. J. H.

Tetrahydronaphthalene; Formation of derivatives of —— from γ-phenyl fatty acids. G. A. R. Kon and A. Stevenson. Chem. Soc. Trans., 1921, **119**, 87—94.

Although γ-phenylbutyric acid itself apparently does not undergo condensation to tetrahydronaphthalene, the ease with which the ring closes seems to be influenced by the character of the groups attached to the β-position of the side chain, and the hydrolysis of the condensation product obtained by Guareschi's method (Atti. R. Accad. Sci. Torino, 1900—1901, **36**, 443) from benzyl ethyl ketone, ethyl cyanoacetate, and ammonia does not give the acid that would have been expected, but the tetrahydronaphthalene derivative formed from it by ring formation, according to the following scheme:—



—G. F. M.

Chloropicrin; Preparation of —— from picric acid and trinitrotoluenes. K. J. P. Orton and P. V. McKie. Chem. Soc. Trans., 1921, **119**, 29—33.

By passing chlorine into a cooled suspension of picric acid (sodium picrate) in aqueous sodium carbonate, a yield of 200% of chloropicrin may be obtained (E.P. 142,878; J., 1920, 527 A); 15—17 equivalents of alkali give the best results. In concentrated sodium hydroxide the yield is much diminished, but with 13 equivalents of sodium hydroxide, of lower concentration than $N/10$, good results may be secured. Low temperature is favourable to the reaction; presence of sodium chloride retards it. By the action of hypochlorite solution on *o*- and *p*-mononitrophenol yields of only 10% and 33—34%, respectively, are obtained. With 2.4-dinitrophenol, 50% is reached. For the preparation of chloropicrin by the action of hypochlorite on trinitrotoluene and T.N.T. residues the best results are obtained by sludging the nitro-compound with water and bleaching powder, the proportions being: nitro-compound, 1 pt.; bleaching powder, 15 pts.; and water, 25 pts. The mixture is gradually heated, and steam is passed through. Grades I. and II. of trinitrotoluene give 82% and 84% yields; T.N.T. residues yield 70%. With dinitrotoluene and *s*-trinitrobenzene 4% and 53%, respectively, are obtained.—W. J. W.

ββ'-Di-iodoethyl sulphide and its application to the detection and estimation of yperite (dichloroethyl sulphide; mustard gas). [Determination of thiodiglycol.] V. Grignard, G. Rivat, and G. Scatchard. Ann. Chim., 1921, **15**, 5—18.

Yperite (ββ'-dichloroethyl sulphide) reacts with hydriodic acid to give ββ'-di-iodoethyl sulphide, m.p. 62° C., and the ready formation of this compound is made the basis of a method for the detection and estimation of yperite. 5 c.c. of 54% hydriodic acid and 15 c.c. of acetic acid are heated for 15 mins. at 70° C. under an air condenser, and the mixture is then cooled and made up to 500 c.c. In 50 c.c. of this solution the iodine is liberated by the addition of 10 c.c. of a 10% solution of sodium nitrite, the iodine is extracted with carbon tetrachloride, and the extract is washed with water and then titrated with $N/10$ thiosulphate, A_0 c.c. being required. A second operation is carried out, about 1 g. of yperite being heated this time with the hydriodic and acetic acids, but before making the volume up to 500 c.c., 100 c.c. of carbon tetrachloride is added. The mixture is vigorously shaken, the two layers are allowed to separate, and from the aqueous layer (400 c.c.) 50 c.c. is taken and titrated with $N/10$ thiosulphate, A_1 c.c. being required. The carbon tetrachloride layer is then carefully separated and the free iodine in it is titrated with $N/10$ thiosulphate, A_2 c.c. being required. Then if the actual weight of yperite taken was P g., the sample contains $(10A_0+8{\cdot}5-8A_1-A_2)0{\cdot}82/P$% of yperite. For the detection of yperite a solution containing 20 g. of sodium iodide, 40 drops of a 7·5% solution of copper sulphate, and 2 c.c. of a 35% solution of gum arabic in 200 c.c. is used. To 4 c.c. of a yperite solution 1 c.c. of this reagent is added and a turbidity is produced after an interval of time varying with the temperature and the concentration of the yperite solution. In this way it is possible to detect 7 pts. of yperite in 1,000,000 of air by bubbling 3—4 l. of air through the reagent.

The formation of di-iodoethyl sulphide may also be made use of in the estimation of thiodiglycol. 0·7—0·8 g. of this substance is weighed out into a 50 c.c. conical flask, 5 c.c. of 54% hydriodic acid is added and the mixture is heated at 70°—75° C. for 15—20 mins. The mixture is cooled, filtered through glass wool, and the precipitate rapidly washed with cold water. In the filtrate the free iodine is esti-

mated by titration with $N/10$ thiosulphate and then the acidity by titration with $N/1$ sodium hydroxide, using phenolphthalein as indicator. If these two titrations give B c.c. and A c.c. respectively, and a blank estimation without any thiodiglycol gives B_0 and A_0 c.c., then the weight of thiodiglycol in the sample weighed out is $61[A_0 - A - (B - B_0)/20]$ mg.—W. G.

Iodoamidines. J. Bougault und P. Robin. Comptes rend., 1921, 172, 452—454.

CONFIRMATION of the view that the iodoamidines are derivatives of hypoiodous acid is given by the fact that iodobenzamidine reacts quantitatively with antipyrine, vanillin, and thymol respectively to give their iodo derivatives. With acetic anhydride it gives a compound, $C_7H_6N_2I_2(CH_3CO)_2O$, which is apparently a derivative of a di-iodo-amidine.—W. G.

Tartaric acid; Decomposition of —— by heat. F. D. Chattaway and F. E. Ray. Chem. Soc. Trans., 1921, 119, 34—37.

IF tartaric acid is heated under reduced pressure so as to effect decomposition at the lowest temperature possible, decomposition takes place in two stages and without any side-reactions. In the first stage only water is liberated, and a residue of the nature of a lactide remains. On further heating, this decomposes into carbon monoxide and dioxide, and formic, acetic, and pyruvic acids. The average amounts of decomposition products from 1 g.-mol. of tartaric acid were: water, 18·8 g.; formic acid, 2·4; acetic acid, 49; pyruvic acid, 14·1; carbon monoxide, 21·3; and carbon dioxide, 43 g.

—W. J. W.

Esterification by zirconium oxide. A. Mailhe and F. de Godon. Bull Soc. Chim., 1921, 29, 101—106.

ZIRCONIUM oxide is a good catalyst for the preparation of esters of aliphatic acids by passing the mixed vapours of the acid and alcohol over the oxide at 270°—290° C. The yield of ester depends on the weight of oxide used, the velocity of flow of the vapours, and the proportion of acid to alcohol.

—W. G.

Alcohols; Dehydrogenation of —— by catalytic oxidation. C. Moureu and G. Mignonac. Bull. Soc. Chim., 1921, 29, 88—101.

A DETAILED account of work already published (*cf.* J., 1920, 247 A, 764 A).—W. G.

Amines; New method of preparation of secondary —— and attempts to alkylate these bases. A. Mailhe. Bull. Soc. Chim., 1921, 29, 106—110.

A DETAILED account of work already published (*cf.* J., 1921, 194 A).—W. G.

Organic compounds; Method of determining and verifying the purity of —— by oxidation with chromic acid. H. Cordebard. Ann. Chim. Analyt., 1921, 3, 49—53.

OXIDATION by heating with an excess of standard bichromate solution and sulphuric acid (as in the method for the determination of glycerol) and subsequent titration of the excess of bichromate with ammonium ferrous sulphate solution affords a means of determining the quantity or purity of a considerable variety of organic compounds.

—W. P. S.

Cineol; The cresineol method for the determination of ——. C. E. Sage and J. D. Kettle. Perf. Essent. Oil Rec., 1921, 12, 44—46.

FOR the determination of cineol in eucalyptus oils, the cresineol method (J., 1920 A, 610 A) yields slightly higher figures than does the phosphoric acid method. When the cineol phosphate is weighed, the factor 0·588 should be used in calculating the amount of cineol present, and not the theoretical factor 0·611.—W. P. S.

Cineol; The cresineol method for the determination of ——. T. T. Cocking. Perf. Essent. Oil Rec., 1921, 12, 44.

IT is pointed out that as long as the phosphoric acid method of determining cineol is official, an oil which gives 55% of cineol as determined by the cresineol method (J., 1920, 610 A) will not conform to the requirements of the British Pharmacopœia.

PATENTS.

Anæsthetic compounds. O. Kamm, R. Adams, and E. H. Volwiler, Assrs. to The Abbott Laboratories. U.S.P. (A) 1,358,750 and (B) 1,358,751 16.11.20. Appl., 23.1.20.

(A) THE di-*n*-butylaminoalkyl esters of aromatic acids, of the general formula, $Ar.CO.O.(CH_2)_x NR$ (Ar is an aryl group containing a benzene nucleus and R is an *n*-butyl group), are obtained by the interaction of benzoyl chloride or a substitution product and di-*n*-butylaminoethyl alcohol. The latter, which has not previously been described, is prepared by the interaction of ethylenechlorhydrin and di-*n*-butylamine; it boils at 225°—230° C. with slight decomposition. The hydrochlorides of the β-di-*n*-butylaminoethyl and γ-di-*n*-butylaminopropyl esters of *p*-aminobenzoic acid melt at 170°—172° and 104°—105° C. respectively. (B) The γ-dialkylamino-*n*-propyl esters of aromatic acids of the general formula, $Ar.CO.O.(CH_2)_3.NR'R''$ (Ar is an aryl group containing a benzene nucleus and R' and R'' are alkyl groups, one of which is larger than an ethyl group), are prepared by the interaction of benzoyl chloride or a substitution product and γ-dialkylaminopropyl alcohol. γ-Di-*n*-butylaminopropyl alcohol, b.p. 235°—240° C. (slight decomp.), 170° C. at 80 mm., is obtained by the interaction of trimethylenechlorhydrin and di-*n*-butylamine. The hydrochlorides of the γ-di-*n*-butylaminopropyl, di-isobutylaminopropyl, di-isoamylaminopropyl, and di-isopropylaminopropyl esters of *p*-aminobenzoic acid melt at 104°—105°, 169°—169°—170°, and 178°—179° C. respectively.

Urea; Manufacture of —— from cyanamide with the aid of solid catalysts. Akt.-Ges. für Stickstoffdünger. G.P. 301,263, 25.3.16.

REDUCING substances which would contaminate the catalysts are eliminated or rendered harmless before the reaction. The reducing substances are chiefly sulphur compounds coming from the crude calcium cyanamide and from the gases containing carbon dioxide used in preparing the cyanamide solution. Permanganates, persulphates and hydrogen peroxide may be used for the removal of the reducing substances.—C. A. C.

Rhamnus carneolica; Manufacture of an extract from the bark of —— for therapeutical purposes. Saccharin-Fabr. A.-G. vorm. Fahlberg, List und Co. G.P. 328,767, 25.8.18.

THE drug is heated with steam in an autoclave to 140° C., and the soluble substances are then extracted. By heating to 140° C. the therapeutically inactive substances insoluble in water and alcohol are hydrolysed and converted into soluble, active substances. The extract is milder and more efficacious than that prepared at 100° C.—C. A. C.

Acetic anhydride; Process of making ——. H. Dreyfus. U.S.P. 1,368,789, 15.2.21. Appl., 26.12.17.

SEE F.P. 478,951 of 1914; J., 1916, 1179.

Non-flammable liquid. E.P. 158,494. *See* I.

Condensation products of naphthalene and its derivatives. G.P. 301,713. *See* III.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Photographic plate; Action of light on the ——. *II. The under-exposure period.* G. I. Higson. Phot. J., 1921, **61**, 144—152.

IN extending the application of the equations previously given (J., 1921, 27 A, 99 A) to the under-exposure period of a plate characteristic curve it is deduced that films may be regarded as one grain in thickness. It is suggested that for most plates, and for exposures of over $\frac{1}{150}$ sec. to white light, density in the under-exposure region is proportional to the square of the light intensity (for intensity scale exposures). The DI (density-intensity) curve has a point of inflexion and the intercept on the I axis of the tangent at this point, λ, is regarded as a constant of the plate; λ represents the speed of the plate for very short exposures. Conclusions as to "cut" are also deduced which are not quite in agreement with Renwick's conclusions (Phot. J., 1913, **53**, 127). The ratio between inertia (i) and λ is constant and equals 1·71; also for any one plate and under such conditions that DaI^2, the ratio between u (the slope of the above tangent) and γ (development factor) is proportional to the speed of the plate. Experimental details of the determination of λ are given and also some conclusions with respect to time-scale exposures in the under-exposure region.—B. V. S.

Photographic plate; Blackening of a —— *as a function of intensity of light and time of exposure.* P. S. Helmick. Phys. Rev., 1921, **17**, 135—146.

PLATES, specially coated on plate glass, were exposed for varying times, or at varying distances, in monochromatic light obtained by a Hilger Monochromatic Illuminator. Three types of plate and three wave-lengths of light were used. Plates were developed in a quinol developer for a standard time, a correction to this being applied for variation in temperature. A mathematical and a graphic method are given for evaluation of the constants in the equation relating density of image to exposure given. The methods outlined are used for calibrating plates which may subsequently be used for the photographic determination of light intensities. The conclusions of Kron and Lemon that Schwarzschild's constant p, in the equation $It^p=C$ for equal density, varies with I, are confirmed and experimental values of p are given varying from 0·68 to 1·95.—B. V. S.

Photographic research; Some new directions for ——. J. Rheinberg. Phot. J., 1921, **61**, 120—125.

THE author draws attention to the scope for research in a study of the alteration of the physical properties of colloids by the action of light and illustrates it by some recent processes dependent upon such alterations. To obtain a multicolour screen for a process of colour photography a collodion film is coated with a resist film containing green ferric ammonium citrate and uranium nitrate. The film is exposed behind a line screen, the exposed parts becoming permeable to acidified alcohol by means of which dyes may be extracted from or introduced into the collodion film underlying the exposed parts. Gum arabic, fish-glue, and albumin may be used for the resist film; the process may be repeated by removing the film and recoating in the case of the two former, or by washing out the soluble salts and re-sensitising in the case of the albumin. In a process for the manufacture of graticules the resist film, of collodion, fish-glue, gum arabic or albumin, containing an iron salt and sensitised by alcoholic solution of silver nitrate, is rendered more permeable to hydrofluoric acid gas by exposure to light. Reference is also made to the fact that the tendency of collodion films to dry with a wavy surface is due to the very different rates of evaporation of the ether and spirit used as solvents, and can be overcome by replacing these by methyl alcohol.—B. V. S.

Latent [photographic] image; Theory of the development of the ——. M. Volmer. Z. wiss. Phot., 1921, **20**, 189—198.

CAREFULLY prepared finely-divided silver was obtained by reduction of silver nitrate by formaldehyde. It was found that the presence of a small quantity of this in a solution of a developer increased the rate of oxidation when air was bubbled through the solution. The results are given for catechol, metol, quinol, glycin, *p*-aminophenol, amidol, and eikonogen, the effect being most marked with *p*-aminophenol and least with metol and eikonogen. Similar results were obtained with *p*-aminophenol and metallic gold and platinum, but no acceleration of oxidation was produced by glass powder, silver sand, or barium sulphate. The possible connexion between the catalytic effect of metallic silver in this experiment and ordinary development processes is discussed.—B. V. S.

[Photographic] development; White light ——. B. V. Storr. Phot. J., 1921 **61**, 126—128.

A SHORT account is given of the work of Lüppo-Cramer which has resulted in the process by which plates may be developed in white light after a preliminary treatment with a weak solution of certain dyes, chiefly those of the safranine class (J., 1921, 28 A, 99 A.)—B. V. S.

Persulphate [photographic] reducer; Irregularities in the action of ——. A. and L. Lumière and A. Seyewetz. Brit. J. Phot., 1921, **68**, 124—125. Phot. J., 1921, **61**, 144.

THE chief cause of irregularity in the reducing action of persulphate is variation in acidity. The explanation previously advanced by Sheppard (J., 1918, 607 A) attributing the variation to variable iron content is shown to be insufficient, as active solutions have been made quite free from iron. The presence of chloride, either in the persulphate or in the tap-water used for dissolving it, may also produce irregularities, since 0·04 g. of sodium chloride per 100 c.c. of 4% persulphate solution completely inhibits the solvent action if the solution is only slightly acid; larger quantities of chloride lead to bleaching or to slight intensification due to change of colour if the acidity is increased also. Sulphates and nitrates have a slight retarding effect in slightly acid solutions which is overcome by increasing the acidity. Chemical reducers, such as thiosulphate left in the film by insufficient washing, reduce the persulphate and prevent its effect on the silver image.—B. V. S.

Colloid chemistry and photography. LI. Staining as a reagent for [extent of] surface. Lüppo-Cramer. Kolloid Zeits., 1921, **28**, 90—93.

CONSIDERATION of the relative colour-sensitising capacities of silver haloid salts (iodide, bromide, and chloride) and their relative staining powers with various dyes, along with other similar factors,

e.g., the observed disintegration of silver bromide grains on conversion to iodide, leads to the general conclusion that the effective surface of the grains is much more important in determining degree of adsorption of dyes than is the purely chemical nature of the halide.—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Explosives; Some properties of ——. R. Robertson. Chem. Soc. Trans., 1921, **119**, 1—29.

WITH nitro-derivatives of the benzene series, the lowest heat of formation is found when the nitro-groups are adjacent; in such cases stability is lower, and the sensitiveness to impact increases. Thus 1.2.4-trinitrobenzene and 2.3.4-trinitrotoluene are inferior to their respective 1.3.5- and 2.4.6-isomerides. The heats of explosion of various explosives were determined by detonating them in a steel envelope at a loading density of 1·3; in this way trinitrotoluene gave 924, and picric acid 914 cals., as compared with 641 and 793 found by Poppenberg. The heat of explosion of dinitrobenzene is 820; this substance was used, without admixture, as a high explosive for shells during the war. In connexion with the decomposition of explosives at even low temperatures, many temperature coefficients have been determined; with nitroglycerin quantitative results have been obtained down to 60° C. The decreasing resistance to decomposition of a series of explosives was found to correspond to the ease with which they can be hydrolysed. With aromatic nitro-compounds, a measurable evolution of gas is only reached with the trinitro-derivative. Rate of detonation of explosives appears to fall in line with their heat of explosion and is therefore dependent on their molecular structure. In regard to amatols, their sensitiveness is not increased by heating, but is appreciably increased by presence of grit and of certain salts. The rate of detonation of trinitrotoluene is not much reduced by admixture with ammonium nitrate up to 40%, the respective figures being 6950 m.p.s. for trinitrotoluene (d. 1·57), and 6470 m.p.s. for 40/60 amatol; 80/20 amatol gives 4620 and 5080 m.p.s. for densities of 1·3 and 1·5 respectively; and this rate is not appreciably altered by varying the thickness of the container wall. (*Cf.* J., 1921, 26—27 R.)—W. J. W.

Trinitrotolylmethylnitroamine [; *Preparation of* —— *from trinitrotoluenes*]. O. L. Brady and W. H. Gibson. Chem. Soc. Trans., 1921, **119**, 98—104.

BY treatment of 2.3.4-trinitrotoluene in alcoholic solution with methylamine hydrochloride and ammonia solution, 2.4-dinitromethyl-*m*-toluidine is produced; 4.6-dinitromethyl-*m*-toluidine is similarly prepared from 3.4.6-trinitrotoluene. With dimethylamine hydrochloride, 2.4- and 4.6-dinitrodimethyl-*m*-toluidines are formed. For the preparation of 2.4.6-trinitrotolymethylnitroamine, 2.4- or 4.6-dinitromethyl- or dimethyl-*m*-toluidines, or a mixture of these obtained by the action of methylamine hydrochloride containing dimethylamine on a mixture of 2.3.4- and 3.4.6-trinitrotoluenes, is introduced into nitric acid (sp. gr. 1·5), warmed to 50° C., and the mixture is heated on a water-bath till evolution of nitrous fumes ceases, after which it is cooled and water added, the trinitrotolylmethylnitroamine separating out as an oil which solidifies on standing. The solid is recrystallised from alcohol containing a few drops of acetic acid, or from a mixture of alcohol and benzene. Other compounds of which the preparation is described are: 2.4- and 4.6-dinitrotolylmethylnitroamine, 2.4.6-trinitrotolylmethylnitrosoamine, 2.4- and 4.6-dinitrotolylmethylnitrosoamine and 2.4.6-trinitromethyl-*m*-toluidine. —W. J. W.

Chloropicrin. Orton and McKie. *See* XX.

PATENTS.

Nitrocellulose powder; Coated —— *and process of making the same.* R. G. Woodbridge, jun., Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,354,640, 5.10.20. Appl., 20.2.20.

NITROCELLULOSE powder (100 pts.) is mixed with about 2 pts. of a non-volatile solvent, *e.g.*, dinitrotoluene, in a revolving drum, 1—10 pts. of black powder is added, and agitation is continued at a temperature slightly above the melting point of the dinitrotoluene, so as to obtain nitrocellulose powder, the grains of which have a firmly adherent coating of black powder.

Potassium chlorate; Form of —— *and process of producing the same.* E. R. Wolcott, Assr. to International Precipitation Co. U.S.P. 1,355,203, 12.10.20. Appl., 17.3.19.

POTASSIUM chlorate in the form of silky or fibrous crystals, specially suitable for use in explosives, as they are less liable than the ordinary form to produce explosions on grinding with easily combustible substances, is obtained by boiling a saturated solution of potassium chlorate with an aqueous solution of the tarry product formed by treating Californian crude petroleum with oleum, which is probably composed of sulphonated products of unsaturated hydrocarbons; after boiling, the mixture is filtered and the solution allowed to crystallise.

Screens [*used in nitrocellulose manufacture*]; *Process of cleaning* ——. R. G. Woodbridge, jun., Assr. to E. I. du Pont de Nemours and Co. U.S.P. 1,367,111, 1.2.21. Appl., 31.5.17.

METALLIC screens through which nitrocellulose has been passed are cleansed by the application of an alkaline salt solution, the action being controlled by regulation of temperature and concentration. —W. J. W.

Explosive powder. A. Langmeier, Assr. to Hercules Powder Co. U.S.P. 1,367,608, 8.2.21. Appl., 27.3.20.

AN explosive consists of trinitrotoluene mixed with ammonium perchlorate and sodium nitrate, these salts being first coated with trinitrotoluene. —W. J. W.

Match-heads; Composition for ——. W. A. Fairburn, Assr. to The Diamond Match Co. Reissue 15,039, 15.2.21, of U.S.P. 1,360,283, 30.11.20. Appl., 3.1.21.

SEE J., 1921, 101 A.

XXIII.—ANALYSIS.

Anemometer; A new ——. H. Gerdien and R. Holm. Wiss. Veröffentl. Siemens-Konzern, 1920, **1**, 107—121. Chem. Zentr., 1921, **92**, II., 251—253.

THE anemometer is constituted of a Wheatstone bridge, two arms of which are formed of very thin wires of high temperature coefficient, heated by an electric current and inserted directly behind one another in the stream. The leading wire is cooled by the stream to a greater extent than the second, and the galvanometer deflection thereby produced serves to indicate the magnitude of the velocity of the stream (*cf.* J., 1918, 167 T; 1920,

803 A). The apparatus is applicable to the measurement of the velocities of gases in pipes. If an obstruction is placed in the pipe, with one arm of the anemometer on either side of it, measurements of large velocities may be made. The only important correction necessary to the indications of the instrument is that due to alteration of temperature of the gas. The necessary correction can be calculated or mechanically compensated, the latter method eliminating any necessary correction to within 0·1% per degree centigrade. The device can also be employed for the measurement of high velocities by by-passing a constant fraction of the stream over the heated wires. The temperature of the wires is much below that necessary to cause corrosion of the wires due to combustion of dust or to cause ignition of explosive gaseous mixtures. Impurities in the gas influence the readings of the instrument. Thus 1% of illuminating gas admixed with air reduces the sensitiveness of the instrument by about 3·5%.—J. S. G. T.

Chlorine and bromine ions; Detection of —— in the presence of iodine ions. E. Ludwig. Bul. Soc. Chim. România, 1920, **2**, 23—28.

THE halogens are precipitated from boiling acid solution with silver nitrate, the precipitate being collected and washed free from silver nitrate. It is then boiled with as small an amount as possible of $N/10$ ammonia solution. To a portion of the liquid a little sodium chloride is added. A turbidity indicates chlorides in the original mixture. To another portion of the liquid one drop of a concentrated solution of sodium bromide is added. A turbidity indicates bromides or a trace of chlorides in the original mixture. To confirm the bromides the residue left after treating the precipitate with $N/10$ ammonia is boiled with $N/1$ ammonia solution. The solution obtained is warmed with zinc and an excess of sulphuric acid. When the action is complete the liquid is decanted and tested for bromides by the addition of chlorine water in the presence of chloroform in the usual manner.—W. G.

Acids or bases; Volumetric determination of mixtures of ——, and of polybasic acids or bases. H. T. Tizard and A. R. Boeree. Chem. Soc. Trans., 1921, **119**, 132—142.

MATHEMATICAL expressions are developed to elucidate the conditions which control the accuracy of titration of mixtures of acids or of bases, or of di- or tri-valent acids or bases, which is merely a special case of the former. In a solution containing an equivalent of a weak acid HA, and x equivalents of a weak acid HA_2, the dissociation constants of which are K_1 and K_2 respectively, the indicator suitable for the titration will be conditioned by the hydrion concentration, C_H, at the equivalent point. It is shown that C_H (or C_{OH} in the case of bases) $=\sqrt{xK_1K_2}$, and the condition of titration of the stronger acid (or base) to 1% is that $K_1/xK_2>2{\cdot}5\times10^4$, and for titration to 0·1% $K_1/xK_2>2{\cdot}5\times10^6$. These general conditions can be applied in nearly every case except when solutions are so concentrated that the "neutral salt" effect comes into play. The titration of a single acid or base in presence of water is simply a special case where the second dissociation constant K_2 becomes $K_w \times V$ where V is the dilution and K_w the so-called dissociation constant of water. Here the condition for titration to 1% works out to approximately $K_1=2{\cdot}5\times10^9$. The application of these principles to the titration of ammonia, ammonia and aniline, ammonia and β-picoline, phenol and acetic acid, and acetic and chloroacetic acids is discussed.—G. F. M.

Hydriodic acid; Electro-titration of —— and its use as a standard in oxidimetry. W. S. Hendrixson. J. Amer. Chem. Soc., 1921, **43**, 14—23.

IODIDES may be accurately titrated electrometrically with potassium permanganate in sulphuric acid solution. The reaction is carried out in a three-necked bottle, which carries the burette, a tube for leading in carbon dioxide or air to agitate the solution, and a bright platinum electrode and the connecting tube of a calomel electrode. The EMF of the system is determined as the titration proceeds and the point where there is a sudden rise of EMF is the end point of the reaction. The reaction is affected by the presence of bromides and chlorides, but may be still carried out if the amount of chloride does not exceed that of the iodide and if the bromide concentration is not more than 25% of that of the iodide. Bichromate and iodate in $N/50$ and $N/20$ solutions may be accurately titrated by adding solutions of either to an excess of an iodide in sulphuric acid and titrating the excess by potassium permanganate.
—J. F. S.

Sulphuric acid; Volumetric determination of ——. C. Pezzi. Giorn. Chim. Ind. Appl., 1921, **3**, 10—11.

THE presence of ferric salts, which tenaciously retain occluded benzidine sulphate, renders invalid Raschig's method of estimating sulphuric acid volumetrically by precipitating it as benzidine sulphate and titrating the latter, suspended in water, with $N/10$ sodium hydroxide solution at 50° C. The author finds that results accurate to within about 0·2% may be obtained, even when ferric salts are present, by titration of the precipitated benzidine sulphate with standard sodium nitrite solution. Two g. of benzidine is dissolved in 750 c.c. of water containing 3 c.c. of hydrochloric acid, the solution, when clear, being made up to 1 litre; 0·1 g. H_2SO_4 requires 150 c.c. of this reagent, which is added, in the cold and with continual stirring, to the sulphate solution containing hydrochloric acid. The precipitate is allowed to settle, and the mother-liquor then filtered in small quantities through a double filter-paper on a Buchner funnel; the precipitate is afterwards brought on to the funnel, washed first with the mother-liquor, and finally several times with hot water, using 15 c.c. in all, and then rinsed off the paper into a beaker. The papers are treated in a small beaker with 15 c.c. of concentrated hydrochloric acid until completely destroyed, this solution being added to the suspension of the precipitate, which should be finely divided and quite free from clots. The whole liquid is then titrated with $N/20$ sodium nitrite solution at 10°—12° C. until, even 15 mins. after the titration is complete, a drop of the liquid colours potassium iodide-starch paper; 1 c.c. $N/20$ sodium nitrite is equivalent to 0·002452 g. H_2SO_4.—T. H. P.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

APPLICATIONS.

Bäckström and Cederberg. Apparatus for carrying out highly exothermic catalytic reactions between gases. 8090. Mar. 15.

Bale. Kiln. 9101. Mar. 24.

Ballard. Furnaces. 8846. Mar. 22.

Barber. Means for recovering colloidal matter from liquids. 8809. Mar. 22.

Bouvery and Conort. Self-lubricating anti-friction products. 8534. Mar. 18. (Fr., 26.3.20.)

Broadley. Crushing machines etc. 7623. Mar. 10.

Davis. Evaporators, feed-water heaters, etc. 8572. Mar. 19.

Duffield and Longbottom. Rotary furnaces. 7564. Mar. 9.

Fasting. Process for drying material to be ground in revolving drums. 8023. Mar. 14. (Denmark, 22.3.20.)

Fooks. 7664. *See* II.

Gensecke, and Metallbank u. Metallurgische Ges. Utilisation of waste heat. 7886. Mar. 12.

Henshilwood and Wood. Non-conducting material for steam boilers etc. 8027. Mar. 15.

Heylandt Ges., and Unruh. Cooling and liquefying air etc. 7818. Mar. 11. (Ger., 28.7.20.)

Mason. 8324. *See* II.

Mauss. Heat treatment of liquid. 7454. Mar. 8.

Mauss. Treating liquids with gases. 7455. Mar. 8.

Mauss. Vacuum separation of colloidal matter from liquid mixtures. 7457. Mar. 8.

Mauss. Centrifugal decanters. 7458. Mar. 8.

Petsch and Still. Distillation columns. 8150. Mar. 15.

Petzel. Bodies for filling columns, towers, etc. through which gas is passed in an opposite direction to liquid. 8274. Mar. 16. (Switz., 17.3.20.)

Steigner. Kilns. 8303. Mar. 16.

Tesla. Production of high vacua. 9098. Mar. 24.

Torrance, and Torrance and Sons. Grinding-mills. 7770. Mar. 11.

Whitfield. Drying-apparatus. 8966. Mar. 23.

Winzer. Continuous-muffle furnaces or kilns. 8344. Mar. 17.

Withers (Deuts. Evaporator A.-G.). Utilising heat contained in fuel residues of furnaces. 7317. Mar. 7.

COMPLETE SPECIFICATIONS ACCEPTED.

10,174 (1919). Heeley. Distillation furnaces. (159,908.) Mar. 23.

24,721 (1919). British Oxygen Co., and others. *See* X.

26,045 (1919). De Haen Chem. Fabr. List. Method of making filter elements. (134,228.) Mar. 16.

27,466 (1919). Maclachlan, Stewart, and Clark. Boiling-pans and mixing-machines. (159,924.) Mar. 23.

27,522 (1919). Seymour. Pulverising or fine-grinding. (159,925.) Mar. 23.

30,502 (1919). Nitro-Fixation Synd., and Jenkins. *See* X.

31,324 (1919). Imbery. Furnaces. (160,247.) Mar. 31.

1453 (1920). Beyer. Ring furnace and drying plants. (160,328.) Mar. 31.

7648 (1920). Blanch. Separating soluble from insoluble matter. (160,081.) Mar. 23.

16,113 (1920). Elektro-Osmose A.-G. Leaching vegetable, animal, or mineral matter. (145,045.) Mar. 16.

17,759 (1920). Cramm. Grinding or crushing mills. (145,599.) Mar. 23.

20,008 (1920). Balthasar. Jets for evaporating liquids. (147,953.) Mar. 16.

20,078 (1920). Schranz. Concentrating-apparatus for separating substances according to their specific gravity. (148,168.) Mar. 16.

20,631 (1920). Danhardt. Filter for dry-cleaning gases and vapours. (148,800.) Mar. 23.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

APPLICATIONS.

Alexander. Kilns for drying and distilling fuels etc. 8144. Mar. 15.

Bates. Fuel. 8164—8171. Mar. 16.

Corthesy. Extracting gases from hydrocarbons etc. 8269. Mar. 16.

Cutler and Meade. Gas-producers. 9210. Mar. 24.

Davidson. Retorts for distilling coal etc. 8723. Mar. 21.

Ferguson and Highett. Producing and utilising combustible gases for heating. 9177. Mar. 24.

Fooks. Heat-treating bodies in a retort etc. 7664. Mar. 10.

Ginet. Treating bituminous shales. 7557. Mar. 9.

Glover, West, and West's Gas Improvement Co. Settings for vertical retorts. 7568. Mar. 9.

Goold (Universal Oil Products Co.). Cracked petroleum oils and process of producing same. 7747. Mar. 11.

Helps. Gas manufacture. 8631. Mar. 19.

Hird. Apparatus for carbonising coal, shale, etc. 8636. Mar. 21.

Illingworth. Production of smokeless fuels and coke. 9129. Mar. 24.

Kimber and Walker. Destructive distillation of shale etc. 8268. Mar. 16.

McDonald. Manufacture of gas. 7407. Mar. 8. (U.S., 10.3.20.)

Marks (Stephens Engineering Co.). Processes of oxidising fuel. 7897. Mar. 12.

Mason. Retort internally heated by gaseous fuel 8324. Mar. 17.

Morgan, and Thermal Industrial and Chemical Research Co. Treatment of peat etc. 7883 Mar. 12.

Murray. Plant for compressing peat. 7312 Mar. 7.

Murray. Gas-producers using peat. 7313. Mar. 7.

Nesfield. Desulphurising oils. 9157. Mar. 24.

Parrish, and South Metropolitan Gas Co. Utilising spent oxide from gas works etc. 7588. Mar. 9.

Parker. Gas-producers. 8804. Mar. 22.

Paterson, Smith, and Tulloch. Gas-producers. 8220. Mar. 16.

Plauson and Vielle. Manufacture of hydrocarbons from coal etc. 9053. Mar. 24. (Ger., 24.3.20.)

Preston. Recovery of ammonium compounds from coal etc. 7237. Mar. 7.
Rigby. Treatment of peat. 8539. Mar. 19.
Rollason. Manufacture of water-gas. 7248. Mar. 7.
Withers. 7317. *See* I.

Complete Specifications Accepted.

16,364 (1915). Planiawerke A.-G. Arc-lamp electrodes. Mar. 16.
13,638 (1917). Felt. Purification of illuminating and other gases. (159,905.) Mar. 23.
15,756 (1918). Soc. Indus. de Prod. Chimiques. Recovery of ammonia from coke-oven and like gases. (127,549.) Mar. 23.
10,174 (1919). Heeley. *See* I.
24,605 (1919). Holes and Manley. Cracking of hydrocarbon oils. (160,200.) Mar. 31.
24,804 (1919). Gratze. Gas manufacture. (160,202.) Mar. 31.
29,491 (1919). Fleming. Condensing and treating distillates from oil-cracking stills. (159,574.) Mar. 16.
31,074 (1919). Davidson. Preparation of peat fuel for producer or other gas. (159,996.) Mar. 23.
31,138 (1919). Goold (Universal Oil Products Co.). Converting heavy into lighter hydrocarbons. (160,236.) Mar. 31.
31,820 (1919). Dale. Coal and like briquettes. (160,279.) Mar. 31.
1392 (1920). South Metropolitan Gas Co., and Gair. Incandescent gas mantles. (160,040.) Mar. 23.
1550 (1920). Leadbeater. Manufacture of artificial fuel. (160,042.) Mar. 23.
4232 (1920). Bourdon. Gas-purifying apparatus. (139,758.) Mar. 16.
7783 (1920.) Hislop. Fuel. (160,083.) Mar. 23.
10,446 (1920). Jackson (Internat. Gasoline Process Corp.). Apparatus for distilling oils or other fluids. (159,774.) Mar. 16.
16,905 (1920). Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of methane. (146,114.) Mar. 16.
19,202 (1920). Oswald and Brown. Apparatus for extacting oil from oleiferous sandstone shale etc. (160,114.) Mar. 23.

III.—TAR AND TAR PRODUCTS.

Applications.

Adam, Lewcock, Galbraith, and Siderfin. Production of aminophenols etc. 8604. Mar. 19.
Adam, Galbraith, Siderfin, and Tallantyre. Plastic material, and process of preparing same from tar distillates. 8605. Mar. 19.
Benn, Benn, and Benn. Tar distillation etc. stills. 8432. Mar. 18.
Caspari and Warburton. Manufacture of benzene monosulphonic acid. 7830. Mar. 12.

Complete Specifications Accepted.

18,943 (1920). Meister, Lucius, u. Brüning. Manufacture of pyridine bases. (147,000.) Mar. 23.
23,569 (1920). Anderson and Meikle. Treating mineral tars other than coal tar. (159,802.) Mar. 16.

IV.—COLOURING MATTERS AND DYES.

Application.

Imray (Soc. Chem. Ind. Basle). Manufacture of chromiferous complex organic compounds and of chromiferous azo dyestuffs therefrom. 8516. Mar. 18.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

British Cellulose and Chem. Manuf. Co., and Lely. Apparatus for spinning artificial threads etc. 7771. Mar. 11.
Carpmael (Bagley and Sewell Co.). Manufacture of paper. 8282, 8394, 8395. Mar. 16 and 17.
Dreyfus. Manufacture of solutions or preparations having a basis of cellulose derivatives. 8684. Mar. 21.
Dreyfus. Manufacture of products from cellulose derivatives. 8685. Mar. 21.
Fort, Mackenzie, and Robinson. Treatment and purification of yarns and fabrics composed of vegetable fibres. 8069. Mar. 15.
Green. Compositions of cellulose acetate and nitrate. 8348. Mar. 17.
Kershaw and Zdanowich. Manufacture of film-coated fabrics etc. 8968. Mar. 23.
Little, Inc. Cellulose derivative and process of preparing same. 7569. Mar. 9. (U.S., 10.4.20.)
Little, Inc. Preparation of cellulose butyrate. 7570. Mar. 9. (U.S., 26.7.20.)

Complete Specifications Accepted.

9789 (1918). Mayfield. Treatment of silk and other yarns to be worked up into fabrics. (159,907.) Mar. 23.
22,187 (1919). Carlsson and Thall. Reducing the viscosity of solutions of nitrocellulose and its compositions. (136,141.) Mar. 23.
30,219 (1919). Dreyfus. Manufacture of plastic masses. (160,225.) Mar. 31.
1355 (1920). Naefe. Protecting woollen fabrics from moths. (160,039.) Mar. 23.
3342 (1920). Newsprint Reclaiming Corp. Removal of printers' ink from printed matter. (138,628.) Mar. 31.
16,458 (1920). Folien u. Flitterfabr. A.-G. Process for obviating the high inflammability of celluloid. (145,430.) Mar. 16.
18,477 (1920). Jeroch and others. *See* XII.
19,316 (1920). Zellstoff-Fabr. Waldhof, and Schneider. Charging cellulose boilers etc. (147,417.) Mar. 31.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Applications.

Aris. Employment of mordants in dye industry. 9192. Mar. 24.
Burgess, Ledward, and Co., and Harrison. Dyeing acetylcellulose. 8648. Mar. 21.
Fish, Gass, Hammond, and Jackson and Bro., Ltd. Dyeing-apparatus. 9040. Mar. 24.
Hatfield and Restall. Dyeing etc. processes. 7247. Mar. 7.
Lee. Machines for dyeing hanks etc. of yarn. 8591. Mar. 19.
Schofield. Sulphur bleaching of wool fabrics. 7926. Mar. 14.
Taylor. Machines for dyeing and padding or treating fabrics etc. 7367. Mar. 8.

Complete Specifications Accepted.

26,565 (1919) and 17,823 (1920). Petrie and Boardman. Dyeing apparatus. (159,548.) Mar. 16.
26,881 (1919). Calico Printers' Assoc., Ashton, and Nelson. Printing textile fabrics. (159,552.) Mar. 16.
10,429 (1920). Nagelin. Apparatus for treating textiles in hank form by means of circulating liquid. (152,299.) Mar. 23.

16,409 (1920). *Wioland. Dyeing and bleaching apparatus. (146,945.)* Mar. 23.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Benkö. Manufacture of iodine etc. compounds. 9203. Mar. 24. (Hungary, 1.6.20.)

Bloxam (Edwards). Treatment of mineral phosphate. 9171. Mar. 24.

Broadbridge, Edser, and Sellers. Treatment of caliche. 7533. Mar. 9.

Carpmael (Bayer u. Co.). 8393. *See* XIII.

Chem. Fabr. Griesheim-Elektron, and Reitz. Rendering calcium hypochlorite stable. 9025. Mar. 23.

Chem. Fabr. Weissenstein. Process for distilling sulphuric acid. 8988. Mar. 23. (Austria, 21.5.20.)

Duets. Gold- u. Silber-Scheide-Anstalt, and Liebknecht. Generation of hydrocyanic acid. 8147. Mar. 15.

Evans, Parrish, Weight, and South Metropolitan Gas Co. Manufacture of ammonium sulphate. 8515. Mar. 18.

Goldschmidt. Manufacture of magnesium chloride. 7597. Mar. 9. (Norway, 29.3.20.)

Jones and Kelly. Production of alkali pentaborates direct from boron ores. 7879. Mar. 12.

Nitrogen Corp. Production of sodium bicarbonate. 7408. Mar. 8. (U.S., 11.3.20.)

Parrish and others. 7588. *See* II.

Phillipson and Thwaite. Sulphate of ammonia drier and neutraliser. 7754. Mar. 11.

Preston. 7237. *See* II.

Soc. l'Air Liquide. Production of sodium bicarbonate and ammonium chloride. 8133. Mar. 15. (Fr., 17.3.20.)

Complete Specifications Accepted.

15,756 (1918). Soc. Indus. de Prod. Chim. *See* II.

29,293 (1919). New Jersey Zinc Co. Manufacture of zinc oxide. (137,513.) Mar. 16.

29,539 (1919). New Jersey Zinc Co. Production of metal oxides and other compounds of metals. (149,927.) Mar. 16.

29,754 (1919). Reid. Concentration of sea water. (159,592.) Mar. 16.

30,816 (1919). Newall. *See* XI.

30,950 (1919). Collins. *See* X.

32,763 (1919). Loring. *See* XI.

5040 (1920). Kilburn (Norske Akt. f. Elektrokemisk Ind.). Removal of iron from solutions of aluminium sulphate, nitrate, or chloride. (139,470.) Mar. 16.

11,814 (1920). Hauenschild. *See* IX.

16,209 (1920). Badische Anilin u. Soda Fabr. Manufacture of the hydrogen-nitrogen mixture in the synthetic production of ammonia. (145,058.) Mar. 31.

25,423 (1920). Zack. Separation of oxygen and nitrogen. (152,643.) Mar. 16.

VIII.—GLASS; CERAMICS.

Applications.

Arnold and Langwell. Manufacture of glass. 7963. Mar. 14.

Gaved. Recovery of china clay. 7792. Mar. 11.

Marks (Lava Crucible Co. of Pittsburg). Production of ceramic articles. 7402. Mar. 8.

Stubbs. Bleaching earthy materials. 7898. Mar. 12.

Complete Specifications Accepted.

18,283 (1919). Marlow. Gas-fired oven or kiln for making tiles, pottery, etc. (159,522.) Mar. 16.

20,763 (1919) and 5698 (1920). Grace. Drying china clay etc. (159,525.) Mar. 16.

28,886 (1919). Curd. Gas-fired glass-melting furnaces. (159,559.) Mar. 16.

31,877 (1919). Laycock and Laycock. Annealing lehrs or kilns for glass etc. (160,282.) Mar. 31.

2077 (1920). Osmosis Co., Laurie, and Ormandy. Manufacture of refractory articles from china clay. (159,737.) Mar. 16.

12,143 (1920). Dimitri and Delaunay. Refractory and insulating product. (142,512.) Mar. 31.

IX.—BUILDING MATERIALS.

Applications.

Brown and Earle. Mixing and application of slag cement. 9138. Mar. 24.

Merz and McLellan, and Weeks. Cement manufacture. 8408. Mar. 17.

Complete Specifications Accepted.

30,382 (1919). Harden. Acid-proof and insulating materials. (159,956.) Mar. 23.

11,814 (1920). Hauenschild. Burning or calcining cement materials, magnesite, etc. (159,780.) Mar. 16.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Applications.

Ampère Ges., Diegenthäler, and Rothe. Manufacture of molybdenum or its alloys. 7906. Mar. 12. (Ger., 12.3.20.)

Ballantine. Manufacture of ferrochrome alloys. 8334. Mar. 17.

Canning, and Canning and Co. Electroplating apparatus. 7896. Mar. 12.

Coles. Apparatus for sherardising. 7256. Mar. 7.

Craig, Pearson, and Durelco, Ltd. Reduction of oxides of tungsten and molybdenum. 8858. Mar. 22.

Elliott. Manufacture of wrought iron and steel. 7353. Mar. 8.

Franz. Flotation processes of dressing ores. 7451. Mar. 8.

Franz. Destroying froth formed in flotation processes. 7452. Mar. 8.

Franz. Comminuting ores etc. 7453. Mar. 8.

Gillespie. Manufacture of metallic powders. 8705. Mar. 21.

Goskar and Hitch. Compositions for case-hardening iron and steel. 9163. Mar. 24.

Holström and Malmberg. Determination of percentage of carbon in iron and steel. 7797. Mar. 11.

Liebreich. Electrolytic separation of chromium. 7425. Mar. 8. (Ger., 8.3.20.)

Madsen. Electro-deposition of metals. 7297. Mar. 7.

Pacz. Production of alloys. 8529. Mar. 18. (U.S., 18.3.20.)

Pacz. Producing high temperatures and reducing refractory oxides. 8530. Mar. 18. (U.S., 19.3.20.)

Passalacqua. Soldering aluminium. 9207. Mar. 24. (Fr., 11.6.20.)

Pérez. Decomposition of mercury. 7542. Mar. 9.

Perkins. Metallurgy of oxidised iron ores etc. 8524. Mar. 18.

Ramsden, and Shropshire Mines, Ltd. Treatment of ores. 8818. Mar. 22.

Schaufelberg. Anticarbonising paint for case-hardening mild steel and iron. 8977. Mar. 23.

Steen. Granulating and separating moisture from slag. 8994. Mar. 23.

Taylor. Cupola furnaces. 9068. Mar. 24.

Vautin. Treatment of iron ores. 8522. Mar. 18.

Wade (Ballantine). Manufacture of ferro-vanadium alloys. 8523. Mar. 18.
Walter. Alloys. 9116. Mar. 24. (Ger., 24.3.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

5398 (1918). Estelle. Electrolytic production of iron and its alloys. (159,906.) Mar. 23.
24,721 (1919). British Oxygen Co., Bray, and Balfour. Furnaces for subjecting ores etc. to the action of gases etc. (159,530.) Mar. 16.
25,687 (1919). Kjellberg. Treatment of minerals or products containing iron, titanium, and vanadium. (159,532.) Mar. 16.
26,136 (1919). Armstrong, Whitworth, and Co., McGuckin, and Smalley. Copper alloys. (159,537.) Mar. 16.
29,216 and 31,761 (1919) and 1137 (1920). Ballantine. Production of ferrochrome alloys. (159,568.) Mar. 16.
30,502 (1919). Nitro-Fixation Synd., and Jenkins. Manufacture of catalytic iron or catalysts containing catalytic iron. (159,960.) Mar. 23.
30,950 (1919). Collins. Purification of tin or production of tin salts from crude tin. (159,659.) Mar. 16.
10,756 (1920). British Thomson-Houston Co. (General Electric Co.). Tungsten alloy. (160,373.) Mar. 31.
17,388 (1920). Krupp A.-G. Production of low-carbon ferrochromium. (145,709.) Mar. 16.
21,155 (1920). Phillips and Arnold. Solder. (159,797.) Mar. 16.

XI—ELECTRO-CHEMISTRY.

APPLICATIONS.

Canning. 7896. *See* X.
Case. Photo-electric cells. 8943—4. Mar. 23.
Coulson. Accumulators. 7781. Mar. 11.
Darimont. Primary cells. 8256. Mar. 16.
Elektrizitäts A.-G. vorm. Schuckert u. Co. Electrolytic cell. 7973. Mar. 14. (Ger., 14.6.20.)
Liebreich. 7425. *See* X.
Madsen. 7297. *See* X.
Marks (Akt. Kfafveindustri). Heating material in electric furnaces. 9191. Mar. 24.
Plauson. Carrying out electrochemical reactions. 9131–2. Mar. 24.
Vogel. Electric storage cells. 8736. Mar. 21.
Wade (Hazlett Storage Battery Co.). Manufacture of storage batteries. 9024. Mar. 23.

COMPLETE SPECIFICATIONS ACCEPTED.

5398 (1918). Estelle. *See* X.
30,382 (1919). Harden. *See* IX.
30,816 (1919). Newall. Electric furnaces for calcining magnesia etc. (160,231.) Mar. 31.
32,763 (1919). Loring. Electrodes for oxidising nitrogen. (159,709.) Mar. 16.
638 (1920). Allison (Narabayashi). Filling for storage batteries. (160,317.) Mar. 31.
7664 (1920). Marks (Scovill Manuf. Co.). Electric furnaces. (160,082.) Mar. 23.
12,143 (1920). Dimitri and Delaunay. *See* VIII.
12,567 (1920). Allen. Electrodes for storage batteries. (159,782.) Mar. 16.
17,348 (1920). Pechkranz. Electrolysers. (146,184.) Mar. 31.

XII.—FATS; OILS; WAXES.

APPLICATIONS.

Clifford. Soap. 8602. Mar. 19.
Gleitz. Removal of acids from glycerides. 8908. Mar. 23.
Heys and Macpherson. Antiseptic and insecticidal soap etc. 8040. Mar. 15.
Kayser. Recovery of glycerin from soap lyes etc. 8739. Mar. 21.
MacIlwaine. Extraction of oil by volatile solvents. 7713. Mar. 10.
Paley Engineering Co. Manufacture of soap. 8264. Mar. 16. (U.S., 1.4.20.)
Schicht. Manufacture of synthetic waxes. 8409. Mar. 17.
Soc. Anon. l'Oxhydrique Française. Removal of catalysts from oils and fatty bodies treated therewith. 8622. Mar. 19. (Fr., 20.3.20.)
Tseng. Manufacture of transparent soap. 8428. Mar. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

29,705 (1919). Bolton and Lush. Neutralisation of fatty acids in fats and oils. (159,587.) Mar. 16.
1113 (1920). Niessen. Apparatus for treating mixtures of fat and glue water derived from boiling and drying organic substances. (137,842.) Mar. 23.
18,477 (1920). Jeroch, and Reichsausschuss für pflanzliche u. tierische Oele u. Fette. Manufacture of fat from spent sulphite cellulose lyes. (146,430.) Mar. 31.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Boularan. Paint etc. 8513. Mar. 18.
Carpmael (Bayer u. Co.). Manufacture of lithopones and barium hydroxide. 8393. Mar. 17.
Günther. Oil and varnish colours soluble in water. 7286. Mar. 7.
Locke. Coating-materials. 9197. Mar. 24. (U.S., 24.3.20.)
Parker. Water paint. 9057. Mar. 24.
Waele. Inks, pigmenting etc. compositions. 8608. Mar. 19.

COMPLETE SPECIFICATIONS ACCEPTED.

26,426 (1919). Ivinson and Roberts. Composition impervious to oils, spirits, water, etc. (159,542.) Mar. 16.
26,427 (1919). Ivinson and Roberts. Anti-corrosive paint or composition. (159,543.) Mar. 16.
31,392 (1919). Vickers, Ltd., Ioco Rubber and Waterproofing Co., and Nuttall. Condensation of phenolic bodies with aldehydic compounds. (160,258.) Mar. 31.
1814 (1920). Dunham. Production of dry, water-soluble products from karaya gum. (160,045.) Mar. 23.
7489 (1920). Pooley and Stevens. Extraction of gum from grass trees. (160,080.) Mar. 23.
18,079 (1920). Dahl. Apparatus for making white lead. (160,395.) Mar. 31.
28,124 (1920). Fitzgerald. Lithographic inks. (159,809.) Mar. 16.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

APPLICATIONS.

Bilbrough. Manufacture of rubber sponges, paints, solutions, and adhesives, etc. 8355. Mar. 17.
Bouvery and Conort. Recovery of rubber. 8533. Mar. 18. (Fr., 26.3.20.)
Davidson. Preparation of raw rubber. 7563. Mar. 9.
Wheatley. Heat vulcanisation of rubber. 8313. Mar. 17.

COMPLETE SPECIFICATIONS ACCEPTED.

29,930 (1919) and 1691 (1920). Davidson. Manufacture of rubber. (159,602.) Mar. 16.

30,870 (1919). Willard. Devulcanising vulcanised rubber. (159,987.) Mar. 23.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATIONS.

Dobson. Composition for dyeing or colouring leather etc. articles. 9169. Mar. 24.
Jones. Insoluble size. 7716. Mar. 10.
Strain. Manufacture of sheet gelatin. 8071. Mar. 15.

COMPLETE SPECIFICATIONS ACCEPTED.

23,347 (1919). Fairrie. Drying leather etc. by means of gases. (160,197.) Mar. 31.
30,516 (1919). Gilardini. Apparatus for rapid tanning of hides and skins. (160,422.) Mar. 31.
1113 (1920). Niessen. *See* XII.

XVI.—SOILS; FERTILISERS.

APPLICATION.

Roberts. Manufacture of fertilisers. 8732. Mar. 21.

COMPLETE SPECIFICATION ACCEPTED.

6539 (1920). Chemical Construction Co. Apparatus for making superphosphate of lime and similar compounds. (139,803.) Mar. 31.

XVII.—SUGARS; STARCHES; GUMS.

APPLICATIONS.

Acree. Converting wood into sugar etc. 8492. Mar. 18. (U.S., 25.3.20.)
Bloxam (Kantorowicz). Manufacture of starch paste. 8989. Mar. 23.
Bloxam (Kantorowicz). Manufacture of an adhesive from potato starch. 8990. Mar. 23.
Mauss. Treatment of sugar juice. 7456. Mar. 8.

COMPLETE SPECIFICATION ACCEPTED.

30,541 (1919). Grant. Decolorising and purifying sugar. (159,640.) Mar. 16.

XVIII.—FERMENTATION INDUSTRIES.

APPLICATIONS.

Briscoe. Brewing beer etc. 7945. Mar. 14.
Seligman. Vessels for brewing beer etc. 8396. Mar. 17.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Barnes and Hyatt. Purification and clarification of water or treatment of sewage. 7813. Mar. 11.
Daw. Treatment of factory waste etc. 7305. Mar. 7.
Dorr Co. Treatment of sewage. 8275. Mar. 16. (U.S., 31.7.20.)
Dorr Co. Apparatus for treating sewage. 9015. Mar. 23. (U.S., 14.10.20.)
Heys and Macpherson. 8040. *See* XII.
Rothe. Production of a food containing aërobic bacteria. 8800. Mar. 22.
Shields. Foodstuff. 8565. Mar. 19.
Soc. Anon. de Prod. Chim. Etabl. Malétra. Manufacture of a fungicide and insecticide. 7959. Mar. 14. (Fr., 13.3.20.)

COMPLETE SPECIFICATIONS ACCEPTED.

27,401 (1919). Barbet et Fils et Cie. Concentration of fruit juice in the manufacture of grape honey and fruit syrups. (135,175.) Mar. 23.

30,979 (1919). Townsend. Manufacture of mil[k] *food products. (160,284.) Mar. 31.*
8276 (1920). Lombaers. See XX.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Acree. Converting wood into mucic acid etc. 8493. Mar. 18. (U.S., 25.3.20.)
Barrett Co. Manufacture of formaldehyde. 8302. Mar. 16. (U.S., 26.5.20.)
Bloxam (*Chem. Fabr. Griesheim-Elektron*). Manufacture of liquid esters of phosphoric acid. 8825. Mar. 22.
Imray (Soc. Chem. Ind. Basle). 8516. *See* IV.
Mond (Metallbank u. Metallurgische Ges.). Evaporating, concentrating, and drying urea solutions. 8343. Mar. 17.
Thron, and Verein. Chininfabr. Zimmer u. Co. Manufacture of O-alkyl derivatives of hydrocupreine. 8298. Mar. 16.
Wallis. Extraction of thymol. 8485. Mar. 18.

COMPLETE SPECIFICATIONS ACCEPTED.

3384 (1917). Elektro-Osmose A.-G. Purifying and enriching immunising serum. (104,688.) Mar. 16.
10,050 (1919). Marks (New Jersey Testing Laboratories). Production of reactive acid liquor alcohols, esters, etc. from olefine hydrocarbons. (160,185.) Mar. 31.

I.—GENERAL; PLANT; MACHINERY.

Patents.

Heat of liquids; Apparatus for utilising the —— for heating other liquids. E. Wirth-Frey. E.P. 125,368, 21.3.19. Conv., 12.4.18.

Vapour of a liquid contained in one vessel is passed into a liquid contained in another vessel by means of a suction and compression pump between the two vessels, or by means of a vacuum pump drawing from the top of the second vessel. Several vessels may be interconnected, so that heat may be transferred from any one to any other, and air may be bubbled through both the liquids to assist the process.—B. M. V.

Drying material containing liquid; Process and apparatus for ——. G. Schjelderup. E.P. 139,478, 23.2.20. Conv., 24.2.19.

A dryer, specially suitable for ore flotation concentrates, is formed of a series of superposed metallic hearths somewhat similar to a mechanical roaster, the material being rabbled from circumference to centre and *vice versâ* on alternate hearths. The vapour arising from the material being dried is drawn off, compressed, and returned to the interiors of the hearths, where it condenses and gives up its heat to the material; the vapours pass upwards through all the hearths in succession, countercurrent to the material being dried, and to afford the initial heat to prevent condensation in the drying chambers the material is preheated, part of which heat may be derived from the heat remaining in the condensed liquid. The admission of wet and withdrawal of dry material may be effected through airtight doors so that there is no loss of dust or vapour.—B. M. V.

Drying-stoves and the like; Gas-fired ——. W. Muirhead. E.P. 159,393, 13.1.20.

A drying chamber is connected with a pair of longitudinal regenerators below by a series of openings along each side at the bottom. Gas is burned in one of the regenerators, and the hot gas passes transversely across the drying chamber to the other regenerator, which is thus heated. The functions of the two regenerators may be reversed by dampers controlling the air and gas passages.—W. F. F.

Drying plant. P. Barducci. U.S.P. 1,368,537, 15.2.21. Appl., 19.1.20.

Material is placed in a drying room through which a carriage travels horizontally. The carriage comprises a casing with a horizontal top, in which are openings arranged in lines transverse to the path of the casing, and an internal propelling device which causes a circulation of air through the casing and around a horizontal axis in the room.
—W. F. F.

Air heater for drying apparatus. O. Pfeiffer. G.P. 329,828, 8.2.19.

The air to be heated and the heating gases flow through a series of chambers constructed of parallel plates, the opposite sides of alternate chambers being open, so that the paths of the air and of the heating gases cross one another at right angles.
—L. A. C.

Drying apparatus; Rotary —— [for drying yeast or milk or other material liable to froth]. L. Eberts. G.P. 330,129, 1.5.18.

The feed tube, provided with a slit through which the material is supplied to the drying surface, is connected with an overflow tube which returns excess material to the reservoir.—L. A. C.

Separation of a solvent from a material with simultaneous drying; Process and apparatus for ——. Trocknungs-Anlagen G.m.b.H. G.P. 330,449, 19.9.19.

A blast of cold air is injected into the hot solvent vapour, which is thereby condensed and falls into a receiver, while the warm air is employed for drying the material.—L. A. C.

Furnace for the continuous drying or ignition of substances without exposure to a direct fire. Farbenfabr. vorm. F. Bayer und Co. G.P. 331,784, 18.11.17.

The substances to be dried are enclosed in drums which, by means of rings running on rails, are made to move down the inclined hearth of a furnace. The revolution of the drums serves to keep the contents thoroughly mixed.—A. R. P.

Dryers; Stirring apparatus for revolving tube ——. Maschinenfabr. Buckau A.-G. zu Magdeburg. G.P. 332,050, 27.1.18.

A freely-moving cylindrical body of smaller cross-section than the drying tube is placed inside it, so that during the revolution of the tube it rolls round the walls and not only shakes the contents up, but stirs them about. Means are provided to prevent the roller from falling out of the tube.—A. R. P.

Separating solid substances from gases and vapours, more especially blast furnace gases; Apparatus for ——. Deutsche Maschinenfabrik A.-G. E.P. 148,802, 10.7.20. Conv., 2.12.18.

The filtering surfaces are built up of a number of units, which can be withdrawn individually or in groups, a number of rings of such units being assembled one above the other, so as to form a central outlet conduit for clean gas. The sectional plan view may be similar to a cog wheel with very deep teeth.—B. M. V.

Electrical treatment of gases; Apparatus for ——. A. Mond. From International Precipitation Co. E.P. 158,982, 13.11.19.

An electrical precipitator for removing suspended particles from gases comprises vertical collecting electrodes consisting of tubes or plates of relatively large cross-section and discharge electrodes consisting of smooth bars, rods, or twisted square rods of metal, of relatively small cross-section, arranged about a common axis within or between the collecting electrodes. The discharge electrodes are supported at their upper or lower ends only. Matter deposited upon the collecting and discharge electrodes is dislodged therefrom by blows delivered by hammers to plates mounted on and between adjacent collecting electrodes and to the supports of the discharge electrodes. Means are provided whereby such blows may be delivered without interrupting the electric current.—J. S. G. T.

Discharge electrode for high-tension current used in the purification of gases or vapours. H. Zschocke. G.P. 331,381, 21.10.19.

Metallic bands in the form of rings or helices are wound upon the two limbs of a U-shaped, perforated hollow body, so that there is a narrow gap between adjacent windings, through which either purified or unpurified gas may be passed. When the gas is not heavily charged with dust particles the unpurified gas is fed to the interior of the electrode. In other cases, as, for example, when the gas is heavily charged with dust particles which might choke up the narrow slots, a small current of purified gas is fed to the electrode, while the crude gas is fed longitudinally between the discharge and precipitating electrodes.—J. S. G. T.

A

Electrode for use in the [electrical] deposition of dust. H. Thein. G.P. 331,590, 20.8.19.

THE electrode is constituted of a flexible hollow body such as metallic tubing.—J. S. G. T.

Electrical purification of gases; Process for the removal of dust deposited in the ——. H. Zschocke. G.P. 332,110, 5.11.19. Addn. to 329,062 (J., 1921, 205 A).

THE deposition tubes and the axes thereof are rotated. The tubes may also be moved simultaneously in an axial direction. The particular motion imparted to the tubes is determined according to the compactness of the dust deposited. —J. S. G. T.

Gas filter. W. M. Bovard, Assr. to N. D. Baker. U.S.P. 1,368,540, 15.2.21. Appl., 14.1.19. Renewed 24.12.20.

A GAS filter is composed of a porous mat of animal and vegetable fibres, mixed with porous mineral matter.—W. F. F.

Filter chamber containing metallic filling for purifying gases. E. Fernholz. G.P. 330,356, 7.3.20.

THE filling bodies are connected together, *e.g.*, by soldering, to avoid the necessity for supporting the bodies by perforated plates to prevent uneven packing and formation of gas pockets.—L. A. C.

Gas filters containing granular or fibrous material; Method of attaining uniform filtrations with ——. Tellus A.-G. für Bergbau und Hüttenindustrie. G.P. 330,450, 7.11.19.

THE filter is packed so that the permeability of the filtering material decreases in the direction of the current of gas.—L. A. C.

Precipitation of solid or liquid impurities from streams of gas or vapour; Apparatus for ——. G. Klingenberg. G.P. 332,164, 5.9.19.

A NUMBER of plates are arranged transversely to the gas stream, and the spaces between the plates are divided by partitions at right angles to the plates. Both plates and partitions are provided with openings, which are so disposed that the gas in passing between successive plates has to flow through the openings in the partitions. Deposition of solid and liquid particles is effected owing to the change of direction of the stream, and by the retardation occurring when the cross-sectional area increases. Solid particles may be collected and removed by a stream of fluid flowing at right angles to the main gas stream.—J. S. G. T.

Gas scrubber. A.-G. der Dillinger Hüttenwerke, and R. Kunz. G.P. 326,964, 22.11.18.

THE scrubber is filled with alternate layers of distributing cones and collecting funnels, and the upper surfaces of the cones and funnels are provided with radial grooves to equalise the distribution of the water and thus increase the efficiency of the scrubbing action.—L. A. C.

Separating aqueous and other vapours from liquids and solids, and preparing dilute sulphuric acid; Process of ——. O. Maass. E.P. 159,054, 3.12.19.

MATERIAL to be treated is contained in a vessel which is evacuated as completely as possible by oscillation of an absorbing or desiccating agent, *e.g.*, concentrated sulphuric acid, in a suitable pumping device connected with the vessel. During such oscillation the desiccating agent passes over a distributing surface, whereby large superficial contact is maintained between it and the vapour derived from the material under treatment. If necessary, heat may be applied to the material. The process may be applied to the concentration of weak solutions of hydrogen peroxide, the preparation of milk powder, etc.—J. S. G. T.

Crushing mills of the roller and ring type. C. M. Conder and G. T. Vivian. E.P. 159,244, 10.10.19.

A PAIR of rollers and a ring inside which they run are all supported on parallel horizontal shafts, one of the roller shafts and the ring shaft having sliding bearings, so that each roller may be pressed equally on the ring by means of springs between the two bearing boxes. The pressure can be adjusted by a nut turning upon a screwed pin inside one of the bearing boxes, the pressure being taken off the threads after adjustment by means of shims. The top half of the casing of the machine is in two parts, each part being hinged to the lower part of the machine.—B. M. V.

Pulverising machine. O. A. Kreutzberg. U.S.P. 1,368,636, 15.2.21. Appl., 8.11.19. Renewed 8.7.20.

Two cones of wide angle are mounted on separate parallel shafts so that their conical surfaces are in line contact. One cone is provided with a segment of its conical surface slightly raised above the remainder, and the other cone is movable axially on its shaft against a spring to allow the passage of the raised portion past the line of contact. —W. F. F.

Mill; Ball-grinding ——. P. T. Lindhard, Assr. to F. L. Smidth & Co. U.S.P. 1,368,739, 15.2.21. Appl., 15.5.19.

MATERIAL is fed through a horizontal axial passage into a horizontal grinding drum, and passes through a perforated transverse plate at the other end on to a cylindrical screen. The finer material passes through the screen to the discharge, and the coarser material is collected by scoops and conveyed to an axial conduit passing through the discharge conduit, back to the grinding drum.—W. F. F.

Pulverising or comminuting apparatus. C. E. Tetley. U.S.P. 1,369,061, 22.2.21. Appl., 10.7.19.

A GRINDING apparatus comprises a series of short drums placed concentrically end to end and communicating with one another. The inner surface of each drum is curved to a barrel shape, and the successive drums are of decreasing size from the inlet to the outlet end. The drums are rotated on their axes, and each is provided with a loose ball. —W. F. F.

Ball or tube mills; Discharge spout for ——. N. L. Hall. U.S.P. 1,369,653, 22.2.21. Appl., 2.8.20.

THE horizontal hollow discharge trunnion of a rotating ball or tube mill is provided with a number of short internal vanes with helical surfaces. The heavier material is intercepted and returned to the mill by the vanes, and the lighter material is discharged.—W. F. F.

Furnaces; Recuperative ——. W. S. Rockwell, Assr. to W. S. Rockwell Co. U.S.P. 1,358,330, 9.11.20. Appl., 4.11.19.

A HEATING chamber is provided with burners arranged along the side walls and delivering gas into mixing chambers in the walls. Each air supply conduit passes upwards through the side wall and enters the mixing chamber at the bottom, while the delivery port into the furnace is constricted sufficiently to draw in the air through the supply passage. The combustion products pass from the heating chamber through openings at the bottom into a chamber below, which extends the full length and width of the floor, and the gases then pass in a tortuous path through a pair of regenerators below, which preheat the air supply.—W. F. F.

Furnace; Refractory ——. W. J. Hill. U.S.P. 1,363,787, 28.12.20. Appl., 5.3.20.

The lower part of the heating chamber is filled with a refractory radiating element consisting of layers of bricks arranged alternately in longitudinal and transverse rows with intervening spaces. A central longitudinal outlet flue runs along the bottom of the structure and is provided with side openings leading to side flues. A flame is projected horizontally into the upper part of the furnace from a burner at one end, and is deflected downwards through the radiating element by a horizontal plate surmounted by a vertical longitudinal plate, which lies along the top of the structure. The horizontal plate is arranged centrally but is of less width than the furnace.
—W. F. F.

Reverberatory furnace; Process for heating solid material in a ——. Magnesit-Ind. A.-G. G.P. 329,825, 20.12.18.

The solid hearth is replaced by a cooling shaft into which the material falls, the portion of the material immediately under the influence of the flame being supported by the material cooling in the shaft.
—L. A. C.

Air-separator. T. J. Sturtevant, Assr. to Sturtevant Mill Co. U.S.P. (A) 1,367,635, (B) 1,367,636, and (C) 1,367,637, 8.2.21. Appl., (A) 24.1.20, (B) (C) 16.2.20.

(A) Material is fed into an air current by another air current which is caused to whirl and so project the material transversely into the separating current. (B) The separating air current moves upwards in a chamber, and the material is fed into the chamber by another current moving upwards. The feeding current is received by a rotating device which whirls it horizontally into the separating current. (C) Air is circulated upwards through a separating chamber and then back through a by-pass to the bottom of the chamber, while material to be graded is introduced into the by-pass. The mixture is whirled by a fan into an outer collecting chamber and the material is removed before the air passes back to the by-pass.—W. F. F.

Mixing granular substances; Apparatus for ——. O. Krause. U.S.P. 1,369,248, 22.2.21. Appl., 23.11.20.

The substances to be mixed are supplied through separate discharge shoots, along which the substances slide and from which they fall freely through the air in a parabolic path. The shoots are so inclined that the substances all meet at a common point in their fall and follow each other throughout the remainder of the fall as a uniform mass to a place of collection.—D. W.

Still. A. C. Jewell. U.S.P. 1,369,438, 22.2.21. Appl., 23.10.17.

The vapour generated in a still passes upwards through a vertical column which opens at the top into an annular chamber surrounding the column. The wall of the column, which forms the inner wall of the annular chamber, is made double, and a current of air is passed upwards through the jacket thus formed which opens at the top into the annular chamber. The annular chamber is surrounded by a water jacket and acts as a condenser.—W. F. F.

Salts or other granular or slimy material; Apparatus for washing ——. E. Waskowsky. G.P. 328,752, 22.8.17, and 330,255, 14.8.18.

The apparatus consists of two washers worked on the counter-current principle and provided with a conveyor the blades of which may, if necessary, be perforated and provided with outer rims. The conveyor may be in the shape of a drum with a solid or perforated casing, and the washing apparatus is then provided with a sieve, from underneath which the washed material is removed.—A. R. P.

Washing granular filter material by means of compressed air and water; Process for ——. K. Morawe. G.P. 328,943, 28.1.19. Addn. to 311,593 (J., 1919, 522 A).

Alternate lateral motion and rearrangement of the filter material is effected by the operation of a siphon, whereby, alternately with the addition of washing water, a corresponding mass of sludge is raised above the filter bed. The lower limb of the siphon passes into the filter bed and a plate arranged at the entrance to the siphon prevents the filter material being carried over.—J. S. G. T.

Filter press and frame, in which the filter cloths are separated by lattice work. K. u. Th. Möller G.m.b.H. G.P. 332,163, 28.4.20.

The lattice employed is designed so that its profile shows a double flange. The filter surface may then be increased, as the number of supports of the filter cloth upon the double flanges may be varied according to the nature of the liquid to be filtered, and the pressure employed can be altered by variation of the depth of profile and of the distance between the lattices. Corrugated cross-pieces may be used to form the lattices, which may be installed at a distance from one another, leaving an unrestricted channel between.—J. S. G. T.

Solutions; Evaporating atomised ——. *Evaporating and effecting chemical reactions in atomised solutions.* G. A. Krause und Co., A.-G. G.P. (A) 329,357 and (B) 329,358, 30.1.17. Addns. to 297,388.

(A) A horizontal or inclined stream of the atomised liquid is injected into a vertical current of warm, dry gas. (B) The atomised liquid is injected in a nearly horizontal disc-shaped stream into a descending current of warm, dry gas, and the dried product is thus carried directly down to the bottom of the drying chamber.—L. A. C.

Evaporation of solutions of salts etc.; Rotating drum for the ——. G. Sauerbrey Maschinenfabrik A.-G. G.P. 330,357, 10.10.18.

The drum is provided with lifting scoops extending the length of the drum and so arranged that the liquid circulating in the drum meets a number of transverse surfaces between the scoops at such an inclination that transport of the deposited salt along the length of the drum is effected. A central conveyor for removing the salt is thus rendered unnecessary.—J. S. G. T.

Evaporator. B. Graemiger. G.P. 331,792, 6.9.19.

An evaporator with vertical heating tubes is provided with a double-walled fall tube, the outer casing of which is closed at the top where the tube for admitting fresh supplies of liquid is connected, and open at least for the greater part of its ring-like cross-section towards the container from which the series of heating tubes is fed. The fresh liquid which flows down the outer casing prevents the evaporated liquid in the inner tube from receiving so much heat that it is evaporated still further with evolution of steam bubbles and consequent hindering of its sinking.—A. R. P.

Liquefaction of gases; Process for the —— *and for producing low temperatures by releasing gases under pressure.* B. Haak. G.P. 329,361, 15.11.14.

The necessary high pressure is attained by the electrolytic generation of the gas under pressure; *e.g.*, liquid oxygen and hydrogen are prepared by

the fractional condensation of the mixture of gases obtained by the electrolysis of water.—L. A. C.

Lining for protecting apparatus and vessels employed in chemical technology against chemical action. F. Schüler. G.P. 329,659, 28.11.19. Addn. to 318,033 (J., 1920, 356 A).

A single layer of stoneware protected by a coating of silicate or by glass sheets is used. Thin strips of glass are laid under the joints of the glass sheets, or folds engaging with one another may be provided in the sheets. The stoneware covered with silicate should be provided with expansion joints and these filled with acid-resisting material.
—J. S. G. T.

Vessels having worm coils within the walls; Manufacture of ——. Maschinenfabr. Esslingen. G.P. 330,018, 12.5.18.

The walls of the vessels are made of ferrosilicon containing 12—18% Si which is cast around an iron worm tube (*cf.* G.P. 306,001; J., 1918, 628 A).
—L. A. C.

Pressing, leaching, distilling, extracting, rinsing, separating, and dissolving materials and effecting chemical reactions; Means for ——. O. Endriss. G.P. 330,225, 26.1.18.

Two bodies of the material are compressed together so that any liquids or gases formed or expressed can flow away without employing a sieve or filter cloth, or a single body of the material is compressed against a solid wall or walls.—L. A. C.

Filling material for reaction chambers. J. Thede. G.P. 330,226, 25.3.20.

Thorough admixture of the gases in a reaction chamber, *e.g.*, in the manufacture of sulphuric acid by the lead chamber process, is attained by providing the filling material with slanting channels of varying depth whereby variations in velocity and vortex motions are imparted to the gases flowing through the chamber.—L. A. C.

Drying solutions; Process for —— by removal of part of the solute by addition of a solid substance. E. Harsányi and K. Medgyes. G.P. 331,142, 8.10.19. Conv., 28.11.17.

A sufficient quantity of the dried solid substance from a previous operation is added to a solution of the same substance to give on standing a homogeneous crumbly mass which may be readily dried by known methods. For example, 100 g. of gelatin, dried at 105° C. and crushed to 1 mm. size, is mixed while still warm with 55 g. of a 5% gelatin solution at 70° C.; after standing for 15—25 mins. the solution sets to a mass which readily crumbles to a powder, containing 16% of moisture. 30 g. of this product is removed and the remainder dried at 105° C. and used again in the process.—A. R. P.

Leaching vegetable, animal, or mineral substances; Process and apparatus for ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). E.P. 145,045, 14.6.19. Conv., 9.1.15.

See G.P. 294,667 of 1915; J., 1917, 377.

Pulverising or fine grinding; Process and apparatus for ——. F. Seymour. E.P. 159,925, 7.11.19.

See U.S.P. 1,363,361 of 1920; J., 1921, 135 A.

Refrigeration; Method of ——. Refrigerating apparatus. B. Thoens. U.S.P. 1,369,365-6, 22.2.21. Appl., 28.5 and 22.12.19.

See E.P. 152,898 of 1919; J., 1920, 809 A.

Recuperators for use in connexion with furnaces. H. Hecker, and Bender und Främbs Ges. E.P. 133,046, 24.9.19. Conv., 10.9.18. Addn. to 133,045.

Furnaces; [Silencing and heat-guarding casing for] oil-fired ——. Manlove, Alliott and Co., and F. L. Mason. E.P. 159,391, 8.1.20.

Carboys; Packing-cases for ——. S. Percival. From Illinois Glass Co. E.P. 159,394, 16.1.20.

Crushers. A. Mond. From Traylor Engineering and Manufacturing Co. E.P. 159,950, 1.12.19.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Karbozit. H. R. Trenkler. Feuerungstechn., 1921, 9, 93—95.

Karbozit is produced from lignite, wood, or peat by heating the raw material to a temperature not exceeding 450° C. By this means all the original water, together with a large amount of carbon dioxide, is evolved, thus concentrating the combustible matter in less mass. The material is dried to a moisture content of 10—15% by means of a mixture of air and hot waste gases at 75° C. in drying bunkers arranged over the ovens. Dry coal is sifted, the fines being gasified in producers and the large coal passed into an annular chamber, the lower part of which forms a cooler. Heat is applied by passing hot gases through the charge, a temperature of 250°—300° C. being maintained. Any tar produced is drained off below and allowed to mix with the "Karbozit." From a coal of composition, C 27·37%, H 2·00%, O and N 10·78%, S 0·54%, ash 3·23%, moisture 56·08%, and calorific value 2110 cals. per g. there was produced a fuel containing C 69·31%, H 4·12%, O and N 13·90%, S 0·91%, ash 5·32%, moisture 6·44%, and calorific value 6290 cals. per g. The great drawback to the process is that fines cannot be utilised.—A. G.

Petroleum; Formation of —— from fish oils. Origin of Japanese petroleum. K. Kobayashi. Kôgyô-Kwagaku Zasshi (J. Chem. Ind. Japan), 1921, 24, 1—26.

By distilling a mixture of herring oil (4000 c.c., sp. gr. 0·9214, saponif. value 187·7) and finely powdered Japanese acid clay (4000 g.) covered with the same clay (4000 g.) in an iron retort at ordinary pressure, the author obtained a crude oil (2000 c.c.) and water (1800 c.c.). Among the products were acrolein, carbon dioxide, soluble fatty acids, such as acetic acid, other fatty acids, naphthenic acids, and hydrocarbons. The oil distillate (sp. gr. 0·8160 at 15°/4° C., saponif. value 15·1, percentage absorbed by concentrated sulphuric acid 14·5) had a greenish fluorescence and a petroleum-like odour and closely resembled natural crude petroleum. The hydrocarbons in the oil were mainly of the naphthene series, together with a considerable quantity of olefines. The formation of the hydrocarbons is ascribed to the action of the Japanese acid clay $Al_2O_3,6SiO_2,xH_2O$ (J., 1920, 655 A). The oil is hydrolysed to fatty acids and glycerol by the action of water in the clay, and the fatty acids are decomposed into hydrocarbons partly with formation of acetic and naphthenic acids and mainly by the elimination of carbon dioxide. The hydrocarbons thus formed are "cracked" to lighter ones by the heated surface of the upper layer of clay. There are very close geological relations between the oil fields and the outcrops of Japanese acid clay, and Japanese petroleum is accompanied by salt water. It is suggested that Japanese petroleum and oil gas

are formed from marine animals. Fish oils, produced from fishes by putrefaction etc., are decomposed to petroleum and oil gas, according to a process similar to that described above. The naphthene hydrocarbons are probably derived from unsaturated fatty acids, and hydrocarbons of the C_nH_{2n-2}, C_nH_{2n-4}, etc. series from more highly unsaturated acids.—K. K.

Patents.

Coal; Apparatus for washing ——. F. Courtoy. E.P. 154,167, 24.2.20. Conv., 14.11.19.

The coal and water are fed in at the upper part of a hopper with an inclined bottom, provided with an adjustable opening for the issue of coal near the bottom and at the top with an outlet for the ash-containing slimes, carried along by the current of water; in front of the upper outlet is a vertical wall against which the scum of the slimes with smaller ash content collects. The adjustment of the coal outlet is effected automatically by means of a float guided so that when the quantity of coal fed in by the water increases the float rises, thus giving a wider passage towards the outlet and *vice versâ*. The upper and lower currents can be adjusted by means of flap-valves placed between the float and the outlet.—A. G.

Coal; Treatment of materials containing ——. E. Edser, H. L. Sulman, and F. B. Jones. E.P. 159,285, 20.11.19.

The powdered material, suspended in liquid, is subjected to agitation and/or aeration to disseminate minute air bubbles throughout the liquid in such a way that the coal particles are caught in the air-water surface of the bubbles and floated in the form of a froth and are thus separated from the gangue. The liquid consists of water containing in solution a modifying or deflocculating agent, *e.g.*, sodium silicate, silicic acid sol, sodium carbonate, caustic soda, or other suitable alkali or mixtures of these. When it is desired to separate the coal entirely, cresol or other frothing agent is added to the solution. An insoluble agent, such as paraffin oil, may be added to stabilise the froth, whereby carbonaceous shale may be floated along with the coal. Common salt may also be used in the liquid, and for the promotion of aeration, a vegetable infusion may be added, such as an infusion of saponin, cinchona, or quassia.—A. G.

Briquetting apparatus. C. W. G. Clewlow. E.P. 158,686, 10.11.19.

In an apparatus for converting pulverised coke breeze or anthracite dust into briquettes for fuel, molten pitch is added to the solid material in a hopper provided with revolving paddles. The delivery nozzle for the pitch is connected with the stirring apparatus, so that the jet follows the paddles. The mixture is transferred to another vessel, where it is subjected to the action of steam and hot gas, which may be supplied through co-axial nozzles.—W. F. F.

Pulverised fuel; Manufacture of mixtures of —— *with tar or other liquid fuel.* A. McD. Duckham. E.P. 159,089, 24.1.20.

To obviate the necessity of drying the coal before grinding, and to overcome the danger caused by fine coal dust in suspension in grinding plants, the coal is ground in the presence of the liquid fuel. —A. G.

Fuel; Process for drying wet ——. C. Christians. G.P. 330,924, 17.5.13.

The hot gaseous products of combustion of fuel are passed over the wet fuel in such a manner that the moisture is evaporated from that part of the wet fuel that is nearest the inlet tube for the gases and condenses in that part which is more remote, from which it is removed in the liquid state by suitable outlet pipes.—A. R. P.

Fuel; Process of oxidising ——. T. J. Stephens, Assr. to Stephens Engineering Co. U.S.P. 1,369,200, 22.2.21. Appl., 26.12.18.

Ground fuel is mixed with an oxidising medium, and the mixture is passed downwards into one side of a zone maintained at a temperature which promotes ignition, whereby the finer particles in suspension are burnt, whilst the larger particles are deposited to form a non-coherent bed. The particles which compose the portions of this bed opposite to the side at which downward projection occurs are agitated by a projected stream of additional oxidising medium.—A. G.

Coke or carbon; Apparatus for separation of —— *from slag or the like.* Soc. "Le Coke Industriel." E.P. 149,654, 10.6.20. Conv., 13.8.19. Addn. to 120,932 (J., 1919, 672 A).

The top plates of the separating compartments are in two parts and have a double joint, which allows them to be inclined and, consequently, the widths of the upper openings of the compartments to be varied at will, with a view to regulating the speed of the ascending currents of water.—A. G.

Coke ovens. La Soc. de Fours à Coke et d'Entreprises Industrielles. E.P. 130,974, 22.7.19. Conv., 9.8.18.

A coke oven has reversible regenerators running longitudinally below the ovens, and vertical flues which are connected with regenerator compartments on both sides of the heating wall. Each regenerator is divided into four compartments corresponding to four sets of flues. The oven may be heated by rich gas, in which case the gas is supplied cold, the air for combustion is heated by passing through two regenerator compartments, and the combustion products pass through the other two compartments. When poor gas is used the gas is heated in two compartments of a set below one oven and the air in the corresponding compartments of the set below the adjacent oven.—W. F. F.

Coking retort-oven. H. Koppers, Assr. to The Koppers Development Corp. U.S.P. 1,369,673, 22.2.21. Appl., 10.9.20.

The distillate is withdrawn from the coking charge in one direction until the distillation of the mass has been almost completed, and is then withdrawn in the opposite direction during the continuance of the coking operation. By such reversal in flow of the distillate through the charge the hotter regions of the charge are cooled and over-coking thereof is retarded. The cooler portions of the charge are also completely coked.—A. G.

Gas producers. C. B. Tully. E.P. 159,409, 19.2.20.

In gas plants where steam is supplied intermittently to the producer, and where the gas is led off past a gas valve of the lift type immersed in liquid within a box, a lever for moving the gas valve is interconnected with the steam valve used for admitting steam to the producer, and hand-operated means are provided so that the gas and steam valves can be opened or closed together.—A. G.

Fuel; Manufacture of —— *from crude petroleum oil or residues thereof by distillation.* H. Wade. From Standard Oil Co. E.P. 158,918, 21.7.19.

The oil is distilled continuously by passage through a series of stills which are fired externally and heated internally by live superheated steam to pro-

gressively higher temperatures. The temperatures are adjusted to yield approximately the same volume of distillate from each still and to yield from the last still a residual pitch of m.p. at least 295° F. (146° C.) by the ball and ring test, which is suitable for use as fuel, either alone or mixed with powdered coal or the like.—L. A. C.

Benzol mixtures; Preparation of —— which remain liquid at low temperatures. Tetralin G.m.b.H. G.P. 329,833, 29.3.16.

THE addition to benzol, with a low toluene content, of hydronaphthalenes consisting chiefly or wholly of "decahydronaphthalene," increases its energy without materially affecting the ignition point. The freezing point of a mixture of 90% of benzol and 10% of "decahydronaphthalene" is −3° C.; a 70:30% mixture freezes at −20° C.—W. J. W.

Lubricants. J. J. Hood, H. Spence, and P. Spence and Sons, Ltd. E.P. 158,922, 16.8.19.

A LUBRICANT consists of a suspension of aluminium powder, with or without the addition of other finely divided solids, such as mica or graphite, in a suitable carrier, such as oil, petroleum jelly, or solidified oil.—L. A. C.

Mine waste [from collieries etc.]; Method of and apparatus for utilising —— by means of the heat of dump-heaps. W. Ostwald, Assr. to The Chemical Foundation, Inc. U.S.P. 1,369,350, 22.2.21. Appl., 21.7.16.

SEE E.P. 107,446 of 1916; J., 1917, 956.

Peat; Method and means for removing water from ——. A. ten Bosch, Assr. to N. V. Nederlandsche Veenverwerking Maatschappij. U.S.P. 1,369,611, 22.2.21. Appl., 3.10.18.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Wood; Carbonisation of —— by internal combustion engine exhaust gases. L. Tissier. Chim. et Ind., 1921, 5, 136—142.

THE average loss of heat in the exhaust of internal combustion engines is 40%, the temperature of the gases being 400°—450° C. and their composition 78% N_2, 14% CO_2, and 8% O_2. The author has designed a kiln in which such gases pass directly in contact with the charge of wood, heating it to 250° C. and effecting slow distillation. The presence of 7—8% oxygen in the gas is essential to satisfactory carbonisation. The kiln is an upright brick cylinder of 3—12 cub. m. internal capacity, provided with charging and discharging doors, a grate, and gas inlet and exit. One kiln is sufficient for engines up to 60—80 H.P. Condensers for the distillation products may be added. Carbonisation takes 12—24 hrs. In trials in Algeria with light wood cut 8—10 months a yield of 30—33% of charcoal was obtained and with drier material up to 40%. The charcoal is of good quality. The pyroligneous acid contains 6·2% of acetic acid and 1·5% of methyl alcohol. Owing to its slow and perfectly regular action the process offers marked advantages over other methods of wood distillation in both yields and quality of product. The author advocates central plants for working up the crude pyroligneous acid and the use of a part of the charcoal produced for feeding the gas producers generating gas for the engines. It is claimed that it will be more economical even for gas engines at a distance from a forest to transport wood, carbonise it as described, and use the charcoal than to carbonise by less efficient methods in the forest and to transport charcoal. It is calculated that the exhaust from the gas engines of over 25 H.P. running in France and Algeria alone would suffice to effect the world's total present distillation of wood.—C. I.

Shale; Plant design for hot gas pyrolytic distillation of ——. L. Simpson. Chem. and Met. Eng., 1921, 24, 341—345.

IN a plant designed for the economical distillation of 2000 tons of shale per 24 hrs., the shale is crushed, screened, and passed over a magnetic roller. Uniform physical state of the shale before entering the retorts is secured by conveying the screened material through dryers heated by the products of combustion of the steam boilers after those products have been partially cooled in a gas pre-heater. The retorts are of vertical pattern, the upper portion diverging into two separate chambers into which shale is fed by a constant slow-feeding device. Four "double" retorts walled round with double steel plates, packed between with insulating material, form a "bench." Two discharging rollers at the lower end of a retort chamber cause a constant downward movement of shale, which is heated by the admission of preheated gases, the product of a previous operation. These gases are admitted into the chamber at several points and the supply can be controlled. It is claimed that the gas current increases the distillation effect by acting as a carrier for the oil vapours, and also as a diluent, lowering the vapour pressures of the volatile products. Light and heavier oils are condensed separately, and the cooling water from the heavy oil vapour condenser is fed directly to the steam boilers. Spent shale from the retorts is treated subsequently to recover the maximum yield of ammonia at the lowest cost.
—C. A. K.

Patents.

Tar; Process for removing —— from the products of the distillation of wood, coal, and the like. E. Barbet et Fils et Cie. E.P. 158,915, 4.11.18. Conv., 3.11.17. Addn. to 120,558 (J., 1920, 57 A).

The gases issuing from the retorts are bubbled through tar to remove a portion of the tar from the gases, and then through cresol to extract the remainder of the tar. The apparatus is so constructed that loss of heat is reduced to a minimum, and the gases are at a temperature of 115°—130° C. as they pass through the cresol, whereby only tar is retained, and water and acetic acid leave the apparatus as vapour.—L. A. C.

Distilling bituminous coal, brown coal, and shale by superheated steam; Process and apparatus for ——. M. Gercke. E.P. 159,246, 20.10.19.

The coal or shale is subjected to the direct action of superheated steam whilst being continuously conveyed into and through a distilling chamber. The fuel is first preheated by conveying it through a steam-jacketed section or/and through an oil-bath heated to any desired temperature. The coal is conveyed by endless chains comprising articulated members or links formed with pistons which are maintained fluid-tight during their passage through the distilling chamber by labyrinth packings. The steam is conveyed in an unbroken circuit through the distilling chamber, a gas liquor collector, and the steam superheater. The oil bath for preheating the coal is situated in the lower part of the distilling chamber, the oil being circulated by means of a pump, through a heater heated by the waste gases from the steam boiler and also by the steam superheater.—A. G.

Charcoal; Process for producing dense ——. L. F. Hawley, Assr. to The United States of America. U.S.P. 1,369,428, 22.2.21. Appl., 3.4.19.

Charcoal having a density of at least 0·95 is made by forming blocks of comminuted wood, subjecting them to a pressure of at least 30,000 lb. per sq. in., and then distilling them under a direct mechanical pressure, which varies periodically between 50 and 120 lb. per sq. in.—W. F. F.

Illuminant [; Hydrogenated naphthalene as ——]. K. Wimmer. G.P. 302,488, 23.7.15.

Hydrogenated naphthalene, either alone or mixed with other illuminants, burns, *e.g.*, in a paraffin lamp, with a flame of high luminosity. A suitable catalyst for the hydrogenation of naphthalene is prepared by reducing dry nickel formate or the like made to a paste with or dissolved in oil. For the production of "decahydronaphthalene" the hydrogenation is effected at 180°—200° C. and 30 atm.—L. A. C.

Ductile tungsten. E.P. 155,851. *See* X.

III.—TAR AND TAR PRODUCTS.

Anthracene; Formation of —— from benzene and ethylene. J. E. Zanetti and M. Kandell. J. Ind. Eng. Chem., 1921, **13**, 208—211.

Anthracene is formed when benzene vapour and ethylene are passed through a heated quartz tube. The optimum temperature is 925° C., the yield being 0·675% of the benzene; above this temperature the yield decreases, and none is formed at 1000° C., whilst the amount of carbon produced increases.—W. P. S.

Electrolytic reactions of naphthalene and its derivatives. I. Electrolytic oxidation of naphthalene. K. Ono. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, **42**, 38—66.

Naphthalene is oxidised electrolytically to α-naphthoquinone, together with phthalic acid and a dark-brown resinous substance, in acid solution (mixtures of sulphuric acid and acetone or acetic acid), using a lead peroxide or platinum anode. A mixture of 100 c.c. of water and 20—30 c.c. of sulphuric acid (sp. gr. 1·84) is a suitable electrolyte. With increase of current density the amount of naphthalene oxidised increases, but the yield of α-naphthoquinone does not increase proportionately; a suitable current density is 2 amp. per 100 sq. cm. for a lead peroxide anode and 3 amp. per 100 sq. cm. for a platinum anode. The amount of oxidation increases with rise of temperature, and the yield of naphthoquinone increases proportionally with a platinum anode, whereas with a lead peroxide anode the best results are obtained at room temperature. With increase in the quantity of electricity the yield of naphthoquinone diminishes, and secondary reactions take place with formation of a dark-brown substance. As oxygen-carriers, cerium nitrate, vanadic acid, potassium chlorate and chromate, manganous sulphate, potassium ferrocyanide, and chrome alum are effective in the above order. α-Naphthol and a compound of α-naphthol and naphthoquinone were detected in the reaction products. (*Cf.* J.C.S., Apr.)—K. K.

Acetylene; Condensation of —— with benzene and its derivatives in the presence of aluminium chloride. O. W. Cook and V. J. Chambers. J. Amer. Chem. Soc., 1921, **43**, 334—340.

Benzene and its derivatives condense with acetylene in the presence of aluminium chloride to give αα-diarylethanes and derivatives of anthracene. Only a trace of styrene was found when benzene was condensed with acetylene. Certain derivatives of benzene, owing to preliminary reaction or condensation with aluminium chloride, do not act further with acetylene. (*Cf.* J.C.S., May.)—W. G.

Phenol; Interaction of tin and ——. H. F. Zoller. J. Amer. Chem. Soc., 1921, **43**, 211—212.

When phenol is slowly distilled in the presence of tin it is partly decomposed, benzene and stannic oxide being formed. In one experiment about 30 c.c. of benzene was obtained from 200 g. of phenol. The reaction is practically negligible at the ordinary temperature, but is of importance in the manufacture of phenol and its use in serum laboratories.—W. G.

Patents.

Hydronaphthalenes; Manufacture of ——. Purification of technical naphthalene for the manufacture of hydronaphthalenes. Tetralin G.m.b.H. G.P. (A) 324,861, 25.2.15, (B) 324,862, 1.8.15, and (C) 324,863, 14.5.16.

(A) Technical naphthalene, after purification as described in (B) or (C), is heated to 150°—200° C. under a pressure of 10 atm. with sufficient hydrogen to produce the desired hydrogenated product. "Decahydronaphthalene" is not formed until the whole of the naphthalene has been reduced to tetrahydronaphthalene. Technical naphthalene is purified by agitation above 100° C. with a finely powdered or porous material, such as fuller's earth, kieselguhr, or animal charcoal, and (B) a finely divided or low-melting metal, such as nickel or sodium, or (C) an unstable compound of a metal with a non-acid residue, *e.g.*, a metallic amide or carbide, such as sodamide or calcium carbide, or

with the metal or metallic compound alone, with subsequent distillation under reduced pressure. —L. A. C.

Methyleneanthraquinone and its substitution products; Preparation of ——. K. H. Meyer. G.P. 330,550, 16.9.19.

The compounds claimed, which serve as intermediates in the manufacture of vat dyes, are prepared by condensing anthranol or its substitution products with formaldehyde in alkaline or acid solution, with the exception of concentrated sulphuric acid. A solution of α-hydroxyanthranol in hot 5% sodium hydroxide solution yields with formaldehyde a light-brown precipitate. A mixture of glacial acetic acid and concentrated hydrochloric acid may also be used as the condensing agent.—L. A. C.

Illuminant. G.P. 302,488. *See* IIb.

IV.—COLOURING MATTERS AND DYES.

Indigotin; Constitution of ——. R. Robinson. J. Soc. Dyers and Col., 1921, 37, 77—81.

The case of indigotin is taken as an example of the manner in which partial valency formulæ may be employed to symbolise more accurately than is possible with expressions involving normal valencies only, the properties and relations of chemical individuals. Colour intensification by auxochromes is attributed to the making and breaking of partial valencies. Attention is drawn to the analogy between indigotin and indanthrene, and the probability that the cause of the colour resides in the interaction of the nitrogen atoms and the oxygen of the quinone groups is demonstrated by a consideration of the variations caused in each series by exchanging S and O for one or both of the NH groups. In both indigotin and indanthrene there is a double possibility of partial valency union between quinonoid oxygen and the auxochrome nitrogen, and the author's formulæ express this view of the origin of colour, and also fully symbolise the chemical properties of these compounds. —F. M. R.

Lake. U.S.P. 1,369,252. *See* XIII.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Fabrics; Tensile, bursting, and ripping strain of ——. J. Huebner. J. Soc. Dyers and Col., 1921, 37, 71—75.

The resistance of a fabric to bursting or to ripping often affords valuable information, and in many cases these tests can replace the more tedious tensile test. Determinations of the tensile strain, carried out on hundreds of pieces of four-scoured plain cotton fabrics of different weights, indicate that when ascertaining the effect of chemical agents or processes upon the strength of a fabric, too much value should not be attached to average figures which are obtained from a small number of tests. The bursting strain of the fabric was determined by means of an apparatus of the Mullen type, a circular hole, ½ in. in diam. being punched in the middle of the test piece, as that permits the fabric to give way more readily along the line of least resistance than when a slit is used. Bursting tests with and without the central hole showed a constant ratio, and the former method was adopted owing to the increased life of the rubber diaphragm of the apparatus. The figures obtained show that the bursting strain is comparable with the tensile strain, and that it affords a reliable indication of the strength of the fabric. A ripping test reveals any tendering or change more readily than does a tensile or bursting test. The warp or the weft threads are cut to a depth of 2 ins., and one end of the cut piece is fixed in the upper and the other end in the lower jaw of a Schopper paper-testing apparatus. The jaws are moved apart at a speed of 3 ins. per minute for a distance approximating to 2 ins., and the strain is applied at right angles to the threads to be broken. The figures show that the ripping strains of the lighter fabrics, when compared with those of the heavier fabrics, are proportionally much higher. Tests with plain fabrics, various matt weaves, and sateens, woven from the same quality and quantity of yarn, show that with the exception of the sateens the increased ripping and bursting strains as compared with those of the plain fabric are accompanied by decreased tensile strength. Bleaching increases the tensile strength slightly, but reduces the ripping strain, particularly in the warp way. Tannic acid increases the tensile strength considerably, but the ripping strain remains unchanged, except for a slight reduction in the warp way. The ripping strain is reduced by aluminium and iron mordants, but dyeing with direct and sulphide colours is without effect. The tensile strain is increased by a chromium mordant, but the bursting and ripping strains are reduced. On the whole the strength of linen fabrics is less regular than that of cotton fabrics of equal weights, and whilst the resistance to tensile and bursting strains is similar in each case, the ripping strain of a linen fabric is very much higher than that of a cotton fabric. —F. M. R.

Cellulose; Solubility of —— *in the salts of the alkali and alkaline-earth metals.* R. O. Herzog and F. Beck. Z. physiol. Chem., 1920, 111, 287—292.

The solubility of cellulose in concentrated solutions of alkali and alkaline-earth salts (*cf.* Von Weimarn, J., 1912, 768) is a function of the hydration of the ions of the respective salt. The ions may be arranged in the following order: NH_4<K<Na<Li: Ba<Sr<Ca; $\frac{1}{2}SO_4$<Cl<Br<I<CNS. In experiments with raw and purified cotton, cotton wool, wood pulp, and hydrocellulose, no swelling or solution occurred in solutions of chlorides, bromides, nitrates, sulphates, thiocyanates, acetates, and lactates of sodium, potassium, ammonium, and magnesium, barium and strontium bromides and barium thiocyanate. Calcium nitrate attacked the cellulose. Swelling without disappearance of structure occurred in solutions of potassium iodide at 120°—140° C., and of alkaline-earth iodides at 120°—150° C. Solution of the cellulose took place in solutions of sodium iodide, lithium chloride, bromide, iodide, and nitrate, calcium iodide, bromide, and thiocyanate, strontium thiocyanate, and potassium mercuric iodide. "Commercial pure" calcium chloride will dissolve cellulose if the dilute solution be first neutralised with $N/100$ hydrochloric acid and then concentrated.—S. S. Z.

Spun material resembling wool or cotton; Producing a —— *from viscose solutions.* Glanzfäden A.-G. E.P. (a) 135,205, (b) 152,349, and (c) 152,350, 13.11.19. Conv., (a) 22.2.18, (b) 27.3.18, and (c) 6.4.18.

(a) A material resembling wool or cotton, and not

possessing the high gloss of artificial silk, is prepared by saturating cellulose with an 18% solution of sodium hydroxide, and pressing out excess liquor until the mixture contains about 2 pts. of solution to 1 pt. of cellulose. After treatment with the alkali for not more than 12 hrs., the product is treated with carbon bisulphide, dissolved in weak sodium hydroxide solution, and "spun" in a mineral acid bath before any ripening can set in. (B) If the cellulose has been well opened up by thorough boiling during its preparation, the time of treatment with alkali can be reduced to 10 mins. for a flocky, or 2 hrs. for a matted material. (C) The mixture of cellulose and sodium hydroxide solution is pressed out until it contains not more than 2 pts. of solution to 1 pt. of cellulose, and the temperature of the mixture is not allowed to rise above 20° C. before treatment with carbon bisulphide.—L. A. C.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Mercerisation; Use of caustic potash in ——. E. Ristenpart. Textilber., 1921, 2, 130—131.

COTTON was immersed without tension for 5 mins. in a caustic alkali solution, mangled, washed three times in water, immersed in water over-night, soured with acetic acid, and dried at the ordinary temperature. Comparative tests with solutions of sodium and potassium hydroxides showed that the sodium and potassium alkali-cellulose compounds have similar properties. In very concentrated solutions, caustic soda (owing to its greater viscosity) has less mercerising effect than caustic potash, but under the usual conditions 1 g.-mol. of caustic soda is equal to 1¼ g.-mols. of caustic potash. —A. J. H.

Crêpe-effects; Production of —— *on cotton by mercerisation*. A. Liebmann. Sealed Note, No. 1478, deposited 24.5.04. Bull. Soc. Ind. Mulhouse, 1920, 86, 484. Report by T. Baumann, *ibid.*, 485.

FABRIC which has previously been boiled-out, bleached or mercerised under tension, and dried, is "wetted-out," calendered to remove excess of moisture, dried unevenly according to a desired design by means of hot rollers or plates, mercerised with caustic soda, rapidly rinsed, soured, and washed. The caustic soda affects only the wet parts of the fabric, so that brilliant crêpe-effects are obtained. Baumann reports that satisfactory results are obtained with a fabric previously boiled in a weak solution of sodium carbonate and well bleached. Fabrics boiled with caustic soda give unsatisfactory results.—A. J. H.

Silk; Method for weighting and dyeing ——. A. Tiska. Textilber., 1921, 2, 128—129.

SILK is prepared by steeping it in water at 40° C. for 1 hr., boiling in a 30—35% soap solution, washing, and souring with hydrochloric acid. The silk is weighted 80—100% by immersing it four times alternately in stannic chloride solution of 80° B. (sp. gr. 2·43) and disodium phosphate solution of 7° B. (sp. gr. 1·052) and washing after each immersion. The weighted silk is treated with a warm soap solution for 1 hr., and without washing is dyed black in a bath containing 100% (on weight of silk) of soap and 100% of "logwood crystals." The temperature of the bath is raised from 62° to 75° C. during ¾ hr., 5% of aniline is added, the temperature is increased to 92° C. during ¾ hr., and so maintained for 1 hr. The dyed silk is well washed, treated for ¾ hr. in a warm boiled-off soap bath to which acetic acid and 0·3% of Water Blue have been added, and finally brightened with oil and citric acid.—A. J. H.

Cellulose; Behaviour of highly-oxidised —— *towards direct cotton colours*. E. Knecht. J. Soc. Dyers and Col., 1921, 37, 76—77.

THE behaviour of the oxycellulose previously described (J., 1920, 718 A) towards a number of direct cotton colours has been examined quantitatively. A known weight of the oxycellulose powder was heated for 1 hr., under a reflux condenser, with an excess of the dye solution in presence of sodium hydroxide, the solution then filtered, and the dye remaining in the filtrate titrated in the usual manner. The dye was destroyed by the oxycellulose in an amount which, in some cases, largely exceeded the maximum quantity employed for a full shade in dyeing, but the oxycellulose remained undyed, although its copper number was reduced from 11 to 0·9. Prolonged boiling with the azo dye removed the oxycellulose completely and the remaining cellulose was dyed. The dyeing properties of the oxycellulose can be restored by treatment with sodium hydroxide alone, but the concentration necessary is greater than that used in the dyeing experiments. Direct cotton colours of the Primuline type, which are not affected by reducing agents, dye the highly oxidised cellulose immediately. Such a highly oxidised cellulose is never met with in practice, but the results obtained indicate that the presence of even small amounts of oxycellulose in cotton goods may result in an appreciable loss of dyestuff during dyeing. —F. M. R.

Ice colours; Developers for ——. O. and E. Schlein. Sealed Notes Nos. 1681 and 1743, deposited 5.12.06 and 21.5.07. Bull. Soc. Ind. Mulhouse, 1920, 86, 486—489. Report by P. Binder, *ibid.*, 489—493.

IN the formation of Para Red, solutions of diazotised *p*-nitraniline containing an excess of mineral acid give pale yellowish shades. To obtain rich and bluer shades the free acid must be neutralised with an excess of sodium acetate. A satisfactory and cheaper process consists of replacing part of the sodium acetate by its equivalent of sodium carbonate, in quantity just insufficient completely to neutralise the mineral acid. For the preparation of printing pastes containing diazotised *p*-nitraniline it is preferable to replace all the sodium acetate by its equivalent of caustic soda. Binder reports favourably on the process, although slightly inferior shades are obtained than when sodium acetate is used alone. When disodium phosphate, calcium carbonate, or magnesium carbonate is used in place of sodium carbonate, still less satisfactory results are obtained. In a process communicated by C. Sunder, the diazo solution contains:—2760 g. of *p*-nitraniline, 1500 g. of sodium nitrite, 10,600 g. of hydrochloric acid of 18° B. (sp. gr. 1·143) and 36 l. of calcium acetate solution of 15° B. (sp. gr. 1·116) per 120 l.—A. J. H.

Paramine Brown; Production of discharges on ——. H. Schmid. Sealed Notes Nos. 1504 and 1589, deposited 9.11.04 and 27.12.05. Bull. Soc. Ind. Mulhouse, 1920, **86**, 477—479. Report by C. Sunder, *ibid.*, 481—482.

Good white discharges on a Paramine Brown ground are obtained if the fabric is padded with a solution containing per l., 30—40 g. of *p*-phenylenediamine dihydrochloride, sodium acetate (sufficient to neutralise 50—75% of the hydrochloric acid present), 25—30 g. of sodium chlorate, and 1—10 mg. of vanadium chloride (added just before use), dried, printed with a discharge paste containing hydrosulphite NF, steamed in the Mather-Platt, and washed. For coloured discharges basic dyes are used in the discharge paste and are subsequently fixed with tannic acid. Pure white discharges are also obtained by means of a colourless solution containing per l., 16 g. of *p*-phenylenediamine, 20 g. of ammonium chloride, 20 g. of sodium chlorate, 20 g. of potassium ferrocyanide, and 1·5 g. of Rongalite C, which has been filtered after standing for several hours. The fabric is padded in the solution, dried, printed with a discharge paste containing sulphites or hydrosulphite-formaldehyde and steamed in the Mather-Platt. Coloured discharges may be obtained by the usual methods employed with "prussiate" Aniline Black. Sunder reports that discharges obtained by the first process are not satisfactory, but that this may be due to the impurities present in the *p*-phenylenediamine. Light shades produced by the "prussiate" process appear bronzy and require correction by means of Xanthochromine, Naphthene S, or Fuscamine. No precipitation takes place in the padding mixture when free *p*-phenylenediamine or its acetate is used.—A. J. H.

Discharges on fabrics having a ground formed by the oxidation of an aminophenol; White and coloured ——. H. Schmid. Sealed Note No. 1517, deposited 30.12.04. Bull. Soc. Ind. Mulhouse, 1920, **86**, 479—480. Report by C. Sunder, *ibid.*, 483.

Mono-aminophenols, diaminophenol (amidol), and *o*-anisidine may be oxidised on textile fibres to give brown to dark brown shades, capable of being discharged. The fabric is padded with a solution containing per l., either 40 g. of *p*-aminophenol hydrochloride, 5 g. of acetic acid (50%), 30 g. of potassium ferrocyanide, 25 g. of sodium chlorate, and 4—5 g. of crystalline sodium acetate; or 40 g. of *o*-aminophenol, 40 c.c. of hydrochloric acid of 20° B. (sp. gr. 1·162), 30 g. of potassium ferrocyanide, and 25 g. of sodium chlorate, then dried, printed with a discharge paste containing a mixture of sodium sulphite and sodium acetate, steamed in the Mather-Platt, washed, and soaped. Coloured discharges may be obtained in the usual way with basic and pigment colours. Sunder reports that shades produced from *o*-aminophenol lack depth. The brown shade produced from *p*-aminophenol is somewhat green, and is therefore suitable for correcting the red tone of Paramine Brown. *m*-Aminophenol yields a shade without value.
—A. J. H.

Diastase preparations; New —— and their importance in the textile industry. G. Tagliani. Z. angew. Chem., 1921, **34**, 69—73.

Two preparations, "Fermasol DS" and "Fermasol DB" have been placed on the market recently by the Swiss Ferment Co.; they are rich in animal amylase, liquefy starch rapidly, do not attack or weaken cotton fibres, and possess other advantages over the usual diastatic preparations used in the textile industry. Comparative experiments with these and other diastatic preparations are described.
—W. P. S.

Patent.

Albumins [protalbinic and lysalbinic acids]; Use of decomposition products of —— [in dyeing]. K. Bennert. G.P. 330,133, 25.12.15.

The addition of these acids or their salts to dye-baths, *e.g.*, of vat dyes, produces more level and deeper and brighter shades.—L. A. C.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphuric acid; Supply of nitrogen oxides in the manufacture of —— by the chamber process. S. Pagliani. Giorn. Chim. Ind., 1919, **1**, 57—61.

The author discusses this question, mainly in connexion with the work of Fairlie (J., 1917, 196; 1918, 652 A), Goldmann (J., 1919, 251 A), and Chrisp (Chem. Trade J., 1919, **64**, 91).—T. H. P.

Sulphur dioxide and sulphur trioxide; Determination of —— in burner gases and oleum. A. Sander. Chem.-Zeit., 1921, **45**, 261—263.

A method of estimating sulphur dioxide is based on its conversion by means of sodium hydroxide into bisulphite, and the reaction of the latter with mercuric chloride to form a double salt, with liberation of hydrogen chloride; neutralisation then demands an amount of sodium hydroxide equivalent to that used for the conversion of the sulphur dioxide. 10 c.c. of $N/10$ sodium hydroxide is introduced, together with some methyl orange as indicator, into an absorption flask, provided with a bottom run-off tap. By means of an aspirator, the burner gases are slowly drawn in until neutralisation takes place, and from the known volume of the gases the total sulphur dioxide and trioxide is calculated. The solution is then drawn off, treated with a saturated solution of mercuric chloride, and titrated with $N/10$ sodium hydroxide, the result enabling the amount of sulphur dioxide to be determined; sulphur trioxide is calculated by difference. Estimation of sulphur dioxide and trioxide in oleum is carried out in a similar manner.—W. J. W.

[Sulphuric acid;] Gaillard towers [for concentrating ——] and the electrical condensation of acid fumes. M. Kaltenbach. Chim. et Ind., 1921, **5**, 143—149.

The ordinary Gaillard tower system consists of the tower proper, which the hot gases enter at 850° C. and leave at 200°—220° C.; a small tower fed with weak acid from the scrubbers and acting as a recuperator, and the coke scrubbers. For satisfactory work the gas should leave the small tower at a temperature just above its saturation point, say 120°—130° C. Assuming that a true static equilibrium exists throughout the apparatus, the concentration of liquid acid in equilibrium with the vapour varies directly with the temperature. Though such a perfect equilibrium is not obtained, experiments are described to show that it is approached. No process can therefore at once give strong condensed acid and a complete condensation, and the function of the Cottrell process, which cannot affect the equilibrium between the liquid and gaseous phases, is limited to the aggregation of the vesicles of liquid formed at the moment of condensation. The author considers that rationally designed coke scrubbers can perform this more cheaply than electrostatic precipitators. A slightly lower acid content in the exit gases for the same temperature with the use of the Cottrell process is attributed to the oxidation of sulphur dioxide in the latter case by nitrous gases derived from incompletely denitrated acid. The author suggests the use of two small coke scrubbers each preceded by an efficient cooling coil and having a brick grid beneath which the gas enters, the coke increasing in fineness from bottom

to top, and with no heavy timbers to obstruct cooling. The first scrubber is to condense acid down to the lowest strength at which it can be economically concentrated, the product of the second being run to waste.—C. I.

Reaction $3HNO_2 \rightleftarrows 2NO+HNO_3+H_2O$; *Condition of an unattackable electrode in the* ——. A. Klemenc. Z. Elektrochem., 1921, 27, 110—112.

By comparing the observed with the thermodynamically calculated potentials, when a platinum electrode is in contact with the system nitric acid—nitrous acid—nitric oxide at equilibrium, it is shown that the reaction indicated is $NO+2H_2O \rightarrow 4H^{\cdot}+NO_3'$ in solutions about 3*N*, but in dilute solutions the reaction $NO+H_2O \rightarrow 2H^{\cdot}+NO_2'$ also comes into play (*cf.* Pick, J., 1920, 446 A). (*Cf.* J.C.S., Apr.)—E. H. R.

Phosphoric acid and soluble phosphates; Investigation of the U.S.P. assay for ——. A. E. Stearn, H. V. Farr, and N. P. Knowlton. J. Ind. Eng. Chem., 1921, 13, 220—225.

The U.S.P. method of determining phosphoric acid (neutralisation with sodium hydroxide, using phenolphthalein as indicator, precipitation with an excess of silver nitrate, neutralising the mixture with zinc oxide, and titrating the excess of silver) is untrustworthy except at one definite concentration, namely 6·2 mg. per c.c. The error is probably due to the formation of slightly soluble acid phosphates of silver, and the authors therefore recommend the following process, in which the phosphoric acid is first converted into the tri-sodium salt:—10 c.c. of a 1% solution of the sample is treated with 5 g. of sodium nitrate, cooled in an ice bath, and titrated with *N*/1 sodium hydroxide solution, using phenolphthalein as indicator. The number of c.c. of alkali required is divided by two, and this quantity is also added to the mixture. The latter is then treated with 50 c.c. of *N*/10 silver nitrate solution, diluted to 100 c.c., filtered, and the excess of silver titrated in an aliquot portion of the filtrate.—W. P. S.

Caustic soda; Preparation of —— *from sodium sulphate.* B. Neumann and E. Karwat. Z. Elektrochem., 1921, 27, 114—124.

To determine the course of the reaction between sodium sulphate and lime and the maximum yield of caustic soda to be expected, experiments were made at 15°, 40°, 70°, and 100° C. at different dilutions starting with sodium sulphate and lime on the one hand and calcium sulphate and sodium hydroxide on the other. To obtain a condition of equilibrium, continuous shaking for several days was necessary. The highest yield, 60%, was obtained at the lowest temperature, 15° C., and the greatest dilution, *N*/10, the corresponding yield at 100° C. being only 27%. The yield falls rapidly as the temperature or concentration is increased. On account of the high dilution required, the process is of no technical interest. A further drawback is that, during concentration, reaction takes place between the caustic soda and calcium sulphate, lime being precipitated with a corresponding loss of caustic soda. The yield is not increased by working under pressure.—E. H. R.

Potassium in silicates; Method for the determination of ——. J. J. Morgan. J. Ind. Eng. Chem., 1921, 13, 225—227.

About 0·5 g. of the silicate is decomposed with hydrofluoric acid, the mixture evaporated to dryness, the residue dissolved in 25 c.c. of 3*N* hydrochloric acid, an excess of 10% perchloric acid added, and the mixture evaporated until fumes of perchloric acid are evolved; the residue is treated with water and again evaporated with the addition of perchloric acid, and this is repeated until the residue dissolves completely in hot water. After a final evaporation, the residue is treated with 20 c.c. of 98% alcohol (containing 1 c.c. of 60% perchloric acid per 300 c.c.), stirred during 15 mins., the potassium perchlorate then collected on a filter, washed with the alcohol (using about 40 c.c.), dried at 130° C., and weighed. Calcium and sodium sulphates interfere, and if these salts are present, the sulphate must be determined in the weighed precipitate.—W. P. S.

Adsorption of alkali chlorides by animal charcoal. H. Hartleben. Biochem. Zeits., 1921, 115, 46—51.

All alkali chlorides are adsorbed by animal charcoal to the same extent within the limits of experimental error.—S. S. Z.

Potassium perchlorate; Preparation of ——. E. Blau and R. Weingand. Z. Elektrochem., 1921, 27, 1—10.

Potassium perchlorate is best prepared by heating potassium chlorate in a quartz flask at 480° C. without a catalyst for 8 hrs. In this way 69 g. of perchlorate can be obtained from 100 g. of chlorate. There is always about 3% of the chlorate undecomposed, but this is removed by a single crystallisation. Iron vessels are unsuited for this preparation. Potassium perchlorate can also be obtained by electrolysis of solutions of potassium chlorate between a nickel cathode and a platinum anode, using a current density of 0·15 amp. per sq. dm. The process suffers from the drawback that, even with a rapidly circulating electrolyte, the electrodes become incrusted with the sparingly soluble perchlorate. This difficulty is surmounted by electrolysing sodium chlorate and converting the very soluble sodium perchlorate into the potassium salt by treating with potassium chlorate, thus regenerating sodium chlorate which is used in the next electrolysis. At 27° C. the current yield of the process increases with increasing cathode current density, but a change in the anode current density has no effect on the yield. The electrolysis of barium chloride solution at 60° C. under the same conditions gives a current yield of 50—60% of barium perchlorate. (*Cf.* J.C.S. May.)—J. F. S.

Polysulphide-sulphur; Determination of ——. A. Wöber. Z. angew. Chem., 1921, 34, 73.

Ten c.c. of the diluted polysulphide solution is added to an excess of 10% sodium sulphite solution, the mixture heated at 50° C. for 15 mins., cooled, and the thiosulphate formed by the interaction of the polysulphide and the sulphite is determined as described by Bodnar (J., 1915, 1111). Allowance must be made for any thiosulphate present originally in the polysulphide solution, and if the latter contains alkali carbonate, the thiosulphate determinations must be made after the solution has been treated with cadmium acetate or zinc sulphate, and filtered.—W. P. S.

Chromic oxide; Carrying down of lime and magnesia by precipitates of ——. E. Toporescu. Comptes rend., 1921, 172, 600—602.

When chromium is precipitated by ammonia from solutions of its salts containing calcium or magnesium salts, the amounts of calcium or magnesium carried down increase with the concentration of their salts, and tend towards limits corresponding to the chromites, $Cr_2O_3,3CaO$ and $Cr_2O_3,3MgO$, respectively. The calcium or magnesium may be removed from such precipitates by washing them on the filter or by decantation with a boiling 5% solution of ammonium nitrate.—W. G.

Nitrogen; Cathodic reduction of dissolved elementary ——. E. Tiede and A. Schleede. Z. Elektrochem., 1921, 27, 112—114.

In 1807 Davy claimed to have obtained nitric acid and ammonia by the electrolysis of distilled water containing dissolved air, but Rayleigh failed to confirm this result. The authors have repeated the experiment under widely varying conditions, at pressures from atmospheric up to 150 atm., and have failed to obtain a trace of ammonia.—E. H. R.

Sulphur; Elastic ——. T. Iredale. Kolloid-Zeits., 1921, 28, 126—127.

Elastic sulphur is prepared by treating powdered sodium thiosulphate with one-half its weight of concentrated nitric acid, and after the reaction is complete, adding water and washing the product. A yellow elastic transparent mass is obtained which after distension to four times its length will regain its original form. Cooling to 0° C. makes it opaque and brittle, but heating in water to 100° C. reproduces the elastic characteristics. After 24 hrs. it passes completely into the crystalline form. —J. F. S.

Patents.

Oxides of nitrogen; Production of —— *and catalyser therefor.* General Chemical Co., Assees. of W. W. Scott. E.P. 136,158, 2.12.19. Conv., 7.9.18.

The catalyst consists of a mixture of cobaltic and aluminium oxides in the proportion of 100 pts. Co to 2·5—30·0 pts. Al. It is prepared by evaporating a solution of the nitrates and igniting the residue. The material is broken up, and fragments passing through an 8-mesh sieve but retained on a 20-mesh sieve are used. With an air-ammonia mixture of 8·3% NH_3 by vol., a conversion of 84·5% is obtained, or, if the catalyst is prepared at a temperature not exceeding 650° C., as high as 94%. The catalyst has a longer life and is less sensitive to dust than any other metallic oxide catalyst. It may also be used on a carrier, such as pumice. —C. I.

Alkali pentaborates; Preparation of —— *direct from boron ores.* A. A. Kelly and B. D. Jones. E.P. 158,992, 15.11.19.

Boron ores are mixed with sufficient alkali to ensure a proportion of 1 mol. of Na_2O or K_2O per 5 mols. of B_2O_3, and the mixture is calcined, and treated with carbon dioxide in presence of water, either under atmospheric or increased pressure. After concentration of the liquor, the alkali pentaborate is crystallised out.—W. J. W.

Aluminium oxide; Process of producing —— *from chloride of aluminium.* S. E. Sieurin. E.P. 159,086, 19.1.20.

Aluminous raw material is dissolved in hydrochloric acid, and the solution is saturated with hydrogen chloride, introduced at the top of the vessel. The acid mother liquor is then displaced from the precipitated crystals of aluminium chloride by forcing in a concentrated solution of aluminium chloride at the bottom of the vessel, after which this solution is separated from the crystals by centrifugal action, and the latter are calcined. The mother liquor may be used for solution of further raw material. To avoid accumulation of iron in the liquor, it is treated with hot sulphuric acid (sp. gr. 1·71), the gaseous hydrogen chloride evolved being utilised in the initial process; the sulphuric acid solution is concentrated and cooled, and the precipitated iron sulphate separated.—W. J. W.

Sulphurous acid; Process of and apparatus for the manufacture of liquid —— *from dilute sulphurous acid gas.* P. Pascal. E.P. 159,337, 2.12.19.

Dilute gas from pyrites or blende burners is compressed, cooled, and washed in a tower with carbolic oil of sp. gr. 1·0 obtained in the distillation of coal tar between 175° C. and 225° C. This absorbs one-fourth of its weight of sulphur dioxide at atmospheric temperature and pressure. The oil passes on through a heat interchanger and is distilled under reduced pressure, a plate column removing any oil driven over with the gas; the latter is subsequently liquefied by compression. —C. I.

Chromous chloride; Process of making ——. M. C. Taylor, Assr. to N. D. Baker. U.S.P. 1,369,204, 22.2.21. Appl., 15.12.19.

A solution of chromic chloride containing 1—2% of free hydrochloric acid is electrolysed in a cell having a diaphragm.—C. I.

Pickling solutions; Method of and apparatus for reclaiming spent ——. H. S. Marsh and R. S. Cochran. U.S.P. 1,369,451, 22.2.21. Appl., 9.1.20.

The salts in the hot solution are precipitated by cooling, heat being exchanged with a counter current of the cooled solution.—C. I.

Zinc chloride; Production of anhydrous ——. P. Danckwardt, Assr. to The Danckwardt Process Co. U.S.P. 1,369,729, 22.2.21. Appl., 23.10.19.

A mixture of aluminium chloride, carbon, and zinc ore is gradually heated, the zinc chloride formed being volatilised and condensed.—C. I.

Ammonium phosphate; Method of making ——. H. C. Hetherington and J. M. Braham, Assrs. to United States of America. U.S.P. 1,369,763, 22.2.21. Appl., 10.6.20.

Mono-ammonium phosphate is crystallised from slightly acid solution at a temperature above 105° C.—C. I.

Ammonium salts; Preparation of ——. Akt.-Ges. für Stickstoffdünger. G.P. (A) 299,141 and (B) 300,141, 5.7.16.

(A) Calcium cyanamide, which has previously been treated with carbon dioxide, is heated to temperatures above 100° C., under pressure, in presence of salts which decompose ammonium carbonate, such as those of the alkaline earths, and of water or steam. The process may be carried out in presence of catalysts, such as manganese dioxide and ferric hydroxide, which assist the formation of urea. (B) Dicyanodiamide, or a solution containing it obtained by treating crude calcium cyanamide with water, may be used as initial material.—W. J. W.

Potassium salts; Apparatus for effecting continuous solution of crude ——. G. Sauerbrey, Maschinenfabrik A.-G. G.P. 328,448, 6.2.20.

The apparatus consists of two rotary drums, placed one behind the other, and each provided with a partition mounted on a support which passes through both drums and is suspended from external brackets. Each drum is divided by the partition into two compartments, in which the solvent and the solid material move respectively in the same and in opposite directions.—W. J. W.

Alkali carbonates; Manufacture of —— from alkali sulphides and hydrosulphides. P. Beck. G.P. 329,832, 25.7.17.

ALKALI sulphides and hydrosulphides are converted into alkali carbonates by the action of magnesium bicarbonate, or of carbon dioxide in the presence of magnesium carbonate, oxide, or hydroxide, in aqueous solution.—L. A. C.

Potassium ferrocyanide; Manufacture of —— [from calcium cyanamide]. Strontian- und Potasche-Fabr. Rosslau, Zweigniederlassung der Dessauer Zucker-Raffinerie G.m.b.H. G.P. 330,194, 15.2.20.

A MIXTURE of, *e.g.*, 100 pts. of calcium cyanamide, 75 pts. of potassium carbonate, and 30 pts. of iron filings is heated to redness in the absence of air; the product is cooled, ground to a powder, and extracted with water.—L. A. C.

Cooling and washing tower for gas from pyrites kilns. O. Frohberg. G.P. 330,656, 30.12.19.

THE tower is built of acid-resisting ferro-concrete and is provided with a firebrick roof carrying the system of spraying tubes, each of which is attached separately to the roof, and all of which are connected with a central supply tube. The interior of the tower is filled with small glazed earthenware tubes, and a protective acid-resisting or impermeable sheath may be arranged, if necessary, round the inner walls.—A. R. P.

Alkali phosphate; Process for the preparation of ——. Chem. Fabr. Rhenania A.-G. G.P. 330,840, 4.2.17.

NATURALLY occurring phosphates, *e.g.*, vivianite or triplite, are heated with solid alkali carbonate to 700°—800° C. Extraction of the sintered mass with water yields a solution of alkali phosphate.

—A. R. P.

Lining for calcium cyanamide furnaces. G. Polysius. G.P. 330,943, 6.9.19.

THE furnace is lined with quartzite, cement, or concrete, with or without an admixture of cement clinker. No reaction takes place between the charge and the lining, nor does the charge stick to it.—A. R. P.

Arsenic and sulphur; Separate production of —— from sulphur ores containing arsenic. A. Wyporek, and Rheinisch-Nassauische Bergwerks- und Hütten-A.-G. G.P. 331,068, 7.8.19.

THE ore is heated rapidly to a high temperature, whereby the arsenic is volatilised with very little loss of sulphur, and the ore can then be roasted to produce gases from which sulphuric acid almost free from arsenic is obtained.—L. A. C.

Zinc oxide; Manufacture of ——. New Jersey Zinc Co., Assees. of J. A. Singmaster, F. G. Breyer, and A. E. Hall. E.P. 137,513, 24.11.19. Conv., 8.1.19.

VIII.—GLASS; CERAMICS.

Glass-house furnaces; Design and operation of ——. F. J. Denk. J. Amer. Ceram. Soc., 1921, 4, 224—236.

THE proper design of regenerator chambers is discussed and two inefficient designs are criticised. The gases being heated should move upwards, and those being cooled should pass downwards. The position of the ports should be selected carefully and losses by heat radiation minimised as much as possible. The reversing valve should be efficient and operated regularly, and the furnace should be fitted with thermo-couples and draught recorders. Analyses of the waste gases should be made frequently, and the operation of the furnace controlled accordingly.—H. S. H.

Glasses; Simple expansibility test for determining the welding properties of ——. D. E. Sharp. J. Amer. Ceram. Soc., 1921, 4, 219—223.

THE ends of two glass rods are heated and welded together by forceps and a thread pulled out with the two glasses forming opposite sides. If the glasses have different coefficients of expansion the strip bends into a curve, the glass of higher coefficient of expansion being on the inside of the curve. The coefficient of expansion can be determined, if standard glasses of known coefficient are available, by finding the glass with which the specimen will give a thread without curvature on cooling.—H. S. H.

Kaolinite; Study of the heating and cooling curves of Japanese ——. S. Satoh. J. Amer. Ceram. Soc., 1921, 4, 182—194.

HEATING and cooling curves up to 1400° C. were taken for Japanese kaolinite by means of a differential couple using quartz sand as standard. A heat absorption due to evaporation of moisture occurred up to 100° C., and was followed by a weak heat evolution from 100° C. to 300° C., possibly due to the oxidation of foreign materials. Heat was absorbed from 450° C. to 650° C. owing to dehydration, and a further endothermic change took place from 650° C. to 750° C., and was ascribed to the dissociation of kaolinite into free alumina and free silica. An exothermic reaction near 950° C. was considered to result from the polymerisation of alumina, while a heat evolution between 1200° and 1300° C. was ascribed to the formation of sillimanite from the dissociated free alumina and silica. The loss in weight on ignition occurred chiefly between 400° and 650° C., and the rate of increase per degree reached a maximum about 460° C. Changes in the microstructure of the kaolinite occurred at 600°, 900°—1000°, 1250°—1300°, and at 1400° C., when sillimanite began to develop. Heating and cooling curves for alumina prepared by calcining the nitrate, hydroxide, and sulphate gave exothermic reactions ascribed to the polymerisation of alumina at 800°—900° C. and at 1100°—1200° C., instead of at 950° and 1250° C., as in the case of kaolinite. In the discussion it was pointed out that some of the author's conclusions are erroneous, owing to his failure to recognise the endothermic change in quartz at 575° C.

—H. S. H.

Fire-brick made from ganister, flint clay, and plastic clay mixtures; Tests of ——, with special reference to spalling. R. M. Howe and M. Sheppard. J. Amer. Ceram. Soc., 1921, 4, 206—212.

HAND-MADE bricks were prepared from mixtures of

ganister, flint clay, and plastic clay so as to vary the silica content from 53 to 77% and the alumina content from 43 to 20%. The fusion points of the bricks decreased gradually as the silica content increased, and were usually about 2 cones lower than the fusion points of the corresponding pure alumina-silica mixtures. It was found that behaviour under load at high temperatures was not a function of chemical composition, but depended more on the temperature of burning. The resistance to spalling of each brick (as tested by alternate heating and dipping in cold water) decreased on burning at higher temperatures. The bricks with the highest silica content were most resistant to spalling at the lower burning temperatures, but this advantage was lost at 1400° C.—H. S. H.

Electrical porcelain; Effect of the replacement of free silica by alumina and zirconia in ——. R. Twells, jun., and C. C. Lin. J. Amer. Ceram. Soc., 1921, **4**, 195—205.

In order to test whether free silica is detrimental to the mechanical and dielectric strength of electrical porcelain, a series of sixteen batches was prepared in which various proportions of the free silica were replaced, weight for weight, by alumina, zirconia, or combinations of both, and bars and discs, after burning at cone 8½—9 or at cone 12, were tested for shrinkage, transverse strength, impact strength, heat resistance, porosity, and dye penetration. When zirconia replaces flint overburning of the porcelain occurs at a lower temperature, but the ability to withstand sudden temperature changes is greatly increased. The firing shrinkage is increased, the colour is poorer, while the transverse strength is highest with equal parts of zirconia and flint. The maturing temperature of the porcelain is greatly raised by replacing flint by calcined alumina, but the ability to withstand sudden temperature changes is greatly decreased. The firing shrinkage is also decreased, and a high transverse strength is developed when the body approaches vitrification. The presence of free silica increases the dielectric strength.—H. S. H.

Patents.

Dryer and kiln; Superposed ——. S. Kupfer, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,369,285, 22.2.21. Appl., 23.4.20.

A continuous dryer is provided above a continuous tunnel kiln, with its exit end adjacent the entrance end of the kiln. Cars carrying the ware move successively through the dryer and kiln.—H. S. H.

Tunnel kiln and method of operating same. P. d'H. Dressler, Assr. to American Dressler Tunnel Kilns, Inc. U.S.P. 1,369,330, 22.2.21. Appl., 26.2.20.

The atmosphere formed by a hot body of gas in a central portion of the kiln is maintained without substantial movement except for convection currents. Gas is blown into the end of the kiln along the top of the kiln chamber so as to create a downward flow of the kiln atmosphere between the end and centre of the kiln, with a return flow along the bottom of the kiln to the kiln end where the excess gas escapes. The maintenance of an unduly high top temperature in the end of the kiln by reason of the convection current circulation of the kiln atmosphere is prevented.—H. S. H.

Ceramic ware; Process for preheating and smoking —— in ring furnaces. G. Korngiebel. G.P. 331,677, 19.7.17.

The chambers of the preheater are separated from one another by dampers which do not reach to the bottom of the combustion flue. The smoke and gases are removed through slits in the bed of the hearth, while the steam rises up through the chambers and is thereby separated from and prevented from saturating with moisture the cooled smoke and from flowing from heated to cooler chambers, and so being repeatedly condensed and evaporated.—A. R. P.

Refractory insulating material; Manufacture of —— from aluminium and alkali silicates and combustible fillers. L. Kern. G.P. 330,064, 11.5.19.

The mixture of silicates and filling material is worked to a paste with a solution of aluminium hydroxide in a dilute mineral acid, and yields on calcining a product of high porosity.—L. A. C.

Glass-pot furnace. M. Mathy. U.S.P. 1,369,453, 22.2.21. Appl., 26.6.19.

See E.P. 135,115 of 1919; J., 1920, 25 A.

Retorts for burning ceramic ware. G.P. 332,131. See X.

IX.—BUILDING MATERIALS.

Agglomerant; Special ferriferous —— and its applications in presence of puzzuolanic materials. F. Ferrari. Giorn. Chim. Ind. Appl., 1921, **3**, 53—56. (*Cf.* J., 1920, 821 A; 1921, 11 A.)

Portland cement in which the sesquioxides are present in the proportions of their equivalents, although exhibiting all the qualities of cements of this type, should be free from binary compounds of aluminium and iron. Making use of a mixture composed of limestone (87·6% $CaCO_3$), clay, silicious sand, and ferric oxide obtained by burning pyrites, the author has obtained a cement of the percentage composition: SiO_2, 24·04; insoluble silicious residue, 0·28; Al_2O_3, 3·32; Fe_2O_3, 5·24; CaO, 65·10; MgO, 0·47; SO_3, 0·61; alkali (not determined), 0·94. Such cement is stable towards sulphates and chlorides and is to be regarded as a product of more easy scorification and of a greater content in hydraulites (calcium silicates). It is capable of replacing, in all their applications, not only iron-Portland cement, but also ordinary Portland cement. Addition to such cements of puzzuolanic substances so as to modify their high basicity, renders them suitable for giving absolutely impermeable mortars, which are of general application and are mechanically superior to those having a basis of ordinary Portland cement.—T. H. P.

Blast-furnace slag, and its use as building material. R. Grün. Z. angew. Chem., 1921, **34**, 101—102.

The composition of blast-furnace slag varies between wide limits. It may contain 24—70% SiO_2+MnO, 3—30% Al_2O_3+Fe_2O_3, and 17—60% CaO+MgO. For use as a hydraulic cement, finely ground slag is first calcined with limestone, and the resulting "Portland cement clinker" is mixed with granulated slag in the proportions of 15:85. Another composition, known as "iron Portland cement," consists of 30% of slag and 70% of the clinker. Even slags, hitherto considered worthless, have been rendered suitable by the addition of lime and alumina, and heating the mixture in an electric furnace, but there remains a wide field for further investigation.—W. J. W.

Insulating and building materials; Relative heat conductivities of some ——. J. J. Lichtin. Chem. and Met. Eng., 1921, **24**, 388.

The relative heat conductivity of "Porete" (an insulating material made from cement and sand), and of various other materials, was determined by

the "air box" method. Cubical boxes, 8×8×8 in., with walls 1 in. thick, were heated internally by an electric incandescence lamp. Temperatures were observed by means of two thermometers inserted through the walls, and three thermometer bulbs in contact with the outer surface of the box. The values for the conductivity expressed as the quantity of heat in B.Th.U. which flows through 1 sq. ft. of area, through a unit thickness of 1 ft., having a temperature difference of 1° F. between its faces, were as follows, the specific gravities of the various materials being given within brackets:—Concrete, 1 cement : 2 sand (2·01), 0·1760; gypsum board (1·00), 0·0846; "Porete" reinforced with expanded metal (0·98), 0·0786; yellow pine from N. Carolina (0·64), 0·0719; air cell asbestos board (0·21), 0·0335; cork board (0·187), 0·0277. The values apply only under similar conditions of experiment, which are approximately those under which the materials are used ordinarily as insulators or building materials. —C. A. K.

Patents.

Bricks, blocks, slabs, tiles, etc.; Manufacture of —— for paving or building or other purposes. C. M. C. Hughes, A. E. Brown, and T. Hill-Jones, Ltd. E.P. 159,239, 13.9.19.

Bricks etc. are prepared by grinding and mixing together clinker or slag (60 pts.), limestone dust (27 pts.), bitumen (10 pts.), making the mass plastic by the addition of creosote oil (3 pts.) and if necessary water or sodium silicate solution, and pressing the bricks etc. from the plastic mass. They are dried and then heated sufficiently to flux the bitumen, which binds the material on cooling. In order to prevent clogging of the pistons of the press, it is sometimes necessary to mix and heat the bitumen, oil, and limestone together and, after cooling, to grind this binder finely before mixing with the main body as described above.—H. S. H.

Heat non-conducting compositions. J. C. S. McLay. E.P. 159,411, 28.2.20.

A mixture of 75% of waste calcium carbonate from the manufacture of soap, 20% of sawdust, 5% of flour sweepings added as an agglutinating material, and 5% of ammonium carbonate is heated in the plastic condition, when the ammonium carbonate acts as an aerating agent.—H. S. H.

Artificial [lithographic] stone. J. Kiermayer, and Ver. Chem. Fabr. zu Leopoldshall, A.-G. G.P. 329,592, 26.6.19.

A stone free from air bubbles is prepared without treatment under vacuum, by mixing magnesia with an excess of magnesium chloride solution, stirring to release air bubbles, and then removing the excess solution.—L. A. C.

Lime; Manufacture of volume-stable, dry ——. J. Joachim and J. Schulte. G.P. 329,943, 21.2.19.

Quicklime is slaked in open vessels by means of superheated steam, and either before or during the process is heated above 100° C.—L. A. C.

Concrete; Process for the preparation of a —— free from shrinkage cracks. A. Guttmann. G.P. 330,784, 29.1.20.

So much plaster, or other material which acts in a similar manner, is intimately mixed with the finely ground cement or cement mixture that the natural contraction of the cement on setting is counterbalanced or exceeded by the expansion due to the added material.—A. R. P.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cast iron; Manufacture of —— from burnt pyrites in the electric furnace. M. Guédras. Giorn. Chim. Ind. Appl., 1921, 3, 58—61.

In the Guédras and Duina process, the burnt pyrites is first completely dried, then almost completely freed from sulphur, and agglomerated, in a continuous rotary furnace of the Breuillé type heated by lignite gas or blast-furnace gas; in this way the percentage of sulphur is reduced from 2—3 to 0·1—0·2, and the resulting product is hard yet highly permeable to gases. The burnt pyrites is then introduced into the fusion hearth of an electric furnace, where it undergoes reduction and further desulphurisation, the latter being facilitated by addition of dry calcium chloride: $FeS+CaCl_2+CO=Fe+CaS+COCl_2$; the carbonyl chloride liberated is rapidly decomposed, by means of moist air, into hydrogen chloride and carbon dioxide. The percentage of sulphur in the cast iron obtained is 0·01—0·03.—T. H. P.

Steel; Dimensional limitation of successive heat-treatments of carbon ——. W. P. Wood. Chem. and Met. Eng., 1921, 24, 345—356.

Uniform samples, 1 cm. square and 10 cm. long, of steel bars ranging in carbon content from 0·11 to 1·14%, were measured in a micrometer, and subjected to a hardening quench in oil from 900° C., followed by a draw at 600° C., in order to bring all possible effects to a maximum value. After the first complete heat treatment the hypo-eutectoid steels were shorter than in the original annealed state, the eutectoid steels had not changed appreciably in length, and the hyper-eutectoid steels showed slight dilatation. The results in general are held to be in agreement with the view of Andrew and others (J., 1920, 452 A), according to which two opposing influences affect carbon steels which are heated slowly to 1000° C., namely, a contraction caused by the conversion from α- to γ-iron, and a solution of carbide which causes an expansion.—C. A. K.

Steels; Distribution of hardness in quenched carbon —— and quenching cracks. K. Honda and S. Idei. Sci. Rep. Tohoku Imp. Univ., 1920, 9, 491—507.

To study further the formation of quenching cracks in carbon steels (*cf.* Honda and Matsushita, J., 1919, 582 A), experiments were made to determine the distribution of hardness in quenched specimens in the form of small cubes or cylinders, by means of Shore's scleroscope. With a soft quenching, for example in oil from a temperature not exceeding 820° C., the hardness decreases from the periphery to the centre. With moderately hard quenching, for example a 0·91% C steel in water from 780° C. or a 1·47% C steel in oil from 900° C., the hardness of the specimen is uniform. A hard-quenched steel, for instance a 0·68% C steel quenched in water from 800° C. or above, is hardest towards the centre. This is explained by the presence of arrested austenite in martensite (*cf.* Honda, J., 1919, 821 A). The quenching cracks in small pieces occur when the hardness of the central portion is greater than that of the periphery, the cause being the stresses occasioned by the difference between the specific volumes of austenite and martensite. Since this difference increases as the temperature falls, the cracking usually takes place as the specimen approaches room temperature. The hardness of a hard-quenched specimen gradually increases with lapse of time owing to gradual transformation of the arrested austenite into martensite. To avoid cracking, quenching should be only medium hard. The temperature from which to quench a particular

steel can be determined by quenching specimens from, say, 800°, 900°, and 1000° C. in oil and determining the hardness at the centre and periphery. Hardness-quenching temperature curves are drawn for the centre and periphery, and the point of intersection of these will give the temperature from which to quench to obtain uniform hardness throughout the specimen.—E. H. R.

Steel and iron; Mechanism of increased corrosion of —— due to small copper contents. D. M. Buck. Trans. Amer. Electro-Chem. Soc., 1921, 47-54. [Advance copy.]

PRELIMINARY results of a four-years' test on the rate of corrosion of copper steels are given after atmospheric exposure of specimens for 32 months. The specimens contained from 0·01 to 0·242% Cu, and the amount of rusting was estimated by determining the quantities of the loose film removable by brushing with a wire brush, and the closely adherent film removed later by an ammoniacal solution of ammonium citrate. A steel containing 0·1% Cu showed a loss of 3·62 oz. per sq. ft. due to loosely adherent rust, and of 6·43 oz. due to closely adherent rust, which was the minimum total loss of the series. Present data indicate that the harmful influence of sulphur on corrosion is in some manner controlled by the addition of copper, and also that the more adherent nature of the rust film formed is related to the increased resistance peculiar to copper steels.—C. A. K.

Corrosion of old iron. E. A. and L. T. Richardson. Trans. Amer. Electro-Chem. Soc., 1921, 55—58. [Advance copy.]

ANALYSES of fifteen specimens of iron and steel which had resisted atmospheric corrosion for upwards of 30 years show that steels which are rust-resisting contain copper. Steels containing more than 0·1% Cu were relatively in good condition; those containing less than 0·1% Cu gave contradictory evidence. A comparative test of exposure for two years showed that the older irons are no less subject to corrosion under similar conditions than recently manufactured wrought iron. —C. A. K.

Iron and steel; Preventing corrosion of —— when not exposed directly to the atmosphere. F. N. Speller. Trans. Amer. Electro-Chem. Soc., 1921, 37—46. [Advance copy.]

EXPERIMENTS and observation in practical working have shown that the extent of corrosion of iron or steel in contact with water is directly proportional to the quantity of oxygen in solution, and that the composition of the iron is of minor account. Dissolved oxygen has been removed economically by mechanical de-aeration of the water. For practical protection of water pipes from internal corrosion at 80° C. it is not necessary to have the oxygen less than 0·4 c.c. per l., but for steam boiler work a limit of 0·2 c.c. per l. is advisable. This limit may be reached by spraying the water into a vacuum chamber, or by passing the water through a suitably designed preheater. A second method is based on fixing the free oxygen by chemical combination and has been employed in practice by passing the heated water through a storage tank packed with a mass of expanded iron giving about 60—70 sq. ft. of surface per cb. ft. of space. In 30 mins. at 77° C. the oxygen content may be reduced to 0·3 c.c. per l. Free carbon dioxide, or bicarbonate, is always increased slightly by this treatment, but practically no corrosion is found to occur in the absence of oxygen. Other metals, *e.g.* zinc, may be used but are more costly. A series of experiments shows that the corrosion of zinc and brass is retarded greatly by the removal of oxygen from water, and also that the accelerating effect of copper and brass in contact with steel is reduced by the lack of a depolariser. The rate of corrosion may be retarded by increasing the proportion of hydroxyl ions in relation to the hydrogen ions present in the water, as by addition of lime or soda ash, but the formation of an insulating scale may cause other difficulties. The results of recent research on the corrosion of hot water feed service piping are tabulated.—C. A. K.

Ferro-silicon; Influence of silicon upon the properties of ——. A. T. Lowzow. Tidskr. Kemi, 1919, **16**, [1]. Chem. and Met. Eng., 1921, **24**, 481—484.

A SERIES of commercial alloys containing from 49·1% to 93·41% Si were examined by microscopical and chemical means, and from the results obtained the equilibrium diagram was constructed. The compound FeSi forms an eutectic with silicon at 55% Si and 45% Fe. The compound $FeSi_2$ is a decomposition product formed from the eutectic by slow cooling. Determinations of the specific gravities of the various alloys indicate that a fairly accurate estimation of the silicon content can be quickly obtained by determining the specific gravity, although slight variations are produced by the introduction of impurities.—J. W. D.

Ferronickels; Effect of additions on the anomaly of dilatation of ——: application to iron-nickel-chromium alloys. P. Chevenard. Comptes rend., 1921, 172, 594—596.

THE curve showing the variation of the total anomaly of dilatation, A_0, with nickel content in the case of pure ferronickels, rises rapidly from zero at 25% Ni to reach a sharp maximum at a point corresponding to the compound Fe_2Ni, and then descends, crossing the zero line at 58% Ni, reaching a minimum, and then recrossing at 80% Ni, and finally recrossing at 99% Ni after a second slight maximum. By the addition of increasing amounts of chromium similar curves are obtained, but the maximum value of A_0 becomes less and less, and the maximum point is displaced more and more towards a higher nickel content. The maximum points are practically on a line which, starting from Fe_2Ni, tends towards a point on the line NiCr. —W. G.

Iron pyrites; Heat of dissociation of ——. H. Kamura. Chem. and Met. Eng., 1921, **24**, 437.

IRON pyrites was decomposed at different temperatures ranging from 400° to 700° C., the decomposition pressure at which the sulphur vapour was given off being measured. From the decomposition pressure curve the heat absorbed in the decomposition was deduced thermodynamically, giving, Q, the heat of decomposition per molecular volume of sulphur vapour formed as 37,223 cals., corresponding to the heat value of the equation $2FeS_2 = 2FeS + S_2$. The value of the heat absorbed per atom of sulphur, or conversely the heat evolved in the combination, can therefore be expressed thermochemically as (FeS,S gas) = 18,611 cals.—J. W. D.

Gold ore; Treatment of antimonial —— at the Globe and Phœnix Gold Mine, S. Rhodesia. V. E. Robinson. J. Chem. Met. Min. Soc. S. Afr., 1921, **21**, 117—119.

THE greater part of the coarse stibnite present in the ore is separated by hand picking, and the remainder of the ore is wet crushed by stamps, the pulp from which passes over amalgamated plates to a series of grinding pans containing mercury. The pan discharge passes over canvas strakes, then through a series of mercury traps, and finally into a classifier to separate the sands and slimes, which are stored separately and allowed to weather for some time, after which each is cyanided separately.

The concentrates from the strakes are reconcentrated and amalgamated in a pebble mill. The recoveries are 65—70% by amalgamation, and about 80% of the total gold in the tailings is recovered by cyaniding. The amalgam and the precipitate from the sand plant both contain small amounts of antimony, which is removed from the crude bullion by melting it under an oxidising flux, skimming, and then directing a blast of dry compressed air on the surface of the molten metal until no further fumes are evolved. The bullion obtained from the slimes contains a large amount of copper; it is granulated, mixed with sulphur and slowly heated in a graphite pot, when most of the base metals and some silver enter the matte and a slightly antimonial bullion is obtained, which is further purified as described above.—A. R. P.

De-aeration of water or [cyanide] solutions; Chemical methods of ——. H. A. White. J. Chem. Met. Soc. S. Afr., 1920, **21**, 105—111

For removing oxygen from cyanide solutions before precipitation of gold, and from boiler-feed water, comparative tests were made with a ferrous salt, a manganous salt, and tannin. The sample of water or cyanide solution was treated with the calculated quantity of chemical, together with lime, the mixture shaken, and allowed to stand until next day. The clear liquid was siphoned off and analysed, and the result compared with an analysis of the original sample. With tannin the dissolved oxygen was removed, and there was no reaction with the cyanides present. With ferrous ammonium sulphate all the oxygen was removed, but there was a loss of half the cyanide. Manganese sulphate removed only 77% of the oxygen; there was no loss of cyanide. Wattle bark and dried extract of the bark were also efficient, but required an alkalinity of at least 0·008% of soda. Wattle bark extract was the cheapest of the compounds tested. A few experiments were made on the effect of dissolved oxygen in boiler water on the corrosion of iron. In some cases the oxygen was partly removed with wattle extract and by passing hydrogen through, and in these cases the amount of iron dissolved, when free in the water or in contact with carbon, was very much less than in the untreated water.—J. H. J.

Gold; Quantitative determination of —— by cupellation, and the examination of large quantities of gold destined for the manufacture of coinage. J. W. A. H. Smit. Rec. Trav. Chim., 1921, **40**, 119—152.

In the cupellation of gold bullion certain details must be strictly adhered to if accurate results are to be obtained. Uniformity of access of air in the furnace is necessary and too rapid a cupellation is injurious. The surface and porosity of the cupel are not of such importance as its thermal conductivity. The ratio of lead to copper must be at least 55:1 and may be higher. Heating of the button after iridescence is necessary for commercial samples of gold, and in this case the best ratio of silver to gold is 2:1. The cornets should be well heated both before and after boiling with acid, and it is advisable to roll the buttons into sheets 0·15 mm. thick. The nitric acid used for the extraction must be absolutely free from chlorine and of a somewhat higher concentration (36° B., sp. gr. 1·33) than that generally used.—W. G.

Zinc dust and scrap; Electro-metallurgical process for working up —— to the pure metal. H. Paweck. Z. Elektrochem., 1921, **27**, 16—21.

In working up brass for copper by an oxidation process large quantities of zinc dust are obtained. This dust is worked up as follows: The mass is treated with a slight excess of dilute sulphuric acid, filtered, the solution treated with zinc scrap to precipitate copper, filtered, and treated with the calculated quantity of bleaching powder to oxidise and precipitate iron. The solution is then used to make the anolyte and catholyte for the subsquent electrolysis. The electrolysis is carried out in a two-diaphragm cell, the cathode part being between the two anode parts and between the two diaphragms. The anodes are lead plates, 3·35 sq. dm. surface, and the cathode an iron plate. The anolyte contains 4% of zinc and 5% of free sulphuric acid, whilst the catholyte is neutral and contains 10% of zinc. The electrolysis is carried out with a current of about 4·1 amps. and 5·5 initial voltage which falls to 3·65 volts in 19 hrs. The process is stopped when the zinc concentration has fallen to 4%; at the same time the acid content of the catholyte has risen to 5% and that of the anolyte to 10%. The catholyte is used in the next operation as anolyte and the original anolyte is treated with more zinc dust and used as catholyte. By this process 1 kg. of zinc is obtained for the expenditure of 3·38 k.w.-hrs.; this corresponds to a current yield of 99·08%. A similar process for working up the worn out zincs of batteries is described; in this the zincs are placed in the anode cell and used as the anode.—J. F. S.

Lead; Electrolytic corrosion of —— by continuous and periodic currents. E. R. Shepard. Trans. Amer. Electro-Chem. Soc., 1921, 23—36. [Advance copy.]

The rate of corrosion of lead submerged under water and in moist earth was determined under the influence of continuous and periodically reversed currents, with a view to amplify the work of McCollum and Ahlborn (U.S. Bur. of Standards. Tech. paper No. 72). The results agree generally with those of the earlier work, except that a coefficient of corrosion of 100% (equal to the theoretical value) may be obtained in earth with very low direct current densities (0·93 amp. per sq. ft.). The earth must be saturated with water and pressed firmly around the specimen in order to obtain this value. The time factor does not apparently influence the coefficient of corrosion of lead in earth, but in water a reduction occurs from 100% after 20 hrs. to 65% at 90 hrs. With periodically reversed currents having an algebraic average of zero, the coefficient, calculated on the basis of anodic current, decreases rapidly in earth, reaching a value of 14% after 465 hrs. Under alternating conditions the low coefficients of corrosion obtained are due probably to a re-deposition of lead during the cathodic period, or an equivalent reduction process at the cathode. When the positive and negative values are unequal, the coefficient increases with the percentage of the total ampère-hrs. under anodic conditions.—C. A. K.

Nickel. W. von Selve. Z. Metallk., 1921, **13**, 40—46.

A general account of the degree of purity and physical properties of the commercial forms of nickel, and a brief outline of the technical applications of the metal.—E. H. R.

Chromium; Cause of periodic phenomena in the electrolysis of chromic acid and the deposition of metallic ——. E. Liebreich. Z. Elektrochem., 1921, **27**, 94—110.

When a solution of chromic acid is electrolysed, using iron, chromium, or platinum electrodes, regular periodic, sudden variations of both the P.D. and of the current are sometimes observed, in such a manner that as the P.D. increases the current falls slightly, and *vice versâ*. A study of the P.D.-current density curves of a chromic acid cell over a range of P.D. from 1 to 7 volts, using a 22% solution of chromic acid and platinum electrodes,

showed three breaks in the curve, and, in effect, it is shown that the chromic acid solution has four characteristic P.D.-current density curves above 1·7 volts, all approximately parallel. Each curve corresponds with a specific electrolytic chemical reaction. Over certain ranges of current density two or more of these reactions are possible, each requiring a specific P.D., and the periodic variations of P.D. and current observed are due to the periodic sudden change of the course of the electrolysis from one reaction to another. On the first two curves, no hydrogen is evolved from the cathode but a slight deposit is formed of chromi-chromate. On the third curve there is a slight cathodic deposit of a different kind and some evolution of hydrogen, whilst on the fourth curve there is vigorous evolution of hydrogen and metallic chromium is deposited on the cathode. The chemical reactions characteristic of the four curves are probably of the types: (1) $Cr^{vi}\rightarrow Cr^{iii}$; (2) $2CrO_3+6H^{\cdot}\rightarrow Cr_2O_3+3H_2O$; (3) $Cr_2O_3+2H^{\cdot}\rightarrow 2CrO+H_2O$; (4) $2H^{\cdot}\rightarrow H_2$ and $CrO+2H^{\cdot}\rightarrow Cr+H_2O$. When iron or chromium cathodes are used, metal passes into solution except on curve (4). Generally deposition of metallic chromium only occurs with a current density of at least 0·5 amp. per sq. cm., but under certain conditions solutions can be obtained which give a chromium deposit at a much lower current density, for instance by heating chromic acid crystals below the incandescent point so as to cause them to dissolve in their water of crystallisation and then diluting with water. Such a solution has an abnormally low conductivity and gives a firmly adhering, brilliant deposit of metallic chromium, instead of the usual grey, loosely adhering deposit. A similar result was obtained by dissolving in water and electrolysing the chromo-chromate deposit obtained from the electrolysis characteristic of curve (3) above. Alkali chromite solutions, obtained by adding potassium hydroxide to a solution of chrome alum, also deposit adherent metallic chromium at a low current density.
—E. H. R.

Chromite; Iodometric method for determining chromium in ——. E. Little and J. Costa. J. Ind. Eng. Chem., 1921, **13**, 228—230.

A MIXTURE of 0·4 g. of chromite and 5 g. of sodium peroxide is heated in an iron crucible for 5 mins., then fused for 15 mins., cooled, and dissolved in 150 c.c. of water; the solution is treated with a further 0·5 g. of peroxide, boiled to destroy the excess of the latter, cooled, and hydrochloric acid added until all ferric hydroxide has dissolved. 5 c.c. of concentrated hydrochloric acid is then added for each 100 c.c. of solution, an excess of ammonium fluoride is introduced, the mixture is treated with 3 g. of potassium iodide and, after 3 mins., the liberated iodine is titrated with standard thiosulphate solution.—W. P. S.

Blast-furnace slag. Grün. *See* IX.

Tungsten. Fiorentino. *See* XXIII.

PATENTS.

Ferro-chrome alloys; Production of ——. W. B. Ballantine. E.P. 159,280, 15.11 and 5.12.19.

THE special alloy constituents, *e.g.*, tungsten and vanadium, are added to the steel bath as ferro-alloys in compacted form either as briquettes or in canisters, and contain in their compact mass a thermo-reducing mixture made up of a compound of a metal desired in the alloy, *e.g.*, chromite, and a thermo-reducing agent such as aluminium. The thermo-reducing mixture is added in such proportion that on ignition in the molten bath the mixture liberates sufficient heat to maintain the bath at the temperature necessary to ensure complete reaction of all the constituents.—J. W. D.

Magnetic or weakly magnetic iron ore containing magnetic ferrous sulphide as a secondary constituent; Process and apparatus for treating ——. R. Stören and R. Johanson. E.P. 159,380, 18.12.19.

THE ore is subjected to a reducing treatment with hydrogen at 400°—500° C. in a continuously working furnace, whereby the oxide content is partially reduced while the sulphide constituents are rendered permanently non-magnetic. The material leaving the reducing furnace is suspended in water and subjected to magnetic separation, the separated oxide being conveyed to a second reducing furnace and reduced to metal, which is transferred to an electric melting furnace.—J. W. D.

Ferrosilicon-aluminium; Production of ——. W. B. D. Penniman and R. S. White. U.S.P. 1,369,298, 22.2.21. Appl., 9.6.19.

COMPOUNDS of aluminium, silicon, and iron are treated with a reducing agent in an electric furnace whereby a ferro-silicon-aluminium alloy is produced.—J. W. D.

Steel; Non-magnetic forgeable ——. F. Krupp, A.-G. G.P. 298,429, 13.11.15.

THE steel contains 10—15% Ni, 6—4% Mn, and 5—2% Cr. The chromium may be replaced partly or completely by tungsten, molybdenum, or vanadium.—L. A. C.

Iron; Separation of other metals from ——. Koelsch. G.P. 330,131, 7.5.14.

IRON may be separated from other metals, *e.g.*, stripped of a plating of copper or nickel, by treating the mixed metals with a solution containing an excess of nitrite ions and a low concentration of hydrogen ions. The process, however, is not applicable to the detinning of iron.—A. R. P.

Silico-ferromanganese or silicospiegel; Production of —— *in the blast furnace.* C. Stöckmann, sen. G.P. 330,196, 25.2.19.

IN order to minimise the loss of manganese when making silicospiegel the charge is so made up that the oxygen content of the bases (Al_2O_3+CaO+MgO) in the resulting slag is as great as, or greater than, that of the silica, by the addition, if necessary, of sand or quartz to the charge, which addition also serves to reduce the alumina content of the slag if that is too high.—A. R. P.

Zinc and iron; Recovery of —— *from zinciferous iron ores by smelting in the blast furnace.* F. Burgers. G.P. 330,396, 8.5.19.

ZINCIFEROUS iron ores and roasted sulphide products containing up to 50% Zn are smelted in a metal-jacketed blast furnace lined with carbonaceous bricks, whereby the zinc is volatilised and subsequently recovered from the issuing gases.
—A. R. P.

Metals [ductile tungsten] and their manufacture. British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 155,851, 17.4.17.

A MIXTURE of 1400 g. of commercial tungstic acid, 620 g. of sodium carbonate, 620 g. of potassium carbonate, and 300 g. of sodium nitrate is made into a paste with water, dried, and fused. The melt is dissolved in water, the solution filtered and diluted to 6 l., giving solution A. A mixture of 180 g. of commercial silicic acid, 620 g. of potassium carbonate, and 150 g. of sodium nitrate treated in a similar manner gives solution B. 250 c.c. of B is added to 3 l. of A, the mixture boiled and poured into 3 l. of a boiling solution of hydrochloric acid (1:1). The precipitate is filtered off, washed with water till the washings come through turbid, dried, ignited, and reduced by hydrogen in 100-g. lots.

This metal ("X metal") can be pressed, sintered, and drawn into wire, but better results are obtained by grinding equal weights of it and the oxide from which it was produced and reducing the mixture in hydrogen in 150-g. lots. In the above process the silica may be replaced by tantalum or columbium pentoxides. An alternative process is to reduce the residue obtained by evaporating tungstic acid with boric acid solution or, preferably, to mix 1 kg. of the tungstic acid precipitate produced in the first process with 12·5 g. of boric acid in 500 c.c. of water, dry, ignite, and reduce the residue. The powder produced by the last process ("Z metal") is blacker and more bulky than that produced by the former processes. In all cases the metal obtained is very pure, of a fine-grained structure, and when drawn into wire does not sag at high temperatures. Filaments prepared from the wire are given a preliminary heat treatment by running them at 30 volts for 2 min., then at steps of 5 volts for 2 min. up to 60 volts, finally at 15% over-voltage for 15 mins.—A. R. P.

Tungsten ores; Process and apparatus for the treatment of ——. J. C. Blanch. G.P. 330,987, 28.3.20.

The ore, after decomposition with alkali chloride and, if necessary, nitrate, is roasted, and the resulting mass is treated with dilute sulphuric acid in a vessel in the form of an inverted conical funnel through which steam is passed in such a manner that the solids are vigorously agitated. The resulting solution of the bases in the ore with tungstic acid in suspension is delivered by tilting the funnel-shaped vessel into a series of decanting vessels in cascade, in which vessels the tungstic acid is recovered by settling and decantation, and is subsequently reduced to metal.—A. R. P.

Tin; Recovery of —— from tin-pot skimmings, with zinc chloride as a by-product. A. J. and H. D. Evans. E.P. 158,926, 23.9.19.

Tin-pot skimmings are ground with a slag-forming mixture (glass 3 pts., felspar 1, fluorspar 1 pt.) to a thin paste containing flattened pieces of tin. After draining and washing on a filter cloth the liquor may be evaporated for the recovery of zinc chloride and the residue smelted with addition of soda ash. The slag produced during smelting may be used in the preliminary grinding process.
—C. A. K.

Tin; Winning of ——. J. J. Collins. E.P. 159,071, 10.12.19.

Tin-bearing rock is crushed, treated with reducing gases to convert tin oxide into metallic tin, and then subjected to the action of chlorine gas, preferably obtained by the expansion of anhydrous liquid chlorine. The stannic chloride formed is evaporated or extracted by means of solvents, and metallic tin is recovered by replacement of the tin by zinc.—C. A. K.

Aluminium alloys. J. E. Hurst and E. B. Ball. E.P. 159,008, 18.11.19 and 5.3.20.

Light aluminium alloys containing 0·5—6% Cr, and not more than 6% of additional elements, such as Cu, Ni, Zn, Mg, Sb, are suitable for castings which are subjected to high temperatures, *e.g.*, parts of internal combustion engines. It is preferred that the total percentage of additional elements does not exceed the chromium content.
—C. A. K.

Ores and the like; Treatment of —— by flotation. M. T. Taylor and J. W. Partington. E.P. 159,025, 21.11.19.

In the flotation treatment of ores, particularly for the separation of tin and tungsten, the flotation agent may be sulphonated fatty or resin acid, which may be dissolved in a fatty acid ester, *e.g.*, propyl, butyl, or amyl acetate, or in a cyclic compound containing nitrogen, *e.g.*, pyridine. Phenolic substances, or other oils used in flotation practice, may also be added.—C. A. K.

Metallic surfaces; [Electrolytic] cleaning of ——. T. A. Edison. U.S.P. 1,369,271, 22.2.21. Appl., 3.7.19.

Metals are cleaned in an electrolytic cell using as an electrolyte a solution of an alkali sulphate and sodium or potassium hydroxide.—J. W. D.

Cinnabar ore; Apparatus for treating ——. A. J. Garver. U.S.P. 1,369,738, 22.2.21. Appl., 26.12.19.

The apparatus comprises a rotary condenser, a device for directing gas and fumes from a retort into the condenser, and a water-discharge pipe communicating with this device.—J. W. D.

Manganese-copper alloys; Ferruginous ——. Isabellenhütte, G.m.b.H. G.P. 303,864, 4.2.17.

Manganese-copper alloys containing also, if required, other metals, such as zinc, tin, or aluminium, are treated with a certain amount of silicon, perferably as ferro-silicon. The resulting alloy, when molten, runs more freely, and on cooling no segregation of constituents rich in iron occurs.—A. R. P.

Metals; Process and furnace for recovering —— from their ores by smelting. H. Dahlem. G.P. 330,290, 13.6.19.

Heat is supplied to the furnace by passing a mixture of compressed air and gas through a series of tuyères situated one above the other, so that each zone of the furnace can be independently heated to the required temperature. Means are provided for regulating the air supply so as to obtain the maximum utilisation of the heat.—A. R. P.

Metals and alloys; Process for coating substances having a large surface with ——. Chem. Fabr. von Heyden A.-G. G.P. 330,306, 21.5.20.

The metal or alloy is disintegrated by an electrical method in a suspension in a suitable liquid, *e.g.*, water, alcohol, ether, or oils, of the substance to be coated, if necessary, after the addition of a reducing agent. For example, nickel is disintegrated under a 1% aqueous solution of hydrazine hydrate containing bole in suspension.—A. R. P.

Metallic oxides; Reduction of —— by means of sodium alloys. W. Schuen, H. C. Grosspeter, and A. Kemper. G.P. 330,679, 20.2.17.

Metallic oxides, *e.g.*, those of manganese or chromium, are reduced to the corresponding metal by heating them with finely divided alloys of sodium with one or more of the metals—iron, manganese, or silicon, preferably NaSi, on the hearth of a Siemens-Martin furnace or in other suitable apparatus. These sodium alloys may also be used for deoxidising molten metals such as iron or steel.
—A. R. P.

Regenerative furnace for refining copper, brass, and other alloys. F. Weeren. G.P. 307,704, 31.8.17.

The hearth of the furnace is connected by means of two different interchangeable heads, on each side of the furnace, with two independent chamber systems, in one of which the air is preheated and in the other the gas. This process avoids the difficulty experienced in carrying out the refining in regenerative furnaces of the ordinary type, due to large quantities of oxides being deposited in contact with the chequerwork of the regenerators.
—A. R. P.

Roasting furnace for pyrites, spent oxide, or the like; Rotary ——. Rocholl. G.P. 332,130, 27.7.19. Addn. to 326,441 (J., 1921, 183 A).

The interior of the front part of the cells is made conical, and the discharge openings for the roasting gases are arranged in an axial direction from these conical ends. This arrangement allows the charge to pass rapidly from the radial charging channels into the roasting chambers and prevents it from falling back into the channels during rotation. The gases also are still more readily removed from the apparatus than by the previous arrangement.
—A. R. P.

Metals; Process for rendering the surfaces of ——. *more highly resistant to attack.* R. Walter. G.P. 330,707, 11.3.17.

The metal to be treated is coated with a relatively thin layer of a more highly resistant metal in the liquid state, and welding of the two metals is effected by electrical or thermal methods. As coating metals, alloys of iron or chromium, or of metals of the iron and chromium groups with copper and, preferably, metals such as vanadium or titanium, used in alloy steels, are suitable, *e.g.*, alloys consisting of 60% Fe, 30% Cr, and 10% Ni, or of 70% Fe, 15% W, 10% Ni, and 5% Cu, have a high mechanical strength and resistance to oxidation.—A. R. P.

Copper, zinc, and silver; Process for sulphatising sulphide ores and products containing ——. *Process for producing metallic oxides and sulphur dioxide from solutions of metallic sulphates.* W. Buddeus. G.P. (A) 331,176, 27.11.19, and (B) 331,177, 12.11.19.

(A) The finely powdered ore is mixed with solutions of salts of very difficultly fusible oxides, and the mixture, after being made into briquettes and dried in a shaft furnace, is roasted. In this way sintering of the charge is avoided, and owing to the porous nature of the charge the air is enabled to come into contact with every particle of it, thus preventing "kernel" roasting. (B) Concentrated solutions of zinc sulphate, or of other metallic sulphates, such as those of magnesium or copper, are mixed with a finely divided carbonaceous fuel and the mixture is rapidly dried in thin layers on rolls. The dried mixture is smelted, after the addition of more fuel, if necessary, in a blast furnace or converter by means of compressed air, or it may be heated in a retort or other suitable furnace after briquetting. The sulphur dioxide evolved is used for making sulphuric acid, while the oxide obtained in the case of zinc is very dense and suitable for use directly in the distillation process as it is practically free from sulphur.—A. R. P.

Zinc; Diagonal retorts for the distillation of —— *or for the burning of ceramic ware or the like.* H. V. Dahlem. G.P. 332,131, 12.7.19.

The material to be treated is prevented from coming in contact with the walls of the retort by enclosing it in a specially constructed receptacle which fits into the retort and can be readily replaced when the operation is finished. These receptacles are rounded on the front side to prevent their sticking in the retorts, and are provided with a channel on the under-side, so that by pushing a rod under them they can easily be lifted up in case of accident.

Patents.

Insulating and protecting electrical apparatus; Compositions for —— *and for other purposes.* The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 159,421, 17.3.20.

A composition which can be baked at relatively high temperatures without blistering, is made by dissolving a resin, such as shellac, copal, or rosin, in an aqueous solution of ammonia and mixing with an alkali silicate. A filler, such as silex, and a colouring matter, such as ultramarine blue, may be added.
—J. S. G. T.

Electric furnace. M. R. Trembour, Assr. to Ludlum Electric Furnace Corp. U.S.P. 1,369,578, 22.2.21. Appl., 1.10.19.

An electric furnace comprises a hearth upon which the charge rests, top electrodes some of which are maintained in arcing relation to the charge during operation of the furnace, and an electrical connexion to the marginal area of the hearth.
—J. S. G. T.

Fixation of gases; Electric ——. G. T. Southgate. U.S.P. 1,369,714, 22.2.21. Appl., 11.4.18.

The gases are delivered through porous electrodes arranged within the reaction chamber and connected with conductors extending outside the chamber. Gas induction tubes are connected with

the electrodes, and the reaction chamber is provided with a tube for conveying away the products of reaction.—J. S. G. T.

Electric flaming arc; Process and apparatus for treating gases in the ——. E. Kneip. G.P. 330,079, 7.9.19.

THE electrodes between which the arc is struck are in the form of endless bands, cables, or chains, flexible tubes, etc., of metal, alloy, or other conducting material. The electrodes are supported upon conductors in such manner that the distance between them increases after the manner of the horns of a lightning arrester.—J. S. G. T.

Electro-osmosis; Diaphragm for ——. A. Nathansohn. G.P. 329,720, 12.10.19.

THE diaphragms are composed of metallic peroxides, such as lead dioxide, manganese dioxide, either alone or mixed with binding material. Such diaphragms are suitable for use in the electro-osmosis of mixtures of albumin and ammonium sulphate, *e.g.*, serum preparations.—J. S. G. T.

Electrodes composed of carbon and powdered pyrolusite; Compressed positive —— *for galvanic cells.* F. Christ. G.P. 329,726, 4.7.19.

THE texture of the electrodes is so adjusted either by means of external pressure or by choice of the degree of granulation of the powder, that the size of the pores in the electrodes increases gradually towards the interior, whereby the deposition of deleterious particles, *e.g.*, crystals of ammonium salts, upon the surface of the electrodes is prevented, owing to the velocity of diffusion being greater at the surface of the electrode than towards the interior thereof.—J. S. G. T.

Storage battery; Electric ——. H. Bardt. G.P. 329,787, 19.11.19.

A SOLUTION of a perchlorate is used as electrolyte, in conjunction with electrodes of indifferent metals. Thus a solution of lead perchlorate or copper perchlorate may be used, and the positive electrode, disposed horizontally at the bottom of the cell, is covered with the amount of lead oxide corresponding with the amount of metal deposited from the electrolyte during the charging process, which converts the lead oxide into lead peroxide.
—J. S. G. T.

Electrodes of large cross-sectional area; Production of ——. Ges. für Teerverwertung m.b.H. G.P. 329,904, 28.11.19.

A NUMBER of smaller electrodes are combined so as to form one electrode of the desired cross-sectional area, and this is consolidated by baking in a furnace.—J. S. G. T.

XII.—FATS; OILS; WAXES.

Oil-bearing and textile plants; Development of albumin and oil in the seeds of ——. Kleberger. Chem. Umschau, 1921, 28, 2—5.

THE albumin and oil content of the seeds of rape, poppy, flax, hemp, and cameline (German sesame) were determined in the green, yellow (fully grown), and fully ripened stages, the experiments being carried over a period of four years. The highest content of nitrogenous substances was found in the green stage, diminishing in the subsequent stages of ripening. In the yellow stage the nitrogen is mainly present in the non-albuminoid condition and as amides, etc., true albuminoids, however, preponderating in the fully ripe stage. In the green stage, the "fatty substances" consist chiefly of resins and waxy substances, and exist in relatively small proportion. As the seeds develop to the fully ripe stage, the proportion of true fats increases at the expense of the resins and waxes. Hempseed shows an exceptional behaviour in being nearly at its full state of development of albumin and fat in its yellow-ripe stage. From experiments carried out by storing seeds collected in their different stages of ripeness for a period of two months, it was shown that the maximum yield of oil and albumin is obtained by harvesting the seeds in the fully ripe stage, loss of water resulting without any other corresponding changes taking place.—A. de W.

Herring oil; Composition of ——. C. Grimme. Chem. Umschau, 1921, 28, 17—19.

THE proximate analysis of a sample of herring oil fatty acids gave the following figures: saturated fatty acids, 20%; oleic acid, 20%; linolic acid, 33%; linolenic acid, 17%; clupanodonic acid, 9%. The saturated fatty acids were determined by the lead salt-ether method, whilst clupanodonic acid was separated as octobromide from the accompanying linolenic acid hexabromide precipitated in an ether and acetic acid solution, by extraction of the mixed bromides with hot benzene. Linolic acid tetrabromide was separated from oleic acid dibromide by solution of the latter with petroleum ether of low boiling-point from the residue left on evaporation of the filtrate from the octo- and hexabromides. The author does not consider the existence of Tsujimoto's highly unsaturated acid, $C_{22}H_{34}O_2$ (J., 1920, 825 A), to be proved.—A. de W.

Otoba butter; An analysis of ——. W. F. Baughman, G. S. Jamieson, and D. H. Brauns. J. Amer. Chem. Soc., 1921, 43, 199—204.

A SAMPLE of otoba butter from the fruit of *Myristica otoba*, had sp. gr. 0·9293 at 20°/20° C.; n_D^{40}=1·4710; iodine value (Hanus), 54·0; saponif. value, 185·0; m.p., 34·0° C., and contained 9·3% of essential oil; unsaponifiable matter (other than essential oil), 20·4%; fatty acids, 67·6%. The essential oil consisted chiefly of sesquiterpenes; the fatty acids of myristic acid and to a lesser extent lauric acid, with a trace of palmitic acid and a little oleic acid. In addition to otobite the authors isolated another compound iso-otobite from the unsaponifiable matter.—W. G.

Annatto in fats and oils; Test for ——. W. Brinsmaid. J. Ind. Eng. Chem., 1921, 13, 216—217.

FIFTEEN g. of the melted and filtered fat is shaken with 15 c.c. of chloroform and 15 c.c. of 5% sodium hydroxide solution, and the mixture then heated at 50°—60° C. until the emulsion is broken up; the soap froth is transferred to a beaker, 10 c.c. of water, 2 c.c. of the sodium hydroxide solution, and a small quantity of paper pulp are added, the mixture is heated on a steam-bath for 30 mins.,

and the pulp then collected in a Gooch crucible. As soon as the liquid has passed through, the pulp is treated with a few drops of stannous chloride solution; if annatto is present a pink coloration is obtained.—W. P. S.

Cottonseed oil; Catalytic hydrogenation of ——. L. Kahlenberg and G. J. Ritter. J. Phys. Chem., 1921, **25**, 89—114.

Laboratory experiments indicate that of the common single metal catalysts, nickel is the most efficient, cobalt and iron possessing reduced activity in the order named. A 50% nickel-cobalt catalyst is more active than either metal used alone, but iron-cobalt and iron-copper possess little activity. Zinc catalysts prepared by reduction of the carbonate show some activity as also does a catalyst prepared from zinc carbonate precipitated in the presence of aluminium powder. Zinc and powdered charcoal, and zinc and pumice are not such good catalysts as zinc alone, and aluminium, zinc-aluminium prepared from zinc nitrate, and granulated zinc show no catalytic activity. On the other hand, "replaced" nickel obtained by the action of pure granulated zinc on nickel chloride solution and also nickel obtained by reduction of powdered nickel chloride with hydrogen are good catalysts, showing optimum activity of 180° C. A bismuth-charcoal catalyst is fairly active.—A. de W.

Unsaturated fatty acids; Products of autoxidation of ——. W. Fahrion. Chem. Umschau, 1921, **28**, 5—7, 20—21.

A simplified modification of Hazura's method for the detection of linolic acid in oils is given as follows: 10 g. of the fat is oxidised in the usual way with 10 g. of potassium permanganate, the alkaline solution acidified, and the separated oxidation products boiled with 1 l. of water. Any dihydroxystearic acid is filtered off from the hot liquid, the filtrate made weakly alkaline, concentrated to 100—150 c.c., and extracted with ether after acidification with hydrochloric acid. Azelaic acid, together with any unoxidised fatty acids, pass into the ethereal solution, any sativic (tetrahydroxystearic) acid floating as white flocculi in the intermediate layer. On examining cottonseed oil by this method, 10 g. of the oil gave 0·6 g. of an ether-insoluble residue, which on recrystallisation yielded white silky needles of m.p. 152° C., having an elementary composition corresponding to tetrahydroxy-stearic acid. Neither tallow nor mowrah fat contains linolic acid, but a fair amount is indicated as being present in lard. Goldschmidt and Weiss (Chem. Umschau, 1917, 158) have worked out a method for the evaluation of "fatty acids suitable for soap-making" in oxidised oils, by determining the difference between the proportion of fatty acids soluble in ether and those insoluble in petroleum spirit of high boiling-point. The oxidised acids from fish oils, however, are often to a great degree insoluble in ether. The author points out that in consequence of the partial insolubility of oxidised fatty acids in water, a further yield of these acids is obtained by extraction of the evaporation residue from the aqueous acid layer after the acidification of the soap solution. Examination of this residue insoluble in ether led to negative results for the presence of glycerin, which is thus assumed to have been volatilised during analysis or decomposed by acid. On examination of a sample of linseed oil linoxyn (sp. gr. 0·973) the following results were obtained: Hehner value, 82·9; solid oxyacids (+ glycerin?), 7·0; liquid oxyacids (by extraction of evaporated acid aqueous layer with ether), 4·6; volatile fatty acids, 4·1; moisture, 2·5; ash, 0·5. On fractionating the acids soluble in petroleum ether by the lead salt-ether method and allowing for the increase in weight due to oxidation of the oil, 6·7% of saturated fatty acids of iodine value 12·0, were calculated on the original (unoxidised) linseed oil, a figure in substantial agreement with commonly observed values.—A. de W.

Bird-lime; Composition of ——. Y. Nishizawa. Tokyo Kwagaku Kwai Shi (J. Tokyo Chem. Soc.), 1920, **41**, 1043—1048. (*Cf.* Divers and Kawakita, Chem. Soc. Trans., 1888, 268.)

From the saponification products of bird-lime, obtained by heating with alcoholic caustic soda for 10 days on the water bath, palmitic acid and elaidic acid were isolated.—K. K.

Coconut oil; Determination of —— *in soaps by the Polenske method.* R. Jungkunz. Seifensieder-Zeit., 1920, **47**, 927—929, 949—951. Chem. Zentr., 1921, **92**, II., 418—419.

A knowledge of the Polenske value determined under proper conditions renders possible the determination of the coconut oil content of soap; difficulty is encountered, however, in distinguishing between coconut oil and palm-kernel oil. After the estimation of the fatty-acid content, sufficient soap to yield 4·75 g. of fatty acid is heated with 20 g. of glycerin and 1 c.c. of sodium hydroxide solution (1:1) over a small flame for about 10 min. until the mixture no longer froths greatly; after cooling to 80°—90° C., 90 c.c. of water, 50 c.c. of dilute sulphuric acid, and about 0·6 g. of coarse pumice stone are added, the subsequent distillation and further procedure being as usual.—D. F. T.

Soaps; Ultramicroscopic structure of ——. W. F. Darke, J. W. McBain, and C. S. Salmon. Proc. Roy. Soc., 1921, **A 98**, 395—409.

Curds of sodium soap consist of a felt of hydrated fibres, enmeshing and in equilibrium with a soap sol or gel of definite concentration, the solubility rising rapidly with temperature. The individual fibres may be many centimetres long, but they are barely of microscopic diameter. Potassium soap solutions on cooling first develop fibres which are similar to those of sodium soaps, except that they are only a few hundredths of a millimetre in length and have a strong tendency to form twins. The stable condition at ordinary temperature is, however, the formation of innumerable tiny lamellar crystals of hydrated soap. The hydrogen soap, cetylsulphonic acid, is similar to the potassium soaps, but the particles of colloidal cetylsulphonic acid are very much more prominent.—J. F. S.

Saponification; Time factor in ——. P. J. Fryer. Analyst, 1921, **46**, 87—90.

As measured by the amount of alkali removed from the reacting solution, the velocity of saponification of fats and oils is in inverse ratio to the molecular weights of the fatty acids of the glycerides; in terms of the weight of fat or oil used, the velocity of saponification under the same conditions appears to be the same for all glycerides and probably for all esters. The velocity is influenced considerably by small differences of temperature, is increased by an increase in the concentration of the alkali, and also increases in direct proportion the molecular weight of the solvent used.—W. P. S.

Oil, fat and the like; Recovering and utilising solvent from the air which passes away from apparatus for extracting —— *by means of a solvent.* J. W. Melton and C. Downs. E.P. 159,039, 29.11.19.

The mixture of air and vapour leaving the con-

denser or dephlegmator of the apparatus passes into the top of a chamber containing a supply of unextracted material supported on a tray with a perforated bottom. The material absorbs the solvent from the mixture, and when it is almost saturated the supply of gases is diverted to another similar chamber. The material in the first chamber is discharged at the bottom and conveyed to the extraction plant.—L. A. C.

Hydrogenating catalysts; Preparation of ——. C. Ellis. U.S.P. 1,369,013, 22.2.21. Appl., 5.4.16.

A MIXTURE of oil and a substantially non-catalytic reducible nickel compound is subjected to the action of a gaseous reducing agent.—A. de W.

Copra; Recovery of oil from ——. C. O. Phillips. U.S.P. 1,369,265, 22.2.21. Appl., 17.5.19.

GROUND copra is intimately mixed with a small amount of a dilute alkaline solution and subjected to a heating and pressing operation.—A. de W.

Soap. C. S. Townsend. E.P. 159,083, 7.1.20.

A TOILET soap contains from 5 to 20% of the solids obtained by evaporating the waste whey derived from cheese factories.—L. A. C.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Radio-active luminous pigments; Loss of activity of ——. G. Berndt. Z. tech. Phys., 1920, 1, 102—107. Chem. Zentr., 1920, 91, IV., 717.

EXPERIMENTS conducted with a series of radio-active pigments composed of zinc sulphide containing 0·2—0·02 mg. radium per grm., showed that the loss of activity after 9 months agreed with Rutherford's formula,

$$I_t/I_0 = 1/(A.t).(1-e^{-At}),$$

where I_0 is the original activity and I_t the activity after time, t, whilst A is a constant the value of which depends upon the experimental conditions. It was found, however, that the variations of the values for A with the radium content are more correctly represented by a hyperbola than by a straight line. Loss of activity is slower in the case of pigments prepared by diluting a highly active preparation with dry Sidot blende than in the case of pigments of equal activity prepared directly from a mixture of zinc sulphide and an aqueous radium solution. Pigments of which the activity is due to mesothorium and radiothorium depreciate to about the same extent as those containing radium. On the other hand, loss of activity from radiothorium preparations is more rapid.—W. J. W.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber; Solubility of crystalline substances in ——. G. Bruni. Giorn. Chim. Ind. Appl., 1921, 3, 51—53.

IN experiments on acceleration of vulcanisation by means of azobenzene, the author found that admixture of 10% of the latter with rubber yields a transparent, orange-red jelly, which gradually becomes opaque owing to deposition of crystalline azobenzene. Thermal analysis of the binary systems formed by rubber (freed from resin) with azobenzene, naphthalene, and *p*-toluidine shows that the rubber acts towards the crystalline constituent as an ordinary solvent, forming true saturated solutions; supercooling and supersaturation readily occur. The colloidal character of rubber plays no part in these phenomena. The marked concavity towards the concentration axis of the curves connecting temperature and composition indicates the formation of complexes between the rubber and the crystalline components of the systems. Prolonged heating of the systems produces no permanent alteration in the molecular state of the rubber, which behaves quite normally when subsequently separated from the crystalline compounds. —T. H. P.

PATENTS.

India-rubber; Compositions containing ——. W. H. Perkin, J. H. Mandleberg, and J. Mandleberg & Co. E.P. 159,014, 18.11.19.

RUBBER material is rendered non-inflammable by incorporating with it a large proportion of hydrated aluminium oxide. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 125,622; J., 1919, 409 A.)—D. F. T.

Rubber; Treatment of raw —— *when freshly coagulated from the latex.* S. C. Davidson. E.P. 159,106, 19.4.20. Addn. to 151,344 (J., 1920, 757 A).

THE pin plate, fitted with a relatively small number of pins for the perforation of the rubber, is made capable of up-and-down movement, whilst the frame carrying the layer of rubber synchronously moves forward with each upward movement of the plate; in this way a fresh portion of the surface becomes perforated at each stroke until the whole has been treated.—D. F. T.

Rubber goods; Ingredients for soft and hard ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 303,224, 3.10.16.

THE oily or resinous products obtained by the condensation of halogen derivatives of alkylbenzenes, in which the halogen atom is present in the side-chain, with naphthalene and its derivatives or with

coal tar oils or their individual hydrocarbon constituents, can be used with advantage in compounded raw rubber which is difficult to manipulate on account of its "dryness" or which yields hard or brittle products on vulcanisation.—D. F. T.

Rubber; Production of materials resembling ——. H. O. Traun's Forschungslaboratorium G.m.b.H. G.P. 329,593, 1.11.18.

Butadiene, homologous or analogous substances, mixtures of these, or products of their incomplete polymerisation are subjected to a pressure of 50—600 atm. at the ordinary temperature, the presence of a solvent or of a polymerisation catalyst being optional. With butadiene itself under a nitrogen pressure of 300 atm. the formation of butadiene-rubber is complete in about 4 weeks, whilst with a pressure of 600 atm. the period is only 5—6 days.—D. F. T.

Vulcanised rubber; Process for devulcanising ——. C. F. Willard. E.P. 159,987, 9.12.19.

Treating leather. U.S.P. 1,369,240. *See* XV.

XV.—LEATHER; BONE; HORN; GLUE.

Gallotannic acid; Extraction of ——. E. Knape. Chem.-Zeit., 1921, **45**, 239—241.

Galls are swollen with water, ground, and extracted with ether or ether and alcohol for 20—30 mins. in a cylindrical shaker fitted with an agitator. The extract is filtered off and three more extractions made. A clearer, brighter solution is obtained in this way than from dry powdered galls, and less solvent is required. Saturating the solvent with water and using this for the extraction of powdered dry galls is not so successful. The ether may be replaced by trichloroethylene or dichloroethylene with equally good results.—D. W.

[*Tannin analysis.*] *Comparison of the international filter-tube method and the official hide-powder method.* H. W. Wiley and W. H. Krug. J. Amer. Leather Chem. Assoc., 1920, **15**, 51—53.

Samples of valonia, mimosa bark, oakwood, chestnut, mimosa, and quebracho extracts were analysed by the filter-tube method in England and by the official method in America. The results were compared and show good agreement for moisture and "reds" except with the quebracho extract, where the filter-tube method gives higher results. In every case except one, the filter-tube method gives lower values for non-tannins than the official method and correspondingly higher values for tannin.—D. W.

Sole leather. Sole and upper leathers for army boots. C. Schiaparelli. J. Soc. Leather Trades Chem., 1921, **5**, 44—56.

The normal hygroscopicity of sole leathers is about 4%, but the presence of hygroscopic substances, *e.g.*, glucose, may increase it to 7—8%. The rigidity of the leather can be determined by cutting samples of standard length and thickness, clamping one end, and noting the depression caused by weighting the other end with a standard weight. The amount of water-soluble matter as determined by the Koch extractor is not comparable with the results of actual wear. Tests should be made by immersing whole soles in water for 72 hrs., and results show that there seem to be three kinds of water-soluble matter in unadulterated sole leathers, viz., an easily soluble portion, a less easily soluble part, and 3% of difficultly soluble matter extracted only in the Koch extractor. The permeability is determined by immersing weighed portions of leather in water for 24 hrs., then re-weighing and adding to the increase the weight of the soluble matter extracted by the water during immersion. The purer the tannage and the less the natural soluble matter the leather contains, the more easily is it penetrated by water. The permeability is an inverse function of the percentage of water-soluble matter. There are two kinds of sole leather, viz., leather of the English type or valonia-tanned leather, with high content of water-soluble matter for damp, cold climates, and leather with a low content of water-soluble matter for hot dry climates. —D. W.

Patents.

Leather; Method of treating ——. S. O. Hahn, Assr. to The Chrome Leather and Rubber Tyre Co. U.S.P. 1,369,240, 22.2.21. Appl., 16.2.20.

A portion of the sulphur is removed from ordinary commercial rubber cement, the product is forced into the leather beyond the surface, and the impregnated leather is subsequently united to a rubber layer by vulcanisation.—D. W.

Drying solutions. G.P. 331,142. *See* I.

XVI.—SOILS; FERTILISERS.

Soils; Degree of temperature to which —— *can be cooled without freezing.* G. Bouyoucos. J. Agric. Res., 1920, **20**, 267—269.

A column of wet soil was placed in a freezing point tube, the bulb of a Beckmann thermometer inserted into the soil, and the tube placed in mixtures at different low temperatures until a temperature was found at which the soil froze spontaneously. All mineral soils could be cooled to $-4{\cdot}2°$ C. and kept at that temperature indefinitely without freezing. Agitation of the soil however caused it to freeze at once. The amount of water in the soil made no difference. Peat and "muck" could be supercooled to $-5°$ C. Some other materials, such as silica, carbon black, and gelatin, saturated with water, were tested also, and these could be cooled to $-6°$ C. without freezing. The experiments show that in winter when the temperature of the soil falls only a few degrees below zero, the soil does not really freeze. —J. H. J.

Soil; Effect of various crops upon the water extract of a typical silty clay loam ——. G. R. Stewart and J. C. Martin. J. Agric. Res., 1921, **20**, 663—667. (*Cf.* J., 1918, 252 A.)

The effect of crops of maize, horse beans, potatoes, turnips, and barley upon the water extract of a loam soil was studied throughout the growing season. All the crops reduced the concentration of the water extract of the soil during the height of the growing season, as judged by the change in electrical conductivity of the extract. In another series of experiments, the concentration of the soil solution was determined in the neighbourhood of the plant roots and in a part of the same ground without plants. The observations were made by the method of freezing point determinations. No movement of solution towards the plants was observed, and no change in concentration occurred in the unplanted soil until the plant roots reached that area. —J. H. J.

Potassium; Concentration of —— *in orthoclase solutions not a measure of its availability to wheat seedlings.* J. F. Breazeale and L. J. Briggs. J. Agric. Res., 1921, **20**, 615—621.

Finely ground orthoclase containing 12·5% K_2O was shaken with distilled water, and germinated wheat seeds were floated on the surface of the mixture. The liquid contained 2—9 pts. of dissolved potash per million pts. The amount of potash in a

hundred seedlings after 2—3 weeks' growth was determined and was compared with controls in solutions free from potash. The results showed that the seedlings did not absorb any potassium from the solutions, although from potassium chloride solutions of the same concentration absorption took place readily. Addition of lime, gypsum, and carbon dioxide to the solutions did not render the potassium available, nor did boiling the solution. On the other hand, from a solution which had been filtered and oxidised by evaporation with acid, large amounts of potash were absorbed by the plant, and similar results were obtained with solutions which had been filtered through a Pasteur-Chamberland filter to remove colloids and then oxidised. The potassium in orthoclase thus appears to be combined in a complex form which is soluble in water, but is not available for plant use. The inference is drawn that the concentration of a plant food in a soil solution is not necessarily the measure of its availability to the plant.—J. H. J.

Soluble phosphate in superphosphate; Conditions affecting the reversion of ——. B. Neumann and K. Kleylein. Z. angew. Chem., 1921, 34, 77—80, 84—86.

In an examination of the influence of various reversion agents, preliminary experiments were carried out with pure monocalcium phosphate and phosphoric acid. Excess of calcium sulphate, or the presence of unconverted tricalcium phosphate, even at normal temperature, is instrumental in promoting decomposition of the soluble phosphate. If iron and aluminium exist as sulphates, their reverting action is not appreciable. Thus, after addition of these two sulphates, even up to 16%, to monocalcium phosphate, the total soluble phosphate found was 89·28% and 99·68%, respectively, and the loss with phosphoric acid was still less. On the other hand, considerable reversion occurs if the oxides of these metals are present in sufficient excess to escape conversion into sulphate. An addition to monocalcium phosphate of 4% of iron oxide reduced the soluble phosphate to 81·82%, and in the case of aluminium oxide, to 78·56%; with 16% of these oxides, the amounts of soluble phosphate were only 47·75% and 51·15%, respectively. The action is less marked with phosphoric acid, and its presence in superphosphate therefore to some extent mitigates loss of soluble phosphate. In commercial superphosphates, the effect of adding excess of sulphuric acid, in order to convert ferric oxide into sulphate, only partially achieves its object, an increased yield of about 4·5% of soluble phosphate being obtained with an increase of 12% of acid, and the presence of free acid in the resultant superphosphate renders the use of a large excess of acid undesirable. If the raw material contains more than 2% of ferric oxide, it is preferable to mix it with phosphates of smaller iron content. Aluminium compounds in commercial phosphates have no influence on the yield of soluble phosphate; the aluminium phosphate which is formed appears to be retained in a soluble condition by the free acid which is present.—W. J. W.

Patents.

Cheese manufacture; Treatment of whey produced in ——, *and production therefrom of nitrogenous matter suitable for use as a fertiliser.* J. Tavroges, J. W. Roche, and G. Martin. E.P. 158,816, 22.7.20.

The waste whey is heated to about 70° C. and agitated, the albumin present is then precipitated by addition of bleaching powder (about 0·002%), and the precipitate is collected and mixed with quicklime.—J. H. L.

Boiling and drying organic substances; Apparatus for ——. K. Niessen. E.P. 137,841 and 137,844, 13.1.20. Conv., 20.7.16 and 12.5.17. Addns. to 137,828.

See G.P. 319,335-6; J., 1920, 498 A.

Urea; Compound of ——. [*Fertiliser.*] C. Bosch, Assr. to The Chemical Foundation, Inc. U.S.P. 1,369,383, 22.2.21. Appl., 27.4.16.

See G.P. 295,548 of 1915; J., 1917, 560.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Suggestions on the production of a better raw ——. S. S. Peck. Int. Sugar J., 1921, 23, 158—161.

By the use of screens of relatively large mesh for straining the raw juice, a greater or less amount of very fine particles of cane fibre (*bagacillo* or "cush-cush") is permitted to pass through, so that during the subsequent operations of liming and heating the gum content becomes increased, owing to the solution of the pentosans and lignin, of which the fibre is largely composed. Although the gum content of the juice is normally small (viz., 2—5% of the sucrose present), its influence is important, particularly in retarding the boiling, crystallising, and centrifuging of the low-grade products. The use of a 100-mesh screen for the separation of the greatest amount possible of *bagacillo* from the raw juice previous to clarification is recommended.
—J. P. O.

Sugars; Deterioration of —— *in storage.* N. Kopeloff, H. Z. E. Perkins, and C. J. Welcome. J. Agric. Res., 1921, 20, 637—653. (*Cf.* J., 1920, 380 A, 523 A, 553 A.)

A large number of bags of raw sugar was examined chemically and bacteriologically at intervals of 4 weeks under ordinary conditions of storage. The period of observation was 8 weeks and there was found to be a loss in polarisation in most samples with a gain in reducing sugar and an increase in moisture. The number of bacteria and moulds increased in most cases, the numbers being greatest in those samples which suffered most deterioration. A large initial infection led to the greatest deterioration. When the number of organisms present was below 200 per g. and the moisture ratio was low, then the deterioration was either greatly reduced or prevented altogether.—J. H. J.

Decolorising carbons [*for sugar refining*]; *Comparative value of* ——. F. E. Thomas. Int. Sugar J., 1921, 23, 162—165.

A standard method of testing decolorising carbons for use in sugar manufacture and refining is recommended, and it is pointed out that the colour remaining in the treated liquid is of greater importance than that removed, and that different carbons adsorb the several colouring matters in varying degree. In carrying out the test, raw sugar liquor at 50° Brix, having a slightly acid reaction, is mixed in the cold with the sample of carbon (about 5% of the sugar present), raised to boiling point, and filtered, a standard carbon (preferably "Norit," owing to its great uniformity of efficiency) being treated under exactly the same conditions. An error is produced when observing the degree of colour in the Lovibond tintometer if the untreated and treated solutions are read in cells of different size, *e.g.*, ¼" and ½" respectively, as is frequently done.—J. P. O.

Sucrose; An inherent error in certain modifications of the Clerget method of determining —— *by double polarisation.* C. A. Browne. Int. Sugar J., 1921, 23, 166—167.

In the so-called neutral method of double polarisa-

tion employed by Jackson and Gillis (J., 1920, 634 A), the influence of sodium chloride, ammonium chloride, etc., upon the rotation of the invert sugar, and of amino-acids and other optically-active non-sugars, will depend, not only upon the amount of salt present in 100 c.c. of solution, but also upon the amount of water and sugar in the solution. Thus, solutions containing 52, 26, and 13 g. of sucrose in 100 c.c., polarised 99·00°, 99·35°, and 99·50° (calculated to 26 g.), though the amount of sodium chloride, viz., 2·315 g., present in each was the same. Similar results were obtained in the case of ammonium chloride, thus demonstrating that as the amount of sucrose in 100 c.c. diminishes, and the corresponding amount of water increases, the action of the dissolved salt upon the rotation of the sugar becomes correspondingly less, and the values approach 100. Therefore the fixed values of sucrose +2·315 g. NaCl=99·38, and +3·392 g. NH_4Cl= 99·43, employed by Jackson and Gillis as the positive constituents in their evaluation of the Clerget divisor, are true only for a concentration of 26 g. of sucrose in 100 c.c.—J. P. O.

Maize sugar. P. Vieillard. Bull. Agr. Inst. Sci. de Saigon, 1920, 2, 106. J. Inst. Brew., 1921, 27, 126.

The stem of the maize plant normally contains no sucrose and very little dextrose, but if the ears are removed when the grain begins to be milky, sugars accumulate in the stem. In a series of experiments the stems were investigated at various periods (7—34 days) after removal of the ears. The stems freed from leaves yielded 36—48% of juice, as compared with 80% in the case of the sugar cane, but the "bagasse" contained much sugar extractable by suitable means. The total extractable sugar in the stems amounted to 7—10% of sucrose and 1—3% of dextrose. Owing to the large proportion of dextrose and non-sugars not more than one-third of the sucrose present can be obtained crystalline, but for the production of alcohol this is immaterial. It is calculated that 130 galls. of alcohol (absolute) could be produced per acre of maize crop, and the period between the sowing of the maize and the gathering of the stems would be about 100 days. —J. H. L.

Maltose or lactose; Determination of —— in the presence of other reducing sugars. Legrand. Comptes rend., 1921, 172, 602—604.

Barfoed's solution (5 c.c. of 38% acetic acid added to 200 c.c. of a solution of 1 pt. of normal copper acetate in 15 pts. of water) is reduced by hexoses but not by disaccharides. Hexose sugars are estimated by boiling 5 c.c. of the sugar solution, containing not more than 0·1 g. of sugar, with 15 c.c. of Barfoed's solution for 3 mins. in a conical flask. The cuprous oxide is collected and estimated volumetrically as in Bertrand's method (J., 1907, 60). Total reducing sugars are then estimated by one of the usual methods with Fehling's solution. —W. G.

Rhamnose; Preparation of ——. C. F. Walton, jun. J. Amer. Chem. Soc., 1921, 43, 127—131.

The commercial product "Lemon Flavin" is rich in quercitrin and forms an excellent starting material for the preparation of rhamnose. The flavin is boiled for 30 mins. with 10 pts. of 0·5% sulphuric acid. The residue consisting of quercetin is filtered off and washed free from sugar, and the combined filtrates are neutralised with barium carbonate, decolorised, and concentrated under diminished pressure to a density corresponding to about 40% of solids. The liquid is then treated with 3 vols. of warm absolute alcohol, filtered, and the filtrate concentrated to a density corresponding to 70—80% of solids. On cooling the rhamnose crystallises out and may be purified by recrystallisation from 80% alcohol. A 20—25% yield is obtained. —W. G.

Colloids; Plant ——. IX. Various starches. M. Samec and H. Haerdtl. Koll. Chem. Beihefte, 1920, 12, 281—300.

All varieties of starch can be separated by electro-dialysis into a highly viscous and electro-conducting fraction (Meyer's β-amylose, Maquenne's amylopectin) and a non-viscous and non-conducting fraction (Maquenne's amylose). The amounts of these constituents vary from starch to starch, and dependent on the ratio of these amounts the water content of the starch granules varies as well as the viscosity and resistance to diastase of the solutions. All varieties of starch contain phosphorus; the following amounts per 100 g. of starch were found: potato, 0·112 g.; meadow saffron (*Colchicum autumnale*), 0·016 g.; maranta, 0·031 g.; tapioca, 0·012 g.; turmeric, 0·162 g.; horse-chestnut, 0·016 g.; wheat, 0·105 g.; maize, 0·034 g.; and rice, 0·039 g. The mean molecular weight varies with the different varieties thus: potato, 123,000; meadow saffron, 231,000; maranta, 260,000; tapioca, 208,000; turmeric, 158,000; horse-chestnut, 230,000; wheat, 170,000; *Oryza glutinosa*, 173,000; maize, 77,500; and rice, 110,000. (*Cf.* J.C.S. April.)—J. F. S.

Starch; Polarimetric determination of ——. H. Lührig. Pharm. Zentralh., 1921, 62, 141—144.

The effect of slight modifications of procedure in Ewers' method (J., 1908, 238) were investigated; the trustworthiness of the method is not affected by slight alteration in the strength of the acid used or in the treatment before and after the addition of the acid, but the time of heating prescribed (15 mins.) should not be exceeded. A method described by Mannich and Lenz (Z. Unters. Nahr. Genussm., 1920, 1), in which the starch is dissolved by heating with calcium chloride solution containing a small amount of acetic acid, and then polarised, also yields trustworthy results.—W. P. S.

Potash in molasses. Sherrill. *See* XXIII.

Patents.

Sugar-washing machine; Continuous ——. E. C. Carrick, Assr. to N. A. Lockwood. U.S.P. 1,367,946, 8.2.21. Appl., 19.1.20.

An endless movable filtering surface forms the peripheral wall of a series of chambers, which travel around a central axis. Means are provided for producing a vacuum within the chamber in the uppermost position with its filtering surface, on which the sugar is placed, at the top, so that the filtrate is drawn into the chamber, and for producing a pressure within the chamber in the lowest position with the filtering surface at the bottom, whereby the filtrate is expelled through the filtering surface. Means are also provided for removing the sugar from the filtering surface after the chambers have passed the vacuum zone and before they have entered the pressure zone.—J. H. L.

Karaya gum; Process of producing dry water-soluble products from ——. H. V. Dunham. E.P. 160,045, 20.1.20.

See U.S.P. 1,334,356—8 of 1920; J., 1920, 380 A.

XVIII.—FERMENTATION INDUSTRIES.

Malts; Iodometric determination of the diastatic power of ——. J. L. Baker and H. F. E. Hulton. Analyst, 1921, 46, 90—93.

The method described depends on the oxidation of maltose to maltobionic acid by iodine in alkaline

solution. Varying quantities (1, 2, or 3 c.c., etc.), of malt extract are allowed to act for 1 hr. at 21° C. on 100 c.c. of 2% soluble starch solution; action is then stopped by the addition of 10 c.c. of $N/10$ sodium hydroxide solution, and the mixture is diluted to 200 c.c. Fifty c.c. of this mixture is treated with 20 c.c. of $N/10$ iodine solution and 30 c.c. of $N/10$ sodium hydroxide solution; after 10 mins. 4 c.c. of $N/1$ sulphuric acid is added, and the excess of iodine is titrated with $N/20$ thiosulphate solution. Under these conditions the diastatic power$=16{\cdot}7Y/X$, where Y=c.c. of $N/10$ iodine solution used for the oxidation and X=c.c. of 5% malt extract taken for the conversion.—W. P. S.

Yeast; Nutritional requirements of ——. *I. Rôle of vitamins in the growth of yeast.* E. I. Fulmer, V. E. Nelson, and F. F. Sherwood. J. Amer. Chem. Soc., 1921, **43**, 186—191.

CULTURE experiments with extracts of alfalfa and wheat embryo show that water-soluble-B vitamin is not essential for the growth of yeast.—W. G.

Yeast; Nutritional requirements of ——. *II. Effect of the composition of the medium on the growth of yeast.* E. I. Fulmer, V. E. Nelson, and F. F. Sherwood. J. Amer. Chem. Soc., 1921, **43**, 191—199.

YEAST was grown satisfactorily for three months on a synthetic medium of inorganic salts and sucrose, devoid of calcium and magnesium. The optimum concentration of several ammonium salts examined was the same and corresponded to the concentration of ammonium chloride in which there was the minimum swelling of protein as measured by wheat gluten. The presence of certain colloids, such as dextrin, favoured the growth of the yeast.—W. G.

Fermentation; Water-soluble vitamin and substances accelerating ——. *I. Method for the determination and preparation of a substance from yeast and rice polishings which accelerates fermentation.* S. Fränkel and E. Schwarz. Biochem. Zeits., 1920, **112**, 203—235.

UTILISING the fact that extracts from yeast and rice polishings accelerate fermentation, the authors have worked out a method by means of which the accessory factor could be estimated. A fraction from yeast was prepared, having an activity 22 times greater than that of the alcoholic extract of the yeast, by successive precipitations with basic lead acetate, mercuric chloride, and phosphotungstic acid, this method giving better results than direct precipitation of the extract with phosphotungstic acid. (*Cf.* J.C.S., 1921, ii., 228.) —S. S. Z.

Enzymes; Chemistry of ——. T. Bokorny. Allg. Brauer- u. Hopfenzeit., 1920, 705—706, 713—714. Chem. Zentr., 1921, **92**, I., 372. (*Cf.* J., 1920, 202 A.)

NITROGEN is evolved on treatment of enzymes with nitrous acid, indicating the presence of amino-groups. The activity of emulsin is not destroyed by a 1% solution of nitrous acid. Whilst sulphurous acid is much more toxic than sulphuric acid to living organisms, possibly owing to the presence of free aldehyde groups in living protoplasm, there is little difference in the toxicity of the two acids towards enzymes; 1% solutions of both acids destroy the activity of emulsin, but 0·1% solutions have only a slightly injurious effect. By treatment of 2 g. of pressed beer yeast with 2 c.c. of 0·5% sulphuric acid, or 0·015 g. of formaldehyde, the yeast was killed without any considerable loss of zymase activity, whilst 3 c.c. of the acid or 0·25 g. of formaldehyde destroyed life and fermenting power: 0·005 g. of mercuric chloride killed 10 g. of yeast without destroying its fermenting power. Sucrose is fermented somewhat more rapidly than dextrose, and maltose about as rapidly as the latter. It is suggested that the dextrose liberated by hydrolysis of these disaccharides is more rapidly fermentable in the nascent state than in its usual form. —J. H. L.

Enzymes; Nature of oxidising and reducing ——. F. Battelli and L. Stern. Comptes rend. Soc. Biol., 1920, **83**, 1544—1545. Chem. Zentr., 1921, **92**, I., 332—333.

NUMEROUS experiments on the tissues of higher animals revealed a close parallelism between the oxidising power of the tissues in presence of molecular oxygen and their power of decolorising thionin by converting it into the leuco-base. The results confirm Wieland's hypothesis of the identity of oxidising and reducing enzymes. The action of oxidising enzymes may be regarded also as similar to that of hydrolytic enzymes, but in the latter case the two ions of water combine with the same molecule, whilst in the former the hydrogen ion combines with one molecule and the hydroxyl ion with another.—J. H. L.

Enzyme action; Relation of pressure and temperature to ——. *I. Influence of pressure on the velocity of peptic, tryptic, and diastatic hydrolysis.* S. Fränkel and G. Meldolesi. Biochem. Zeits., 1921, **115**, 85—95.

DURING the first two hours of peptic digestion there is more protein hydrolysed when the pressure is high than when the digestion is carried out under ordinary pressure. The acceleration of digestion is less at pressures above than at pressures below 5 atm. The acceleration in the velocity of hydrolysis during the first 2 hrs. effected by high pressure diminishes eventually. In the cases of trypsin the increase in the rate of digestion is more regular. Diastatic hydrolysis is accelerated by increased pressure during the first 2 hrs., after which time it becomes slower and then remains constant. —S. S. Z.

Fermentation of worts containing added sugars. J. O'Sullivan. J. Inst. Brew., 1921, **27**, 93—100.

FERMENTATIONS carried out with a large number of single-cell cultures prepared from three brewery yeasts indicated no appreciable differences in fermenting power. In experiments with a malt wort of sp. gr. 1·061, treated with sucrose, invert-sugar, dextrose, or maltose equivalent to 15% of the extract present, and fermented with 0·2 g. of pressed yeast for 10 days at the ordinary temperature, the whole of the added sugar, together with the fermentable matter of the wort, disappeared in all cases. In fermentations of solutions of the same concentration, but containing different proportions of fermentable sugars and the same quantity of nutrient matter, practically the whole of the fermentable sugars was fermented when the alcohol produced did not exceed 5%, but beyond this alcohol-content some of the sugar remained unfermented.—J. H. L.

Acetic and lactic acids; Fermentation process for the production of —— *from corn [maize] cobs.* E. B. Fred and W. H. Peterson. J. Ind. Eng. Chem., 1921, **13**, 211—213.

WHEN corn (maize) cobs are hydrolysed by heating with 0·5—2% sulphuric acid under a pressure of 15 lb. per sq. in., they yield 30—40% of their weight of xylose. The crude xylose syrup is fermented readily by *Lactobacillus pentoaceticus* with the formation of acetic and lactic acids; results of small scale experiments indicate that each ton of cobs would yield at least 300 lb. of acetic acid and 320 lb. of lactic acid.—W. P. S.

Alcohol; Rapid volumetric method for determining ——. A. Lachman. J. Ind. Eng. Chem., 1921, **13**, 230.

A definite weight (25 g.) of aniline is added to 50 c.c. of the alcohol-water mixture in which the alcohol is to be determined; if the aniline does not dissolve completely, some fixed volume, *e.g.*, 25 c.c., of strong alcohol of known strength is added. Water is then run in from a burette until a permanent turbidity is produced, and the temperature of the mixture is noted; if it is kept between 14° and 17° C., a correction is unnecessary. From the known volumes of the sample, of the added alcohol, and the added water, the percentage of alcohol in the sample can be calculated; the total volume of the solvent (alcohol plus water) is a nearly strictly linear function of the volume of the contained alcohol. Tables or graphs may be prepared (from actual determinations with known quantities of alcohol), and reference to these will give the percentage of alcohol directly from the volume of total solvent.—W. P. S.

Methyl alcohol; Determination of —— *in sulphite spirit.* R. Sieber. Papier-Fabr., 1921, **19**, 189—192.

Sulphite spirit is employed in Sweden for the production of potable spirits. The raw sulphite spirit contains, on the average, about 2·5% of methyl alcohol, and the brandy produced therefrom less than 0·5%. A slight modification of Denigès' method (J., 1910, 585) is recommended for the determination of methyl alcohol in the raw spirit. 1 c.c. of the ten-fold diluted sample (or more if the sample contains less than 1·5%) is mixed with 2·8 c.c. of water and 0·2 c.c. of sulphuric acid, and the cold mixture is treated with 1 c.c. of 5% permanganate solution and after 2 mins. decolorised and treated as described by Denigès. Comparative tests are made with 0·5 c.c. of a 1%, and 1 c.c. of a 0·1% solution of methyl alcohol in water or pure ethyl alcohol; if solutions in ethyl alcohol are employed 1 c.c. of permanganate solution should be used for each, but for aqueous solutions 0·5 c.c. is sufficient, water being added in all cases to bring the total volume to 5 c.c. The colorimetric comparison is made after the liquids have stood for 1 hr., or longer if possible, and Von Fellenberg's tables (J., 1915, 574) will be found useful.—J. H. L.

Glycerin; Process and apparatus for the continuous distillation of —— *from the residue obtained in the distillation of fermented liquids.* E. Barbet et Fils et Cie. E.P. 129,649, 9.7.19. Conv., 11.7.18.

After concentration to a sp. gr. of at least 1·25 in a multiple-effect apparatus, the fermentation residue is almost completely dehydrated in a suitable evaporator, and the hot syrup is then introduced into a column still, maintained under as complete a vacuum as possible, in which it is systematically exhausted by means of superheated steam, the glycerin distillate being carried over into a condenser, discharged therefrom under gravity, and subsequently concentrated. The column employed has plates with heating worms, and is provided with non-conducting or steam-jacketed walls; the steam bubbles through the liquid in the lower part of the column, and each plate is worked by superheated steam. The highly concentrated residue is discharged from the column under gravity, through a steam-jacketed pipe to prevent premature solidification.—J. H. L.

[Glycerol]; Process for manufacturing of propantriol —— *from sugar.* W. Connstein and K. Lüdecke. U.S.P. 1,368,023, 8.2.21. Appl., 13.8.19.

Solutions containing sugars are fermented by yeast, after addition of soluble salts of non-alkaline reaction in amounts more than sufficient for the nutrition of the yeast.—J. H. L.

XIXa.—FOODS.

Wheat; Changes taking place in the tempering of ——. E. L. Tague. J. Agric. Res., 1920, **20**, 271—275.

Before grinding wheat, it is the practice to add water to bring the total moisture present up to 15·5% and to allow to stand for 12—48 hrs., with the result that the bran is toughened and more readily separated and the flour obtained in higher yield and of better colour. The principal factors involved are amount of water added, time, and temperature. Three varieties of wheat were tempered with water in a closed bottle in a thermostat for a definite time, and were then ground to flour. Water extracts of the flours were prepared, and determinations were made of the hydrogen ion concentration, the total acidity, the soluble phosphorus, and the nitrogen titratable by the Sörensen formaldehyde method. Tempering at 5° C. caused little change in the flour compared with an untempered flour. At 20° C. chemical changes took place, each of the above determinations giving higher results than with the untempered flour; time also appeared to increase the action and the yield of flour was larger. At 40° C. the changes were more pronounced, but the milling properties of the wheat had deteriorated, especially after lengthening the time. Increasing the water to 18% produced a sticky flour. The general conclusion is drawn that the improved milling quality of tempered wheat is due chiefly to physical changes.—J. H. J.

Milk; Cryoscopy of ——. J. Hortvet. J. Ind. Eng. Chem., 1921, **13**, 198—208.

A detailed description is given of the procedure to be adopted and of apparatus recommended for use in determining the freezing point of milk. In the case of milk from individual cows, the freezing pt. varied from −0·534° to −0·562° C., whilst for mixed milk from a herd of cows it lay between −0·545° and −0·562° C.—W. P. S.

Colloids; Fixation of mineral salts by organic ——, *and the condition of the salts in some vegetables.* A. Scala. Ann. d'Ig., 1920, **30**, 251-273. Chem. Zentr., 1921, **92**, I., 333-334.

When certain neutral salts are brought into contact with colloids such as gelatin, agar, or muscle-flesh, acids are liberated to an extent dependent on the nature and the degree of dissociation of the salts and on the nature of the colloids. This effect is attributed to the ready hydrolysis of the anion of the adsorbed salt. On continued washing neutral and then basic wash-waters are obtained provided that the metal of the salt forms a soluble hydroxide (alkalis and alkaline earths); but in the case of heavy metals and aluminium the base remains fixed to the colloid. Beetroots, potatoes, etc., contain salts combined with colloids in this way, and their behaviour on continued washing is similar to that of the gelatin-salt complexes. These complexes are very stable at 0° C., but at 50°—70° C. they are

irreversibly modified and readily yield up their acids on washing. It is suggested that vitamins and accessory foodstuffs may owe their activity to inorganic salts combined with organic substances.
—J. H. L.

Rice; Products of putrefaction of polished ——. K. Yoshimura and K. Chenfon. Nippon Kwagaku Kwai Shi (J. Chem. Soc. Japan), 1921, 42, 22—37.

THE acids produced during the putrefaction of polished rice (2 kg. of rice with 4 l. water left to stand for 10 days at 30°—33° C.), were principally lactic acid (0·6%) and possibly acetic and butyric acids (0·67% as acetic acid). The following substances were isolated from 2 kg. of rice left to stand with 2 l. water for 19 and 33 days respectively: Iminazole-ethylamine (chloroplatinate, 0·8 and 0·2 g.), putrescine (hydrochloride, 0·7 and 2·0 g.), amylamine (trace and none), and ammonia (5·5 and 5·2 g.).—K. K.

Methyl anthranilate; Detection of —— *in fruit juices.* F. B. Power. J. Amer. Chem. Soc., 1921, 43, 377-381.

500 c.c. of the fruit juice is steam distilled, 200 c.c. of distillate being collected and extracted with 3 successive 10 c.c. portions of chloroform. The extract is filtered through a dry filter and the chloroform evaporated in a water bath in a current of air. The residue is at once dissolved in 2 c.c. of 10% sulphuric acid, cooled, and diazotised, the diazotised liquid being poured into 2 c.c. of alkaline β-naphthol solution. A yellowish-red precipitate is indicative of methyl anthranilate in the original juice, the test being sensitive to 0·0001 g. of the ester. Alternatively the diazotised liquid may be tested by the addition of dimethylaniline, but this process is not so sensitive.—W. G.

PATENTS.

Fatty emulsions [margarine]; Method for cooling or for allowing to crystallise concentrated ——. K. Erslev. E.P. 134,815, 25.9.19. Conv., 7.11.18.

A CLOSED vessel is connected at the top with an exhausting air pump and is provided with a central vertical shaft entering at the top of the vessel and terminating about midway of the height in a horizontal disc. A high vacuum is established in the vessel, and the emulsion is fed on to the upper face of the rotating disc through an inlet pipe, whereby it is sprayed into the exhausted space and thereby cooled. The cooled emulsion is removed from the bottom of the vessel by a worm conveyor. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Acts, 1907 and 1919, to E.P. 3555 of 1890.)—A. DE W.

Food products; Apparatus for dehydrating ——. G. A. Sykes, Assee. of F. L. Nichols. E.P. 146,917, 6.7.20. Conv., 4.2.19.

A METAL casing, open at the bottom, is provided with sloping baffle plates arranged so as to form a central flue closed at the top and tapering upwards, and two side flues closed at the bottom and tapering downwards. Trays with wire gauze bottoms for containing the material slide into slots attached to the upper edge of one baffle plate and the lower edge of the plate above. Hot air, *e.g.*, from a stove, passes up the central flue, through the trays, and out through the side flues.—L. A. C.

Food; Manufacture of articles of —— *[with the aid of sour whey solids].* C. S. Townsend. E.P. 158,684, 10.11, 6.12, and 13.12.19.

THE dried solids of sour whey from the manufacture of cheese, are employed as an ingredient of bread, pastry, confectionery, baking powders, and the like.—J. H. L.

Flour; Treatment of ——. H. Greville. E.P. 158,917, 27.6.19.

SODIUM or calcium per-metaphosphate and/or per-pyrophosphate, or the corresponding acids in the dry state, prepared by evaporating *in vacuo* a mixture of hydrogen peroxide and a metaphosphate or pyrophosphate, or by electrolysis of cooled solutions of a metaphosphate or pyrophosphate, are added to flour. (*Cf.* E.P. 124,298; J., 1919, 385 A.)
—L. A. C.

Flour and similar meals; Method for improving ——. Naaml. Vennoots. Industriele Maatschappij voorh. Noury & van der Lande. G.P. 330,694, 15.8.17. Addn. to 312,528 (J., 1919, 842 A).

BY submitting flour repeatedly to rapid cooling and heating, the weight and volume of the bread obtainable from it are increased.—D. F. T.

Cheese and process for sterilising same. G. H. Garstin, Assr. to Phenix Cheese Co. U.S.P. 1,368,624, 15.2.21. Appl., 28.10.20.

COMMINUTED cheese is mixed with about 5% of sodium phosphate, and sterilised. Sterilised cheese containing tertiary sodium phosphate is claimed.
—J. H. L.

Eggs; Preservation of ——. E. Utescher. G.P. 328,423, 9.12.14.

THE eggs are preserved in water containing, in suspension, magnesium hydroxide, with or without the addition of calcium hydroxide.—L. A. C.

Milk; Process and apparatus for the drying of —— *in a porous form.* L. Jäger. G.P. 329,215, 25.11.19.

THE milk is boiled and the froth produced is conducted into a drying apparatus.—J. H. L.

Lupins and other leguminous seeds; Removal of bitter substances from —— *by means of alcoholic solvents.* C. F. Hildebrandt and B. Rewald. G.P. 329,216, 29.1.18.

THE material is extracted in the cold with aqueous methyl alcohol, or mixtures of methyl alcohol with fat solvents. Fats and bitter substances may thus be extracted from the whole seeds, after treatment with water or steam.—J. H. L.

Foodstuffs; Extraction of —— *with water or aqueous solutions.* L. Engelhardt. G.P. 329,505, 17.12.18.

THE bitter constituents of lupin seeds, acorns, soya beans, or the like, are removed by alternate extraction with water or an aqueous solution and electrolytic treatment of the not too finely divided material.—L. A. C.

Straw fodder or the like; Treatment of gases from apparatus for drying light, glutinous, absorbent material, such as ——. L. Roselius. G.P. 330,186, 3.1.17.

THE hot gases from the dryer are diverted sideways in the exit shaft and sprayed with a jet of water at right angles to their path. The impact of the water and absorption of the same by the fine material in suspension cause the material to fall into a receiver below.—L. A. C.

Sterilising liquids; Process of removing germs, ferments, and toxins from and ——. H. Bechhold. G.P. 329,189, 14.3.19. Addn. to 325,505 (J., 1920, 831 A).

The porous material, *e.g.*, kieselguhr, is coated with a metal, *e.g.*, copper or silver, and with an insoluble compound of another metal, *e.g.*, silver or copper oxide.—L. A. C.

Antiseptic; Manufacture of a colloidal ——. Chinoin-Fabr. chem.-pharm. Produkte, A.-G. (v. Kereszty und Wolf). G.P. 329,733, 27.9.18. Conv., 16.5.18.

Sufficient *Magnesia usta*, or a colloidal metallic hydroxide or inorganic acid, *e.g.*, silicic acid, is added to a solution of an alkali, alkaline-earth, or magnesium hypochlorite, to give a mixture which sets within a day to a pasty consistency. The product is as powerful an antiseptic as mercuric chloride for disinfecting the hands and body, but has not its poisonous properties.—L. A. C.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Atropine sulphate from Datura stramonium. H. W. Rhodehamel and E. H. Stuart. J. Ind. Eng. Chem., 1921, **13**, 218—220.

The following method was used for extracting the alkaloids:—10 tons of the ground plant was percolated with water containing 0·2% of sulphuric acid and 0·5% of formaldehyde; the percolate, in 1500-gal. portions, was then treated with fullers' earth, allowed to settle, the sludge collected, and dried at 50° C. The adsorbed alkaloids were separated from the dried sludge by extraction with alcohol, using lime to obtain the proper alkalinity; the extracts were acidified with acetic acid and concentrated first to 12% and then under reduced pressure to 2% of the original volume. This treatment was sufficient to convert all the hyoscyamine present into its isomeride, atropine. The solution was then rendered ammoniacal, the atropine extracted with ether, the ethereal solution evaporated, and the residual alkaloid dried at 35° C. The dry alkaloid was dissolved in alcohol, the solution neutralised with sulphuric acid, evaporated to a syrup, and the latter while hot treated with acetone until precipitation almost commenced; on cooling, atropine sulphate was obtained in crystalline form.
—W. P. S.

Charcoal; Comparative experiments on the adsorptive capacity [for alkaloids, toxins, etc.] of various kinds of ——. F. Horst. Biochem. Zeits., 1921, **113**, 99—110.

The results obtained by the methods of Wiechowski and Joachimoglu (Biochem. Zeits., 1916, **77**, 1) for the determination of the adsorptive capacity of charcoal, using solutions of Methylene Blue and of iodine respectively, indicate satisfactorily the adsorptive power of the charcoal for chemically defined poisons (strychnine, neurine), but not for toxins such as diphtheria, tetanus, and ricin toxins.
—S. S. Z.

Shepherd's purse [Capsellae bursae, Pastoris]; Active constituents of ——. H. Boruttau and H. Cappenberg. Arch. Pharm., 1921, **259**, 33—52.

Physiological investigation showed the extracts of the drug to contain a substance which causes very marked depression of the blood pressure and also a product which causes rise in the blood pressure and which is carried down by the precipitate when mercuric chloride is added to the extract. The latter substance is probably tyramine, but it could not be identified with certainty by reason of the small amount of substance available. It is very improbable that histamine is present. Chemical evidence of the presence of an alkaloid could not be obtained with the available material. The isolation of choline and acetylcholine from the liquid extracts is described in detail; the choline bases can also be obtained directly from such preparations by precipitation with alcoholic platinic chloride solution without previous use of lead, mercury, or barium salts, and the following method of evaluating the extract is based on this observation. The extract (1:1, 5 c.c.) is mixed with alcohol (12 c.c.) and treated with alcoholic platinic chloride solution (1%, 20—25 c.c.); the precipitate is filtered off after one or two days, dried, and subsequently extracted on the filter with hot water, the impurities remaining on the filter. The filtrate is evaporated in a tared dish. If necessary, the concentrated filtrate is again filtered or, should it become turbid, is precipitated with 70% alcohol. A good sample of the drug should yield at least 0·2 g. of platinum chlorine compounds; the purity of the isolated platinichlorides is controlled by observation of the melting point or by estimation of platinum or nitrogen.—H. W.

Lobinol, a dermatitant from Rhus diversiloba (Poison oak). J. B. McNair. J. Amer. Chem. Soc., 1921, **43**, 159—164.

Lobinol, a poisonous, amber-red, oily liquid, has been isolated from the bark of *Rhus diversiloba*. From its chemical behaviour it is probably an unsaturated *o*-dihydric phenol. It is easily darkened, dried, and hardened by means of manganese, barium, or magnesium peroxides, litharge, manganese hydroxide, and potassium bichromate. It hardens at a temperature above 96° C. in the absence of its enzyme or any oxidising agent.
—W. G.

Siam benzoin. II. Siaresinolic acid. F. Reinitzer. Arch. Pharm., 1921, **259**, 1—6.

d-Siaresinolic acid (*cf.* Zinke and Lieb, J., 1918, 520 A) is best prepared by treating the crude benzoin with aqueous sodium hydroxide solution (4—5%) when sodium *d*-siaresinolate remains as a very sparingly soluble precipitate which can be crystallised from alcohol. The free acid has $[\alpha]_D^{15.6}$ $=+37·793$ in ethyl alcoholic solution (96%), m.p.

260° C. (Zinke and Lieb, m.p. 274°—275° C.). It does not contain a methoxy group and plays no part in the gradual discoloration suffered by the resin when preserved. Potassium *d*-siaresinolate crystallises in needles which dissolve freely in water and alcohol. The name, *l*-prabangic acid, is proposed for the substance, $C_{47}H_{46}O_4$, isolated by Zinke and Lieb by the oxidation of *d*-siaresinolic acid by chromic acid in acetic acid solution.—H. W.

Siam benzoin. III. Properties and constitution of lubanyl benzoate. F. Reinitzer. Arch. Pharm., 1921, 259, 60—69.

LUBANYL benzoate (J., 1915, 681) crystallises in plates, m.p. 72·8° C., and contains one methoxy group. It is readily oxidised when exposed to warm air and then exhibits a series of colour changes which are precisely analogous to those shown by the crude resin. It readily loses benzoic acid when heated at 120°—140° C., and on further rise of temperature emits the odour of oil of carnations and subsequently of guaiacol. It is optically inactive. The benzoate is very readily hydrolysed either in acid or alkaline solution, but the isolation of lubanol in the pure condition has been impossible up to the present on account of the great susceptibility of the substance, particularly in alkaline solution, to further change. Lubanol is probably identical with or very closely related to coniferyl alcohol.—H. W.

Oxynitrilase; Properties of ——. V. K. Krieble and W. A. Wieland. J. Amer. Chem. Soc., 1921, 43, 164—175.

THE formation of *d*-mandelonitrile by the action of oxynitrilase from peach leaves on benzaldehyde and hydrogen cyanide has a different temperature coefficient from the formation of the inactive nitrile by the spontaneous interaction of the components. At 0° C. the enzyme action is more efficient, but at 35° C. the spontaneous action is the more marked. The ratio of these two actions is, however, very considerably influenced by the hydrogen-ion concentration. (*Cf.* J.C.S., 1921, i., 283.) —W. G.

Anæsthesin; Derivatives of ——. H. Thoms and K. Ritsert. Ber. deuts. Pharm. Ges., 1921, 31, 65—75.

A NUMBER of derivatives of anæsthesin (ethyl *p*-aminobenzoate) were prepared in which the hydrogen atom of the amino-group was replaced by various positive and negative groups, with the object of determining the effect of such substitution on the anæsthetic properties of the base. In general the physiological action was much reduced by the substitution of the amino hydrogen atoms, and entirely disappeared with the introduction of negative groups. Only in the case of *p*-carbethoxyphenylhydrazine, where an amino hydrogen atom of anæsthesin had been replaced by an amino group, was the anæsthetic action at all comparable with that of anæsthesin itself. Among the substances described are N-allyl-N′-*p*-carbethoxyphenylthiourea, *p*-carbethoxyphenylhydrazine, *p*-carbethoxyphenylmethylpyrazolone, *p*-carbethoxyphenylurethane, and *p*-nitrobenzoyl-*p*-aminobenzoic acid ethyl ester. (*Cf.* J.C.S., May.)—G. F. M.

Anæsthesin and some of its derivatives; Anæsthetic action of ——. J. Morgenroth. Ber. deuts. Pharm. Ges., 1921, 31, 76.

COMPARATIVE tests of the anæsthetic action of anæsthesin and certain of its derivatives (*cf. supra*) were made on the cornea of the rabbit. Treatment for 3 mins. with anæsthesin itself rapidly produced anæsthesia lasting 32 mins. *p*-Carbethoxyphenylhydrazine gave almost similar results, whilst N-allyl-N-*p*-carbethoxyphenylurea had a scarcely perceptible action. As regards soluble compounds, carbethoxyphenylhydrazine hydrochoride in 2% solution produced after 3 mins. anæsthesia lasting 9 mins. The insoluble substances thus act more powerfully than their soluble salts.—G. F. M.

Benzyl esters possessing an antispasmodic action; New ——. H. A. Shonle and P. Q. Row. J. Amer. Chem. Soc., 1921, 43, 361—365.

THE benzyl esters of the higher fatty acids may readily be prepared either by the action of benzyl alcohol on the acid chloride or by the action of benzyl chloride on the alkali salt of the fatty acid dissolved in an excess of the hot fatty acid. These esters are tasteless and odourless and have an antispasmodic action. They are more readily hydrolysed by lipase than are the benzyl esters of aromatic acids. Therapeutically the esters of individual acids have nothing to recommend their use over that of the esters of mixtures of fatty acids derived from naturally occurring sources. (*Cf.* J.C.S., May.)—W. G.

Benzyl succinate; its composition, manufacture, properties, and probable therapeutic uses. M. Bye. J. Ind. Eng. Chem., 1921, 13, 217—218.

BENZYL succinate is obtained by heating succinic acid with benzyl alcohol; it forms snow-white crystals and is practically non-toxic. The benzyl group constitutes 61·08% of the molecule, and the substance may be used medicinally with advantage in any conditions where the use of benzyl benzoate is indicated.—W. P. S.

Arsphenamine [salvarsan]; Indirect reduction of 3-amino-4-hydroxyphenylarsonic acid to ——. W. G. Christiansen. J. Amer. Chem. Soc., 1921, 43, 370—375.

3-AMINO-4-HYDROXYPHENYLARSONIC acid is reduced by means of hydriodic acid and sulphur dioxide in hydrochloric acid solution to 3-amino-4-hydroxyphenylarsenious oxide hydrochloride. The excess of sulphur dioxide is removed by aeration and the liquid further reduced by hypophosphorous acid (J., 1921, 97 A) and poured into hydrochloric acid (1:1), the arsphenamine being precipitated as its dihydrochloride in a form readily soluble in water and of low toxicity. If the excess sulphur dioxide is removed by boiling the liquid, the product of the second reduction is arsphenamine polyarsenide. When 3-amino-4-hydroxyphenylarsenious oxide is boiled in hydrochloric acid, *o*-aminophenol is the final product, 3.3′-diamino-4.4′-dihydroxydiphenylarsenious oxide being formed as an intermediate product.—W. G.

Phenylacetic-p-arsonic acid. G. R. Robertson and J. Stieglitz. J. Amer. Chem. Soc., 1921, 43, 179—181.

PHENYLACETIC-*p*-ARSONIC acid, $CO_2H.CH_2.C_6H_4.AsO_3H_2$, prepared from *p*-aminophenylacetic acid by Bart's reaction (*cf.* J., 1911, 1087), forms white, glistening leaflets, slightly soluble in cold water, very soluble in hot water and in alcohol. When introduced into a heated melting-point bath it melts quietly at about 195° C., but if heated gradually it undergoes change and does not melt below 270° C. (*Cf.* J.C.S., 1921, i., 284.)—W. G.

Toluenesulphonamides; Separation of o- and p- ——. W. Herzog and I. Kreidl. Chem.-Zeit., 1921, 45, 231.

A METHOD described by O. Beyer for the separation of *o*- and *p*-toluenesulphonamides by heating the mixture with 10% sulphuric acid, in which it is stated that the *p*-sulphonamide is insoluble, is useless when a large proportion of the *p*-sulphonamide is present, since the whole mixture dissolves. In the case, however, of a mixture containing not

more than 2% of the p-sulphonamide, it is possible to separate the latter by dissolving the mixture in hot 10% sulphuric acid; on cooling, the p-sulphonamide crystallises out, whilst the greater part of the o-sulphonamide remains in solution.—W. P. S.

Halogenation. XX. Replacement of sulphonic acid groups by halogens. R. L. Datta and J. C. Bhoumik. J. Amer. Chem. Soc., 1921, **43**, 303—315.

The replacement of sulphonic groups in aromatic compounds by chlorine or bromine (J., 1920, 172 A) takes place generally and may occur with iodine under special conditions. Instead of using free bromine it is better to use a mixture of alkali bromide and bromate, as the bromine is liberated very gradually with simultaneous substitution and the chances of charring and secondary reactions are eliminated altogether. Similarly a mixture of iodide and iodate will in some cases effect a replacement which free iodine itself fails to do. A mixture of chloride and chlorate, however, gives no better results than free chlorine itself. Groups already present in the nucleus exert a great influence on the replacement of sulphonic acid groups by halogens, and certain general rules have been observed. With compounds having one or more hydroxyl groups present in the nucleus the replacement takes place readily at the ordinary temperature, although if there are two hydroxyl groups ortho to one another oxidation often occurs. The presence of an amino group similarly facilitates the replacement, but nitro groups, on the other hand, have a retarding effect. In the case of hydroxycarboxylic acids, the sulphonic group is replaced by halogens, but at the same time the carboxyl group is detached. The presence of halogen atoms in the compound makes the replacement difficult. The presence of alkyl groups also renders the replacement difficult, but the effect is variable. The replacement of the sulphonic group by halogens takes place more easily in the case of a monosulphonic acid than in the case of a di- or a trisulphonic acid. (*Cf.* J.C.S., May.)—W. G.

Epichlorohydrin; Action of —— on disodium phosphate in aqueous solution and the stability of a monoglyceromonophosphoric di-ester. O. Bailly. Comptes rend., 1921, **172**, 689—691.

When epichlorhydrin and disodium phosphate are mixed together in aqueous solution in equimolecular proportions and the solution is allowed to stand, the amount of phosphorus precipitable by magnesia mixture steadily diminishes and there is a progressive formation of sodium chloride. Under these conditions a mixture of a mixed glycido-chloroglycerophosphoric ester and a monoglyceromonophosphoric di-ester, $NaO.PO(O.CH_2)_2.CH.OH$, probably results, but if the solution is boiled for 2 hrs., the di-ester is almost the sole product. It is remarkable that this di-ester should be stable in boiling solution.—W. G.

Cyanic acid and urea; Synthesis of —— by oxidation in ammoniacal solution of alcohols, phenols, and aldehydes. R. Fosse and G. Laude. Comptes rend., 1921, **172**, 684—686.

Methyl, ethyl, and butyl alcohols, phenol, o-cresol, α- and β-naphthols, catechol, resorcinol, acetaldehyde, propaldehyde, and butaldehyde, all yielded cyanic acid on oxidation in ammoniacal solution with potassium permanganate alone or in the presence of ammonium sulphate, copper carbonate, or copper powder. The cyanic acid was converted into urea by treatment with ammonium chloride. —W. G.

Triacetin; Successive stages of hydrolysis of ——. E. Yamasaki. Sci. Rep. Tohoku Imp. Univ., 1920, **9**, 451—471.

If the rate of hydrolysis of each of the three ester radicles in triacetin is equal and the reaction is in each case unimolecular, it follows that, if k_1 is the constant for the reaction $C_3H_5(O.C_2H_3O)_3 \rightarrow C_3H_5.(OH)(O.C_2H_3O)_2 + CH_3CO_2H$, k_2 for the reaction $C_3H_5(O.C_2H_3O)_2(OH) \rightarrow C_3H_5(OH)_2(O.C_2H_3O) + CH_3.CO_2H$, and k_3 for the reaction $C_3H_5(OH)_2(O.C_2H_3O) \rightarrow C_3H_5(OH)_3 + CH_3CO_2H$, the relation between these contants is such that $k_1/3 = k_2/2 = k_3 = k$. This conclusion was verified experimentally, the velocity constants being determined graphically from the hydrolysis curves of triacetin, diacetin, and monoacetin. The experiments were carried out at 35° C. and the curves obtained by plotting the concentration of acetic acid against time. Knowing the value of k, the concentrations of mono-, di-, and triacetin at any time can be calculated. The velocity of hydrolysis is approximately doubled for each 10° C. rise in temperature.—E. H. R.

Amines of secondary alcohols; Preparation of ——. A. Mailhe. Comptes rend., 1921, **172**, 692—694.

The hydrogenation of ketazines of symmetrical ketones (*cf.* Comptes rend., 1920, **170**, 1265) has been successfully extended to the hydrogenation of the ketazines of unsymmetrical ketones. The product is in all cases a mixture of primary and secondary amines of secondary alcohols. Numerous examples are given. (*Cf.* J.C.S., May.)—W. G.

Tetrachloroethane and trichloroethylene; Preparation of —— from acetylene and chlorine. S. Igi. Kōgyō Kwagaku Zasshi (J. Chem. Ind. Japan), 1920, **23**, 1217—1237.

Tetrachloroethane is prepared by passing alternately acetylene at 60°—80° C. and chlorine at 80°—100° C. into antimony pentachloride. 100 g. of antimony chloride suffices for the preparation of 150—180 g. of tetrachloroethane; the recovery of the catalyst is difficult and unprofitable. The rate of absorption of the acetylene and chlorine by the pentachloride is at first high, but diminishes rapidly; the effect of impurities is not large. Trichloroethylene is prepared by heating a mixture of tetrachloroethane and milk of lime, a yield of 84% of the theoretical value being obtained. Some excess of lime is advantageous, *e.g.*, 60 g. of slaked lime and 50 g. of water for 100 g. of tetrachloroethane. —K. K.

Formaldehyde; Adsorption of —— by animal charcoal. W. Moeller. Kolloid-Zeits., 1921, **28**, 127—132.

Formaldehyde is strongly adsorbed by animal charcoal both from acid and neutral solutions. In acid solution the adsorption depends on the volume of solution, but this is not the case in neutral solutions. Equilibrium is set up immediately in neutral solutions, but in acid solutions is not complete even after eight days.—J. F. S.

Oxalic acid; Formation of —— from sulphite-cellulose waste liquors and from lignin. E. Heuser, H. Roesch, and L. Gunkel. Cellulosechem., 1921, **2**, 13—19.

Lignin free from carbohydrates produced no oxalic acid on fusion with potassium hydroxide at temperatures up to 270° C.; sulphite waste liquors under similar conditions often yield oxalic acid owing to the presence of cellulose and other carbohydrates in them. Oxidation of lignin with fuming nitric acid gave yields of oxalic acid up to 25% (20% actually isolated); addition of small quantities of ferrous or mercurous sulphate or ammonium vanadate reduced the yield, and the use of mixtures

of nitric and sulphuric acids produced no oxalic acid at all, doubtless owing to the destructive action of the sulphuric acid. On heating 3 g. of lignin with 60 g. of dilute nitric acid (25%) for 4 hrs. at 80°—90° C., a clear solution was obtained from which 0·13 g. of oxalic acid was isolated; the yield was increased to over 17% by addition of 0·01 g. of ferrous or mercurous sulphate, but larger amounts of these catalysts acted less favourably.—J. H. L.

Mustard oil [allyl isothiocyanate]; Cause and composition of the insoluble deposits in ——. H. Kunz-Krause. Arch. Pharm., 1921, **259**, 16—33.

NATURAL and synthetic mustard oil becomes discoloured when preserved and slowly deposits a dark orange to lemon yellow precipitate. The latter contains colourless quadratic prisms and small quantities of hexagonal plates, cubes, and slender prismatic needles. A portion of the deposit is soluble in water and consists principally of allylamine sulphate possibly admixed with traces of ammonium sulphate. The chief constituent of the portion insoluble in water is pseudothiocyanogen, $C_3HN_3S_3$, whilst isoperthiocyanic acid, $C_2H_2S_3N_2$, and allyl-substituted ureas are most probably also present. The formation of the substances is traced to the conjoint action of air, moisture, and light on the oil, which is best preserved in small, well-filled, dry bottles of green glass. (*Cf.* J.C.S., May.) —H. W.

Wormseed oil; Reaction of American ——. A. Langer. Pharm. Zeit., 1921, **66**, 191.

OIL of American wormseed (*Chenopodium ambrosioides*) yields a red-yellow resin when heated at about 175° C. with phenolphthalein in the presence of toluene; 10 g. of the oil requires about 4 g. of phenolphthalein. After the product has been steam distilled to remove terpenes and toluene, any excess of phenolphthalein may be removed by dissolving the resin in warm toluene. The resin is soluble in chloroform, alcohol, ether, and alkali solutions and is precipitated by acids from the latter solutions as a yellow powder which melts below 100° C. to give the red resin.—W. P. S.

Thymol and carvacrol; Urethanes of ——. D. C. L. Sherk. Amer. J. Pharm., 1921, **93**, 115—125.

THE urethanes mentioned below were prepared by simply heating a mixture of thymol or carvacrol and the phenolic isocyanate together with a paraffin hydrocarbon of b.p. 170°—200° C. for about 1 hr.; the urethanes crystallised from the mixture on cooling. Thymol phenyl urethane, m.p. 106·5°—107° C., yield, 71%; carvacrol phenyl urethane, m.p. 138° C., yield 86%; hydrothymoquinone phenyl diurethane, m.p. 229°—230° C., yield 84%; thymol α-naphthyl urethane, m.p. 156°—157° C., yield 43%; carvacrol α-naphthyl urethane, m.p. 117°—119° C., yield 36%. Dibenzoylhydrothymoquinone, m.p. 141°—142° C., yield 75%, was obtained by dissolving hydrothymoquinone in a slight excess of 15% sodium hydroxide solution and then adding benzoyl chloride.—W. P. S.

Borneol and its alkyl derivatives; Determination of —— by acetylation. F. Martin. J. Pharm. Chim., 1921, **23**, 168—171.

BORNEOL is acetylated completely when heated at 145°—150° C. for 3 hrs. with three times its weight of acetic anhydride and a small quantity of fused sodium acetate. After the acetylated product has been washed with water and 5% sodium carbonate solution, and dried over anhydrous sodium sulphate, the quantity of borneol present is found by determining the saponif. value of the acetylated product; in the calculation allowance is made for the increase of molecular weight (by 42 units) due to the acetylation.—W. P. S.

Oligodynamic action of the heavy metals and of the salts of the heavy metals; So-called ——. W. Falta and M. Richter-Quittner. Biochem. Zeits., 1921, **115**, 39—41.

THE oligodynamic action of various metals was tested in the following way:—a test-tube was filled with water containing the respective metals and was allowed to stand for eight days. The metal and the water were then removed, the tube rinsed out with distilled water, and its oligodynamic action tested on different solutions. It was found that guaiacol, benzidine, resorcinol, and homogentisinic acid were oxidised when kept in test-tubes prepared in the above way. Potassium permanganate was decolorised with the formation of manganese dioxide. Methylene Blue, Indigo Blue, and sodium indigosulphonate were decolorised and the leuco-base of Malachite Green was oxidised. Protein solutions were coagulated through the oligodynamic action of the metals. This oligodynamic action was shown by the following metals which are arranged in the order of their activity:—copper, mercury, silver, lead, tin, aluminium, iron, magnesium, and platinum.—S. S. Z.

PATENTS.

Tea plants; Treatment of the waste cut from growing —— and the obtainment of caffeine therefrom. R. L. Datta. E.P. 159,097, 1.3.20.

THE leaves and stems cut from growing tea plants are dried, ground, and extracted with water. The aqueous extract is treated with lime, and the calcium tannate precipitated is separated by filtration. Crude caffeine crystallises from the solution after concentration, and is purified by solution in chloroform, filtration, evaporation of the solvent, and recrystallisation of the product from hot water. —L. A. C.

Copper-tannin-albumin compound; Preparation of a ——. P. Beiersdorf und Co. G.P. 325,957, 24.6.19.

A COMPOUND in which the therapeutic properties of tannin are improved by the presence of copper, is prepared by heating a mixture of an alkaline casein solution, a copper salt, and a tannin solution. The product, which contains 5·42% H, 48·85% C, 7·45% N, and 4·95% Cu, is an odourless, brown powder with a faint metallic taste. —L. A. C.

Salts corresponding to the salts contained in the human blood; Manufacture of a mixture of dry —— soluble in water to a clear solution. Sächsisches Serumwerk und Inst. für Bakteriotherapie, G.m.b.H. G.P. 329,309, 7.10.19.

A SALT mixture from which no calcium salts separate on solution in water is prepared by adding powdered calcium chloride, of which each particle is coated with a layer of a colloid, such as gelatin, which swells on addition of water, to a mixture of blood serum salts.—L. A. C.

Mercury-casein ointment or emulsion; Manufacture of a ——. C. Biedermann. G.P. 329,429, 29.5.18.

MERCURY is worked up to a paste with neutral, freshly precipitated casein and water to yield a non-irritant ointment.—L. A. C.

Salves and emulsions; Bases for —— capable of holding a large proportion of water. I. Lifschütz. G.P. 329,605, 11.5.19. Addn. to 324,012 (J., 1920, 833 A).

ANIMAL fats prepared from blood or brains containing a large proportion of metacholesterol are employed instead of pure metacholesterol, as described in the chief patent.—L. A. C.

Salves; Manufacture of adsorptive ——. Elektro-Osmose A.-G. (Graf Schwerin Ges.). G.P. 329,672, 24.2.16.

COLLOIDAL silicic acid containing, *e.g.*, 12% of silicic acid, is mixed with 5% of glycerin, 10% of paraffin or vaseline, 25% of Peru balsam, or with other similar materials.—L. A. C.

Furfuracrolein; Preparation of ——. W. König and K. Hey. G.P. 330,358, 12.11.19.

FURFURACROLEIN, m.p. 54° C., which is suitable for use as a flavouring essence or perfume, is prepared by the gradual addition of acetaldehyde to an alkaline solution of furfural at a low temperature, *e.g.*, 0° C.—L. A. C.

Methyl bromide; Production of ——. G. Schroeter. G.P. 330,642, 25.11.17.

A MIXTURE of methane, or gases containing the same, and bromine is led, above 200° C., over a catalyst such as iron, copper, nickel, or cobalt, or other metals having more than one valency, or mixtures of the same. If methane is bubbled through a depth of 5—6 cm. of liquid bromine and led, at a velocity of 2 litres per min., through tubes of 20 mm. diam. containing iron powder and heated for a length of 250 mm. to 250°—300° C., the product contains 50% of unchanged methane; if the proportion of bromine in the gas is increased, methylene dibromide and tribromomethane are formed in addition to methyl bromide.—L. A. C.

Cinchona alkaloids; Preparation of compounds containing selenium from hydrogenated ——. Ver. Chininfabr. Zimmer und Co., G.m.b.H. G.P. 331,145, 30.11.17.

COMPOUNDS of therapeutic value are prepared by the action of selenium dioxide on hydrogenated cinchona alkaloids, or their derivatives, in the presence of concentrated sulphuric acid. The product is diluted with water, and boiled. Selenohydroquinine, prepared from hydroquinine sulphate or hydroquinine sulphuric acid ester, forms bright yellow needles from alcohol, m.p. above 235° C.; selenoethylhydrocupreine forms yellow needles, m.p. 233°—234° C., and selenohydrocupreine forms bright orange needles, m.p. above 235° C., soluble in sodium hydroxide solution.
—L. A. C.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Reflection and density meter for photographic papers. K. Kieser. Phot. Korr., 1920, 17, 287—289.

THE paper to be tested is illuminated at 45° and viewed through a polarisation photometer, at 45° for reflection measurements and at 90° for density measurements.—B. V. S.

Eder-Hecht grey-wedge photometer. J. M. Eder. Phot. Korr., 1920, 57, 304—307.

SEVERAL minor improvements have been made in the instrument (J., 1920, 803 A). Particulars are given, with curves, of the spectral absorptions of the four colour-filters, red, yellow, light green, and blue, which are combined with the grey wedge.
—B. V. S.

Safranine-quinol, a cheap and rapid developer. Lüppo-Cramer. Der Photograph, 1921, 65—66.

THE addition of Phenosafranine to an ordinary caustic alkali quinol developer, up to a strength of 1:20,000, produces a developer resembling metol-quinol and nearly, though not quite, as rapid in action. A further increase in the proportion of Phenosafranine has practically no effect on the speed. Where the most rapid development is not essential this developer is recommended on account of its cheapness, while it has the additional advantage of allowing development in bright light.
—B. V. S.

XXII.—EXPLOSIVES; MATCHES.

Nitrous acid; Determination of —— in mixed and waste acids. H. Toussaint. Z. angew. Chem., 1921, 34, 102.

FOR the estimation a Woulff bottle with three necks is used, through the outer ones of which pass a funnel, and an inlet tube for carbon dioxide, respectively. 700 c.c. of air-free, distilled water is placed in the bottle, and the air is displaced by carbon dioxide. A suitable amount of the acid to be tested is run in through the middle neck from a burette, after which a glass tube, 10 cm. long, is fixed in the neck by a collar of rubber tubing, so that its lower end is flush with the top of the bottle: the carbon dioxide tube is next pushed down to the bottom of the bottle. Potassium iodide solution is run in through the funnel and the solution titrated with $N/2$ or $N/10$ thiosulphate, introduced through the middle neck, together with starch solution if desired, the titration being conducted in a slow current of carbon dioxide. If the acids contain a considerable amount of ferric oxide, this must first be removed by treatment with sodium hydroxide, free from nitrate, after which the filtrate is acidified with pure sulphuric acid.—W. J. W.

PATENTS.

Smokeless powders; Manufacture of ——. Westfälisch - Anhaltische - Sprengstoff - A.-G. G.P. 329,775, 15.7.13.

ADDITION of di-substituted urethanes, especially methylphenylurethane, to mixtures of nitroglycerin and nitrocellulose containing not more than 30% of nitroglycerin, enables the material to be pressed at temperatures below 82° C. Volatilisation of the nitroglycerin is thereby reduced, and a stable explosive is produced.—W. J. W.

Matches; Manufacture of damp-proof ——. R. Dubrisay. E P. 145,798, 2.7.20. Conv., 3.7.19.

SEE U.S.P. 1,363,095 of 1920; J., 1921, 130 A.

XXIII.—ANALYSIS.

Analysis; Use of spot reactions in qualitative ——. F. Feigl and R. Stern. Z. anal. Chem., 1921, 60, 1—43.

SPOT reactions, usually made on filter paper, are shown to be applicable to the identification and detection of a large number of substances when these occur either alone or in mixtures. The reactions of aluminium, uranium, and chromium with alizarin dyes (formation of lakes) are very sensitive, as is also the reaction of manganese with benzidine.
—W. P. S.

Analysis by means of reducing flames; Principles of ——: detection of traces of manganese in the presence of iron or other substances. J. Meunier. Comptes rend., 1921, 172, 678—681.

WHEN an oxide or a salt, introduced into a flame, undergoes reduction, the reaction is manifested by

a line spectrum. If the oxide is not reduced the spectrum of the metal is not produced, but only a continuous spectrum of incandescence. It is necessary in many cases to use a hydrogen flame, as its reducing action is more energetic than that of a gas flame. In this method manganese is characterised by the triplet 4034·7, 4033·2, 4030·9 A. units, which is of extraordinary sensitiveness.—W. G.

Analysis; Physico-chemical volumetric ——. R. Dubrisay. Ann. Falsif., 1921, **14**, 9—18.

PHYSICAL methods for determining the end-point of titrations are discussed, those dealt with including electrical conductivity, surface tension, and cryoscopic measurements.—W. P. S.

Filter paper; Adsorption of lead and copper by —— *[in analysis]*. I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 152—159.

THE adsorption of lead from its solutions by filter paper is proportional to the alkalinity of the filter ash. With a high alkalinity nearly all the lead may be removed from a solution, whereas with a negligible alkalinity no appreciable adsorption takes place. On the other hand, the adsorption of copper from solution bears no relation to the alkalinity of the filter ash. From neutral solutions no adsorption takes place; from solutions in ammonia the adsorption is high, and it is greater with low concentrations than with higher ones. (*Cf.* J.C.S., April.)—W. J. W.

Adsorption; Importance of —— *in analytical chemistry. VII. Adsorption of silver, mercury, and other metals.* I. M. Kolthoff. Pharm. Weekblad, 1921, **58**, 233—241.

THE fixation of heavy metals is due to a chemical reaction with the ash of the cellulose, which is inhibited by acids. (*Cf.* J.C.S., April.)—S. I. L.

Microchemical analysis with reagents sensitised by saturation. E. Ludwig. Bul. Soc. Chim. România, 1920, **2**, 28—32.

THE reagent to be used is saturated with a salt containing the ion which is to be detected, the formation of a precipitate being observed under a microscope. The reagents recommended are $N/2$ silver nitrate saturated with sodium sulphate for the detection of sulphates; potassium pyroantimonate solution saturated with sodium chloride for the detection of sodium, and a solution of platinic chloride saturated with potassium chloride for the detection of potassium.—W. G.

Microchemical analysis with reagents sensitised by saturation. E. Ludwig and D. Butescu. Bul. Soc. Chim., România, 1920, **2**, 32—35. (*Cf.* preceding abstract.)

THE reagents recommended are $N/2$ silver nitrate treated with sodium acetate, until a precipitate just appears, for the detection of acetates; a solution of uranyl acetate saturated with a sodium salt for the detection of sodium. For the identification of borax a few particles are added to a drop of $N/2$ silver nitrate. Very small crystals soon begin to appear, and on warming the slide the undissolved particles become black.—W. G.

Sodium acetate method for the separation of the divalent metals from trivalent metals in the ammonium sulphide group. T. Sabalitschka. Ber. deuts. Pharm. Ges., 1921, **31**, 36—37.

THE sodium acetate method described by Macri (J., 1920, 804 A) for the separation of iron, chromium, and aluminium from zinc, manganese, etc., is useless in the presence of chromium, as this metal is not precipitated at all when alone, and only partially in presence of iron and aluminium. —G. F. M.

Potash; Centrifugal method for determining —— *[in molasses, etc.]*. E. Sherrill. J. Ind. Eng. Chem., 1921, **13**, 227—228.

FIVE c.c. of a solution of the sample, containing about 1% K_2O, is added to 17 c.c. of sodium cobaltinitrite solution, contained in a centrifuge tube; a similar mixture is prepared with 5 c.c. of 1·583% potassium chloride solution (=1% K_2O) and both mixtures are centrifuged for 1 min. at 1000 revs. per min. The tubes are then tapped with the finger to level the surface of the precipitate, again centrifuged for 15 secs., and the volumes of the precipitates noted. In the case of molasses, about 26 g. is dissolved in water, rendered alkaline with sodium hydroxide, acidified with acetic acid, diluted to 100 c.c., and 5 c.c. of this solution used for the determination. The sodium cobaltinitrite solution is prepared by adding 450 g. of sodium nitrite dissolved in 800 c.c. of water to 250 g. of cobalt acetate dissolved in 800 c.c. of water, and diluting the mixture to 2000 c.c; for use, 100 c.c. is mixed with 65 c.c. of water and 5 c.c. of glacial acetic acid. The acidified reagent does not keep well.—W. P. S.

Manganese; Interference of phosphates in the detection of —— *and its avoidance.* T. Sabalitschka and H. Niesemann. Ber. deuts. Pharm. Ges., 1921, **31**, 30—36. (*Cf.* J., 1921, 64 A.)

THE failure to detect manganese in presence of an excess of barium or strontium phosphate when the separation of phosphoric acid is conducted according to Schmidt's method is obviated by the following procedure:—The precipitate obtained with ammonium sulphide is dissolved in 5% hydrochloric acid and filtered from insoluble nickel and cobalt sulphides. The solution is evaporated with 2—3 g. of concentrated sulphuric acid and a like quantity of saturated potassium sulphate solution until white fumes are evolved, any ferrous iron being previously oxidised by nitric acid. The mixed sulphates obtained are extracted with alcohol to remove sulphuric and phosphoric acids (small quantities of manganese and zinc sulphates and most of the chromium also pass into solution). The residue insoluble in alcohol is extracted with dilute hydrochloric acid and the insoluble sulphates of barium, strontium, and calcium filtered off. From the filtrate, iron, aluminium, and chromium are precipitated with ammonia, and then the sulphides of zinc and manganese with ammonium sulphide. The final filtrate contains calcium and magnesium. —G. F. M.

Iron; Volumetric determination of ——*by titanous salts.* W. M. Thornton, jun., and J. E. Chapman. J. Amer. Chem. Soc., 1921, **43**, 91—102.

KNECHT and Hibbert's method (J., 1903, 232, 762) of estimating ferric iron by titration with a solution of a titanous salt using ammonium thiocyanate as indicator yields trustworthy results under the following conditions. The titanium solution (either chloride or sulphate) must be preserved under hydrogen both in the storage bottle and in the burette, and the titration must be carried out in an atmosphere of carbon dioxide and at a temperature not above 30° C. Not more than 500 c.c. of solution may be titrated and 10 c.c. of 10% solution of ammonium thiocyanate should be added. In presence of hydrofluoric acid the indicator gives only a yellow coloration, but if an excess of boric acid is added the red colour is produced and a perfectly sharp end point is obtainable. The titanous solution is standardised with ferrous ammonium sulphate which is exactly oxidised by potassium permanganate and then reduced with the titanous solution. Standard titanous solutions preserved as described maintain their titre indefinitely.—J. F. S.

Copper, antimony, and tin; Electro-analytical separation of ——. F. Foerster and D. Aanensen. Z. Elektrochem., 1921, 27, 10—16.

The solution containing copper, tin, and antimony is evaporated to dryness, treated with 5 c.c. of nitric acid (sp. gr. 1·4), 5 c.c. of 50% tartaric acid, and sufficient hydrogen peroxide to oxidise the tin, and made up to 40 c.c. with water. The solution is electrolysed, with thorough cooling, for 1 hr. with a current of 1·5 amp. in a Frary apparatus with a 5 amp. coil current. The copper deposit is removed with nitric acid and tartaric acid, and the copper re-deposited in the same manner. Since the first deposit contains no tin but only antimony as impurity, the two solutions after the second deposition of copper are not mixed, but each is neutralised with sodium hydroxide, treated with 50 c.c. of 10% oxalic acid, and treated hot with hydrogen sulphide. The two antimony precipitates are united, dissolved in alkali sulphide, and 30 c.c. of 30% potassium cyanide added. The solution is then electrolysed at 70° C. with 0·6 amp., using a Winkler net electrode. The deposition requires 2 hrs. for 0·1 g. of antimony, and the deposit is 1·8% heavier than the amount of antimony present. The solution containing the tin is concentrated, neutralised with 50% potassium hydroxide, made alkaline with 2 c.c. of 50% potassium hydroxide, treated with 1 c.c. of 3% hydrogen peroxide, boiled, and diluted to 150 c.c. The tin is deposited in 3½ hrs. at 80°—85° C. on a Winkler electrode with a current of 5 amp.; during the electrolysis 3 c.c. of 50% potassium hydroxide is added along with water to make good the loss by evaporation.—J. F. S.

Antimony and tin; Separation of —— *by hydrogen sulphide in hydrochloric acid solution.* G. Luff. Chem.-Zeit., 1921, 45, 229—231.

The different behaviour of antimony and tin sulphides in hydrochloric acid solution of varying concentration and at different temperatures was investigated. Precipitation of antimony sulphide begins at 80° C. when a solution of the two metals containing 30 c.c. of concentrated hydrochloric acid per 100 c.c. is treated with hydrogen sulphide; the tin sulphide remains in solution even at 25° C.
—W. P. S.

Tin and antimony; Separation of —— *in hydrochloric acid solution by means of hydrogen sulphide.* G. Luff. Chem.-Zeit., 1921, 45, 249—251, 254—255, 274. (*Cf. supra.*)

If hydrogen sulphide is passed into boiling solutions of antimony and tin salts, with addition of concentrated hydrochloric acid, increasing concentrations of the latter lower the temperature at which precipitation takes place on cooling. With an addition of 8, 14, and 30 c.c., respectively, to 100 c.c. of solution, the temperatures of precipitation were 102°, 102°, and 95° C. for antimony trisulphide; 102°, 100°, and 80° C. for the pentasulphide; and 90°—95°, 75°—80°, and 25° C. for stannic sulphide. Ammonium chloride still further lowers the temperature at which the sulphides separate; with 36 g. per 100 c.c. of solution the trisulphide and pentasulphide are precipitated at 78° and 60° C. respectively, whilst even at normal temperature no precipitation of the stannic sulphide occurs till after standing. The effect on the separation of the sulphides of varying concentrations of hydrochloric acid, in presence of a fixed amount (16·5%) of ammonium chloride, has been investigated. The cleanest separation takes place with 14 c.c. of hydrochloric acid (sp. gr. 1·193) per 100 c.c. of solution; the lowest effective amount is 8 c.c. per 100 c.c., and the maximum amount appears to be 35 c.c. per 65 c.c. of solution. For separating antimonious salts, Vortmann and Metzel's method (19·4 c.c. of hydrochloric acid) as well as modifications with 8 and 14 c.c., are all satisfactory. The Panajotow-Prim method (30 c.c.) gives sufficiently accurate results; when the ammonium chloride exceeds 16·5 g., however, the solution must be cooled in ice, and the introduction of hydrogen sulphide checked at 20° C., filtration being conducted at 5° C.—W. J. W.

Arsenic and phosphoric acids; Determination of —— *in presence of large quantities of salts.* L. Desbourdeaux. Bull. Sci. Pharmacol., 1920, 27, 225—240, 300—313, 363—372, 424—435. Chem. Zentr., 1921, 92, II., 475.

The ordinary methods for the determination of arsenic and phosphoric acids are not satisfactory when applied to solutions containing large quantities of alkali salts, such as are obtained by decomposition of organic substances, low in arsenic and phosphorus, with alkali nitrate and carbonate or with persulphate. Silver arsenate and phosphate are practically insoluble in a neutral solution containing ammonium salts and an excess of silver nitrate. The following procedure is, therefore, recommended. The solution, if not acid, is treated with 5—10 c.c. of strong nitric acid, then with sufficient silver nitrate solution to precipitate all the chloride, phosphate, and arsenate present and leave an excess of at least 2 g. of silver nitrate per litre of solution. The liquid is then carefully and exactly neutralised with ammonia, allowed to stand for ½ hr., and, if necessary, again brought to neutrality. Tests must be made on a spot plate, as indicators are precipitated by silver salts. The precipitate is filtered off, washed four times with 25 c.c. of 0·2% silver nitrate solution, and digested with a slight excess of a solution containing 40 c.c. of strong nitric acid and 4 g. of barium nitrate per litre to dissolve out the silver phosphate and arsenate and precipitate any adsorbed sulphate. After standing for 1 hr. the insoluble material is filtered off and washed with a solution containing 20 g. of strong nitric acid, 0·5 g. of barium nitrate, and 4 g. of silver nitrate per l.; the filtrate is exactly neutralised with ammonia as before, the precipitate collected in an alundum crucible, washed with 50—100 c.c. of 0·2% silver nitrate solution, then with distilled water till free from nitrates, dried at 150° C., then heated at 400°—500° C. to remove any ammonium nitrate, and weighed. Silica must be removed, if present, by evaporation of the solution of the first silver precipitate to dryness. If a large amount of chloride or any chromate is present the original solution is treated with caustic soda, boiled to expel any ammonia, cooled, and the arsenic and phosphoric acids precipitated by addition of a salt of an alkaline-earth metal. The precipitate is dissolved in nitric acid and precipitated with silver nitrate as described above.—A. R. P.

Arsenic; Detection of ——. L. W. Winkler. Pharm. Zentralh., 1921, 62, 125—128.

Three tests are described for the detection of small quantities of arsenic, namely, Bettendorf's test (use of stannous chloride dissolved in hydrochloric acid), a test in which arsine is detected by means of Nessler reagent, and a modification of the Gutzeit test, in which arsine is detected by the stain it gives on paper moistened with gold chloride solution. The Bettendorf test can be applied in the presence of sulphuric acid; in the case of dark-coloured solutions it is necessary to treat these with zinc and sulphuric acid, pass the evolved gases through hydrochloric acid, and test this for arsenic. Antimony, sulphur, and phosphorus compounds interfere with the Nessler reagent test, as they also produce precipitates.—W. P. S.

Arsenic; Determination of —— in organic compounds. G. R. Robertson. J. Amer. Chem. Soc., 1921, **43**, 182—185.

The compound is oxidised by digestion with a mixture of nitric and sulphuric acids (*cf.* Morgan, Organic compounds of arsenic and antimony, 1918, p. 349), the liquid is freed from nitrous compounds by means of ammonium sulphate, and the arsenic estimated by the iodometric method of Gooch, Browning, and Morris (Amer. J. Sci., 1900, **10**, 151). The results are quite comparable with those obtained by the Carius method.—W. G.

Tungsten; Analytical chemistry of ——. G. Fiorentino. Giorn. Chim. Ind. Appl., 1921, **3**, 56—58.

For volumetric estimation an ammoniacal solution of an alkali tungstate, which should not contain excess of alkali salts, or of hydrated tungstic acid, containing about 0·25 g. WO_3, is diluted to about 200 c.c., acidified with acetic acid, then rendered alkaline to the extent of one or two drops of ammonia solution, and boiled for a few minutes until a litmus paper in the solution becomes wine-red. To the boiling liquid, a measured volume, in excess, of standard lead acetate solution (32·6893 g. of the crystallised salt and 2 c.c. of acetic acid per 2 l.) is added, with continual stirring, boiling being continued until the flocculent precipitate becomes pulverulent or crystalline. Standard ammonium molybdate (7·485 g. of crystallised salt per l.) is then run into the boiling solution until a drop of the liquid gives a yellow coloration with a drop of a fresh solution of 0·1 g. of tannin in 10 c.c. of water. A blank test is carried out with 200 c.c. of water to ascertain the volume (usually 0·3 c.c.) of the molybdate solution necessary to yield a distinct yellow coloration with the tannin solution. Multiplication by 1·202 of the amount of lead precipitated by the tungstic acid gives the corresponding amount of WO_3. The reactions on which the method is based are $H_2WO_4+Pb(C_2H_3O_2)_2,3H_2O = PbWO_4+2C_2H_4O_2+3H_2O$, and $Mo_7O_{24}(NH_4)_6,4H_2O + 7Pb(C_2H_3O_2)_2,3H_2O = 7PbMoO_4+6NH_4.C_2H_3O_2+8C_2H_4O_2+21H_2O$. With an ore or concentrate, 1·5 g. is finely powdered and heated to 60° C. for 1 hr. with 100 c.c. of concentrated hydrochloric acid in a covered beaker. The beaker is then heated more strongly on a sand-bath, stirring being continuous for at least 30 mins. and afterwards occasional. When the liquid is reduced to about one-half its original volume 20 c.c. of nitric acid is added, and the liquid evaporated to about 25 c.c., 5 c.c. of nitric acid being then added and the liquid evaporated to 15—20 c.c. and mixed with about 180 c.c. of boiling water. After some hours the liquid is filtered and the precipitate washed by decantation with 1% nitric acid. If highly accurate results are not required the filter is returned to the beaker and the contents heated gently with 8—10 c.c. of concentrated ammonia solution and 25 c.c. of water until all the tungstic acid is dissolved; the undissolved residue should contain no black particles of undecomposed ore and should be whitish or but slightly coloured. With a poor ore the liquid containing the filter-paper is washed into a tall 350 c.c. beaker, the volume being made up to about 200 c.c. and the tungstic acid determined as above; with a rich ore the liquid is made up to a definite volume and an aliquot part taken so that the amount of WO_3 is about 0·25 g. If very exact results are required the filter is washed with the mixture of 8—10 c.c. of ammonia and 25 c.c. of water, the liquid being collected in the beaker containing the bulk of the precipitate. This beaker is then heated gently until all the tungstic acid is dissolved, the solution being filtered through the same filter, and the latter washed with very dilute ammonia solution. The solution is dealt with as described above, while the filter containing the residue is dried and calcined in a porcelain crucible at a moderate temperature, any tungstic acid it contains being estimated by the cinchonine method (see below); the later also admits of the estimation of the tin, which will be contained in the residue. The acid liquid from the original attack of the ore and from the washing may also be examined by concentration and precipitation with cinchonine, since if too little acid remains when the boiling water is added, part of the tungstic acid may be hydrolysed and pass into solution. The cinchonine gravimetric method is carried out as follows: About 1 g. of pure sodium hydroxide is fused with a trace of wood charcoal in a small iron crucible and, when the water has been expelled, allowed to cool. As soon as solidification occurs 0·5—1 g. of the tungsten ore is added, together with a little wood charcoal, the crucible is covered with an iron lid and heated gradually to dull redness, which is maintained for 8—10 mins. The fused mass is poured into a clean, dry iron or nickel dish floating on water, the crucible being freed from adherent material by gentle warming with water in a porcelain dish, into which also the solidified mass from the metal dish is introduced. The whole mass is dissolved by boiling, finally with addition of 4—5 g. of solid ammonium carbonate, and the liquid filtered, the filter being washed with water rendered slightly alkaline with sodium hydroxide. The filtrate is heated and made strongly acid by gradual addition of 30 c.c. of concentrated hydrochloric acid, boiled for a few minutes, mixed well with 8—10 c.c. of a solution of 30 g. of cinchonine in 50 c.c. of concentrated hydrochloric acid and 250 c.c. of water, allowed to stand for some hours and filtered through a filter containing a little pulped filter-paper, the precipitate being washed three or four times with dilute cinchonine solution (30 c.c. of the concentrated solution, 30 c.c. of concentrated hydrochloric acid, 1000 c.c. of water), and finally once only with cold water; in the filtrate the tin may be estimated by the Pearce-Low method. The filter and its contents are heated gently in the original precipitating beaker with 8—10 c.c. of ammonia solution and 25 c.c. of water, stirred to break lumps, filtered into a small beaker, and washed with hot water containing a little ammonia. The excess of the latter is expelled by heating and the liquid treated immediately with 2—3 drops of hydrochloric acid and 8—10 c.c. of the concentrated cinchonine solution and well stirred for some minutes. After 1—2 hrs. the liquid is filtered through an ashless filter containing a little pulped filter-paper and the precipitate washed as before with the dilute cinchonine solution and once with water, dried, ignited in a platinum crucible, and weighed as WO_3. If a very exact result is required the precipitate is treated with 1—2 drops of dilute sulphuric acid and a little hydrofluoric acid, the latter being then driven off, 1—2 drops of nitric acid added, and this and the sulphuric acid then expelled by heating; in this way any silica present is eliminated. Cinchonine may be recovered from liquors containing it by rendering them alkaline with ammonia.—T. H. P.

Patent List.

The dates given in this list are, in the case of Applications for Patents, those of application, and in the case of Complete Specifications accepted, those of the Official Journals in which the acceptance is announced. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the date given.

I.—GENERAL; PLANT; MACHINERY.

Applications.

Bain and Keith. Heating and drying apparatus. 9761. Apr. 2.

Bartmann. Grinding-mills, disintegrators, etc. 9367. Mar. 29.

Bomsel. Preventing incrustation or boiler scale. 10,086. Apr. 6.

Cannon. Furnaces or ovens. 9356. Mar. 29.

Cook. Chemical and physical synthesis. 9887. Apr. 4.

Dine and Sieff. Preparation for removing and preventing scale in boilers etc. 9677. Apr. 1.

Hartshorn. Grinding and mixing machines. 9345. Mar. 29.

Knoblauch. Tunnel kilns. 10,069. Apr. 5.

Laing and Nielsen. Treatment of gases or vapours etc. 9653. Mar. 31.

Laurick. Kneaders, mixers, etc. 10,453. Apr. 9.

McIntyre. Refining, mixing, etc. machines. 10,095. Apr. 6.

Mauss. Vacuum filters. 9931. Apr. 4.

Mohs. Grinding-mills. 9710. Apr. 1.

Vallez. Filter-presses. 10,177. Apr. 6. (U.S., 6.3.15.)

Withers (Etabl. C. H. Candlot Soc. Anon.). Grinding etc. mills. 9392. Mar. 29.

Complete Specifications Accepted.

29,651 (1919). Harris, and Whiteley and Sons. Drying machines of the travelling-apron type. (160,885.) Apr. 13.

32,121 (1919). Brinjes and Goodwin, Ltd., and Seaman. Roller grinding mills. (160,553.) Apr. 6.

1607 (1920). Corning Glass Works. Heat treatment of articles. (140,374.) Apr. 13.

12,618 (1920). Norske Akt. f. Elektrokemisk Industri. Manufacture of porous material. (143,500.) Apr. 13.

16,172 (1920). Metallbank u. Metallurgische Ges. Solidifying in fine powder liquids, pulpy masses, etc. (145,048.) Apr. 13.

18,967 (1920). Marks (Ore Roasting Development Co.). Treating solids capable of reaction with a gaseous reagent. (161,103.) Apr. 13.

19,290 (1920). Schmidt. Reaction towers. (147,213.) Apr. 13.

22,888 (1920). Barbet et Fils et Cie. Recovery of vapours of volatile liquids from air. (149,691.) Apr. 13.

24,174 (1920). Eberts. Drying apparatus. (160,717.) Apr. 6.

II.—FUEL; GAS; MINERAL OILS AND WAXES; DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Applications.

Baty. Process of gas purification. 9868. Apr. 4.

Baty, Cox, and Kerr. Gas purification. 10,230. Apr. 7.

Biddison. Combustible gas, and generation and burning of same. 10,132. Apr. 6. (U.S., 29.4.20.)

Black, Kime, and Lawson. Refining hydrocarbon oils, spirits, etc. 9436. Mar. 30.

Blumner. 9361. *See* III.

Bonnard. Carbonising furnaces or retorts. 9646. Mar. 31.

Bowen. Production of artificial fuel. 10,409. Apr. 8.

Brownlee. Synthetically-produced hydrocarbon oils. 9794. Apr. 2. (U.S., 13.5.18.)

Frentrup, Meyer, and Schubert. Manufacture of consistent fat, cart-grease, etc. from brown coal, peat, slate, paraffin, etc. 9487. Mar. 30.

Frentrup, Meyer, and Schubert. Obtaining components from brown coal, slate, etc. 9488. Mar. 30.

Igranic Electric Co. 10,302–3. *See* XXIII.

Macintosh. Destructive distillation of coal. 10,400. Apr. 8. (Australia, 8.4.20.)

Moncrieff. Retorts. 10,227–8, 10,334. Apr. 7 and 8.

Plauson's, Ltd. (Plauson). Manufacture of pastes or salves from mineral etc. oils. 10,084. Apr. 6.

Verity. Gas-producers. 10,410. Apr. 8.

Wade (Kliva Ges.). 9511. *See* XII.

Wilson. 9220. *See* III.

Complete Specifications Accepted.

32,236 (1919). Teague. Production of pure carbon. (160,561.) Apr. 6.

32,309 (1919). McComb. Converting liquid hydrocarbons into hydrocarbons of lower boiling point. (160,907.) Apr. 13.

2826, 2828, 2947 (1920). Ellis (Foundation Oven Corp.). Coke ovens. (160,625–6, 160,628.) Apr. 6.

7432 (1920). Hurez. Coke ovens. (153,272.) Apr. 13.

30,525 (1920). Klarding. Purifying blast-furnace and generator gases. (153,263.) Apr. 13.

III.—TAR AND TAR PRODUCTS.

Applications.

Blumner. Continual distillation of tars or oils. 9361. Mar. 29.

Wilson. Distillation of tars and oils. 9220. Mar. 29.

Complete Specifications Accepted.

15,651 (1920). Pestalozzi. Producing tar of aliphatic compounds or low-temperature tar. (145,408.) Apr. 6.

16,298 (1920). Wohl. Manufacture of phthalic anhydride. (145,071.) Apr. 6.

IV.—COLOURING MATTERS AND DYES.

Complete Specifications Accepted.

17,848 (1919). Morgan, and British Dyestuffs Corp. Manufacture of hydroxyazo dyes. (160,848.) Apr. 13.

19,392 (1919). Morgan, and Imperial Trust. Manufacture of arylsulphonyl and arylenedisulphonyl derivatives of 1.4-naphthylenediamine and its sulphonic acid. (160,853.) Apr. 13.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Applications.

Cassano. Production of cork board. 10,125. Apr. 6. (Ger., 30.4.20.)

Dreyfus. Manufacture of artificial threads. 10,036. Apr. 5.

Höchstädter. Metallised paper. 9323. Mar. 29.

Masterman. Manufacture of millboard etc. 10,187. Apr. 6.

Roper. Decottonising rags, carbonising cotton, etc. 10,343. Apr. 8.

Complete Specifications Accepted.

21,643 (1919). Bouffe. Production of artificial silk threads. (160,859.) Apr. 13.

25,502 (1919). Claessen. Treatment of wood or other substances containing cellulose to obtain cellulose and artificial resin, asphalt, lac, etc. (160,482.) Apr. 6.

25,788 (1919). Hawkins. Machines for washing wool etc. (160,485.) Apr. 6.

1930 (1920). Wells and Marx. Testing paper, board, textiles, etc. (160,619.) Apr. 6.

2999 (1920). Gahler. Producing fibre suitable for spinning from papyrus. (144,249.) Apr. 13.
18,945 (1920). Zellkoll Ges. Sizing paper pulp. (147,002.) Apr. 6.
18,949 (1920). Merckens. Sizing paper, pasteboard, etc. (147,006.) Apr. 13.
28,984 (1920). Glanzfäden A.-G. Producing spun material resembling wool or cotton from viscose solutions. (152,351.) Apr. 13.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Application.

Brandwood and Brandwood. Bleaching, dyeing, etc. textile fibres. 10,331. Apr. 8.

Complete Specification Accepted.

2890 (1920). Norweb. Fireproofing, metallising, and waterproofing lace and other fabrics. (160,627.) Apr. 6.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Applications.

Dossett. Crystallising copper sulphate. 9617. Mar. 31.
Ebbw Vale Steel, Iron, and Coal Co., and Thickins. Neutralising and drying sulphate of ammonia. 10,482. Apr. 9.

Wade (Kliva Ges.). Manufacture of fatty acids from hydrocarbons. 9511. Mar. 30.

Webster. Treating gaseous constituents of fatty oils, gums, resins, etc. 9434. Mar. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

29,001 (1919). Effront. *See* XVIII.

29,973 (1919). Chadbourne. Manufacture of saponaceous compositions. (160,892.) Apr. 13.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

APPLICATIONS.

Cooper. Washable waterproof water paint. 9543. Mar. 31.

Dehn (Satow). Manufacture of insoluble condensation product. 10,214. Apr. 6.

Parker. Metallic water paint. 9306. Mar. 29.

Webster. 9434. *See* XII.

COMPLETE SPECIFICATION ACCEPTED.

25,502 (1919). Claessen. *See* V.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

COMPLETE SPECIFICATION ACCEPTED.

29,172 (1919). Peachey and Skipsey. Obtaining vulcanised rubber goods and materials containing substances adversely affected by certain vulcanising processes. (160,499.) Apr. 6.

XV.—LEATHER; BONE; HORN; GLUE.

APPLICATION.

Plausons, Ltd. (Plauson). Manufacture of glue. 9762. Apr. 2.

COMPLETE SPECIFICATIONS ACCEPTED.

14,626 (1920). Elektro-Osmose A.-G. Process for tanning or impregnating materials. (143,921.) Apr. 13.

32,891 (1920). Lambeek. Making the colouring of natural horn water-resisting. (154,200.) Apr. 13.

XVI.—SOILS; FERTILISERS.

APPLICATIONS.

Lo Monaco. Chemical fertilisers. 10,315. Apr. 7.

Soc. l'Azote Français. Manufacture of fertilisers. 9372. Mar. 29. (Switz., 29.3.20.)

COMPLETE SPECIFICATION ACCEPTED.

12,495 (1919). Morel. Manufacture of assimilable phosphates. (160,847.) Apr. 13.

XVIII.—FERMENTATION INDUSTRIES.

COMPLETE SPECIFICATIONS ACCEPTED.

29,001 (1919). Effront. Manufacture of pressed yeast from distillers' grains, oil cake, etc. (160,496.) Apr. 6.

32,245 (1919). Townsend. Manufacture of fermented liquors. (160,562.) Apr. 6.

XIX.—FOODS; WATER PURIFICATION; SANITATION.

APPLICATIONS.

Adam and Gair. Removing oil from condensation waters. 10,310. Apr. 7. (Fr., 15.4.20.)

Dienst. Sterilising flour and grits from cereals. 9806. Apr. 2.

Fyers and Looker. Preservative treatment and refrigeration of fish. 9827. Apr. 2.

Green. Centrifugal sewage purification. 9776. Apr. 2.

Grün, and Schicht A.-G. Manufacture of butter fat and lard. 9652. Mar. 31. (Czecho-Slov., 1.4.20.)

Imperial Trust, and Piqué. Cooling and freezing fish etc. 9485. Mar. 30.

Mizusawa and Yamamoto. Preparing odourless and colourless oil and flour from beans. 9753. Apr. 1.

COMPLETE SPECIFICATIONS ACCEPTED.

7272 (1915). Wehner. Apparatus for separating gases, iron, manganese, etc. from water. Apr. 6.

31,354 (1919). Hawker. Insecticides, fungicides, animal dips, etc. (160,511.) Apr. 6.

570 (1920). McDougall and Howles. Sheep-dips and cattle-washes. (160,597.) Apr. 6.

21,856 (1920). Drayer and Hanson. Preserving eggs. (161,110.) Apr. 13.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

APPLICATIONS.

Farbw. vorm. Meister, Lucius, u. Brüning. Manufacture of dialkylaminoethyl-β-aracyl oxybutyric acid esters. 10,508. Apr. 9. (Ger., 10.4.20.)

Haddan (Jenny). Converting organic acids into esters. 9927–8. Apr. 4.

Plauson. 10,084. *See* II.

COMPLETE SPECIFICATIONS ACCEPTED.

20,021 (1919). Giertsen. Production of urea or ammonia from cyanamide. (160,857.) Apr. 13.

32,368 (1919). Darrasse Frères et Cie. Manufacture of valeric acid and alkali valerates. (137,061.) Apr. 13.

16,298 (1920). Wohl. *See* III.

17,780, 33,206–7 (1920). Kolshorn. Manufacture of derivatives of *p*-aminophenol and of its *o*-alkyl ethers. (145,614, 155,575–6.) Apr. 6.

29,956 (1920). Wacker Ges. f. Elektrochem. Ind. Manufacture of dichlorethylene. (156,080.) Apr. 13.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

APPLICATIONS.

Martinez. Colour photography and/or kinematography. 9993. Apr. 5.

Ott. Solution for coating kinematograph films etc. 10,202. Apr. 6.

COMPLETE SPECIFICATION ACCEPTED.

31,997 (1919) and 10,576 (1920). Greene, Thomson, and Colour Photography, Ltd. Colour photography. (160,540.) Apr. 6.

XXIII.—ANALYSIS.

APPLICATIONS.

Helps. Calorimeters. 10,323. Apr. 7.

Igranic Electric Co. (Cutler-Hammer Manuf. Co.). Measuring calorific value of combustible gases etc. 10,302–3. Apr. 7.

Krogh and Pedersen. Recording analysing apparatus for automatic analysis of gases. 9560. Mar. 30.

COMPLETE SPECIFICATIONS ACCEPTED.

19,518 (1919). Rodhe, and Svenska Akt. Mono. Gas-analysing apparatus. (160,854.) Apr. 13.

32,697 (1919). Davis and Rosling. Apparatus for analysing gases. (160,930.) Apr. 13.

2680 (1920). Svenska Akt. Mono. Gas-analysing apparatus. (138,355.) Apr. 13.

I.—GENERAL; PLANT; MACHINERY.

Evaporation, concentration, and desiccation of all organic or mineral substances; Process of ——. A. Sartory, L. Scheffler, P. Pellissier, and C. Vaucher. Comptes rend., 1921, 172, 744—746.

THE apparatus, which is sketched, is so arranged that the substance is submitted to a current of air deprived of moisture at a temperature near to 0° C., to avoid risk of change or decomposition of the substance being dried or of the liquid being evaporated or concentrated. The substance to be dried is placed in a box made of lattice-work, mounted on a shaft and rotated in the current of air. The air is first cooled below 0° C. to remove its moisture, and then warmed up to the temperature suitable for the substance under treatment. Thus to remove the water (80% by weight) from 15 kg. of fresh meat in 10 hrs. at 5° C., the air was first cooled to −8° C. to remove its moisture and then warmed to 5° C. This necessitated the passage of 1300 cub. m. of air per hr., the production of 9000 frigories per hr. for cooling the air to −8° C., and of 5000 cals. per hr. for subsequently warming it to 5° C.—W. G.

Refrigeration machines; Causes and prevention of the formation of non-condensable gases in ammonia absorption ——. E. C. McKelvy and A. Isaacs. U.S. Bureau of Standards, Techn. Paper No. 180, 25.10.20. 10 pages.

NON-CONDENSABLE gases in ammonia absorption refrigerating machines consist of nitrogen, hydrogen, and to a minor extent of oxygen. The presence of nitrogen is due to leaks of air into the system, and hydrogen when present is due to corrosive action of the liquid ammonia on the metal of the plant. Oxygen leaking into the plant is quickly used up. Impurities such as carbonates, acetates, and acetonitrile increase the corrosive action of ammonia liquor at ordinary operating temperatures to such an extent as to account readily for the hydrogen found in many plants. Where the quantity of carbonate present does not exceed 0·003%, the corrosive action of the liquor is not marked. For the determination of small quantities of carbonate in the ammonia solution, 100 g. of the latter is added to excess of sulphuric acid, the liberated carbon dioxide is absorbed in barium hydroxide solution, the precipitated barium carbonate washed and dissolved in hydrochloric acid, and the barium precipitated as sulphate. Gas formation due to corrosive action of the ammonia is prevented by adding 0·2% by weight of sodium or potassium bichromate to the generator charge.—J. S. G. T.

PATENTS.

Filter elements; Method of making —— [*for separating bacteria etc.*]. E. de Haën, Chem. Fabr. "List" G.m.b.H. E.P. 134,228, 23.10.19. Conv., 4.12.17.

A CELLULOSE ester is dissolved in a double solvent, volatile at ordinary temperature (*e.g.*, a mixture of acetone, chloroform, or ethyl acetate with glacial acetic acid, an alcohol, or an ether), and the solution, in the form of a thin layer, allowed to evaporate in a moist atmosphere, with or without previous addition of water to the solution. The air for evaporation may be circulated through an apparatus which removes the solvent and re-conditions the air as regards moisture content, and the film, which will be crinkly, may be flattened by stretching in hot water or steam.—B. M. V.

Pressure filters; Flushing apparatus for use with ——. *Filter-frame for use with pressure filters.* L. J. Martel, Assr. to Martel Filter Co., Inc. U.S.P. (A) 1,370,469 and (B) 1,370,470, 1.3.21. Appl., 11.3.20.

(A) AN oscillating spray pipe provided with a number of nozzles projects into the body of the filter to enable the filter cloths to be sprayed. The pipe is enclosed in a tubular sheath which normally covers the nozzles, but is slotted so as to expose the nozzles when the pipe is turned. (B) A filter-frame comprises a sheet-metal frame enclosing filter sheets of woven wire, the upper edge of the frame being formed as a strap through which a pipe for liquid supply passes, and supports the frame. The pipe is slotted longitudinally, and one of the wire sheets projects into the slot.—W. F. F.

Metallic filter gauze; Process for manufacturing ——. J. Rahtjen. G.P. 330,715, 15.1.19. Addn. to 329,061 (J., 1921, 203 A).

METAL gauze mixed with material such as cotton wool, wool, silk, linen, or nettle, ramie or similar fibre, is worked up into the form of filter cloth and is coated with a uniformly porous layer of metal by means of a metal-spraying device. The gauze is suitable for filtering oily and alcoholic liquors containing very small particles.—J. S. G. T.

Gas purifying apparatus. C. Bourdon. E.P. 139,758, 11.2.20. Conv., 6.3.19.

SOLID matter is removed from the gas by centrifuging, and is discharged into a torus-like passage formed by parts of the peripheral walls of the fan casing. A tubulure connects the inlet to the fan with a conduit conveying the gas to be purified, the conduit being arranged in the interior of a chimney shaft through which the purified gas is discharged into the atmosphere or delivered to apparatus where it is to be used. The gas can be short-circuited without purification, if desired, by means of a suitable valve.—A. G.

Dry cleaning [separating the solids from] gases and vapours, more especially furnace gases; Filter for ——. E. Dänhardt. E.P. 148,800, 10.7.20. Conv., 25.2.18.

FILTERS, which may be used at elevated temperatures, are constructed of metallic wires or perforated plates interwoven with mineral fibres, the surface of the latter being roughened, on the side upon which the gas impinges, by devices such as are used in the textile industry.—B. M. V.

Gases; Apparatus for separating dust and the like from ——. R. Boby, Ltd., and M. Jennings. E.P. 160,100, 27.5.20.

DUST-LADEN air or gas is caused to pass down and up several times inside a vertical container, the changes of direction being effected by domes or hoods provided with conical skirts, so that the passage for the gas gradually increases in cross-sectional area. The inlet pipe for the gas is at the centre and the outlet at the circumference of the container, and the separated dust is collected and drawn off at intervals. If desired, the gas may be divided into two or more streams by means of a short pipe or pipes inserted upwards into the bottom of the first downtake (inlet) pipe, the streams being kept apart by additional hoods and skirts till just before reaching the outlet.—B. M. V.

Gases or vapours; Process for treatment of —— *with liquids.* H. Roser. G.P. 330,071, 17.4.14.

INTIMATE mixing, efficient distribution and transportation of the gas or vapour and the liquid are

effected by introducing them into a vessel, formed somewhat similar to a hydraulic compressor, and connected with a fall tube.

Electrical separation of dust from gases and vapours; Apparatus for ——. A.-G. Brown, Boveri & Co. G.P. 331,143, 24.9.19.

In an apparatus consisting of a dust chamber in which electrodes of opposite polarity are arranged in rows, each electrode extends within a guiding framework to a width greater than the chamber, and can be displaced to either side for cleaning so that the part of the electrode within the chamber is changed from time to time.—C. I.

Grinding or crushing mills. H. Cramm. E.P. 145,599, 29.6.20. Conv., 15.5.14.

A rotating cylindrical drum is flattened in three or more places to give it a roughly polygonal section (with rounded angles), and is provided with a loose grinding roller of nearly the same length as the drum.—B. M. V.

Ball-mill. G. B. Allison, Assr. to G. H. Beesmyer. U.S.P. 1,370,259, 1.3.21. Appl., 4.2.20.

A horizontal rotating drum contains an inner concentric drum attached at one end to the end wall of the outer drum, and having a separate end wall at the other end spaced from the outer drum. The annular space between the drums is provided with a number of ball races side by side, with freely movable grinding balls. Ports are provided between the inner and outer drums, and hollow trunnions communicate respectively with the inner drum and the annular space.—W. F. F.

Boiling pans and mixing machines. J. MacLachlan, G. Stewart, and A. E. Clark. E.P. 159,924, 7.11.19.

One set of stirring and scraping gear may serve two or more boiling pans by supporting the former upon a radial arm which can be swung round a vertical column.—B. M. V.

Ring furnace and drying plant. A. E. H. Beyer. E.P. 160,328, 16.1.20.

In a combined ring furnace and drying plant the conduits between the separate divisions of the furnace and the individual chambers of the drying apparatus and the chimney are so arranged that air may be caused to flow from any one division of the furnace through any one chamber, or *vice versâ*, and thence to the chimney; or from any one division of the furnace or chamber to the chimney, either direct or through another division or chamber.—H. H.

Furnace. J. U. McDonald. U.S.P. 1,370,139, 1.3.21. Appl., 7.9.20.

A crucible furnace is provided with a bottom sloping towards the front, and with an arched top having openings to admit crucibles. A fuel-supply pipe extends through the front wall, and the rear wall has a ridge extending forward to cause the combustion products to divide and pass along the two side walls.—W. F. F.

Furnace or oven. H. B. Cannon. U.S.P. (A) 1,371,773 and (B) 1,371,774, 15.3.21. Appl., 29.3.20.

(A) An oven has a space for subjecting articles to radiant heat and a combustion chamber in operative relation to such space, but not communicating therewith, the combustion chamber being formed principally of carborundum. (B) A combustion chamber is provided, intermediate of its height, with a partition extending from the front towards and spaced from the rear, the top of the chamber being provided with an outlet near the front. The chamber is formed principally of carborundum, and means are provided for supplying a combustible mixture into the front of the chamber beneath the partition.—H. H.

Dissolving, crystallising, and calcining apparatus; Combined ——. A. Roy, Assr. to J. L. Sharkey. U.S.P. 1,369,840, 1.3.21. Appl., 12.12.18.

Dissolving, crystallising, drying and calcining chambers are arranged in series. A heating medium is supplied to the calcining chamber, and the excess of heat is utilised successively in the drying, crystallising, and dissolving chambers.—W. F. F.

Continuous solution, washing or lixivation of salts; Apparatus for the ——. H. Pappée. G.P. 327,687, 20.9.18.

A filter bed composed of fine-grained material, such as sand, is disposed immediately beneath the vessel containing the solution to be treated. The surface of the filter bed is funnel-shaped, the apex being directed downwards, and a number of spaced overlapping plates are laid thereon. A number of sliding bars extending from top to bottom of the funnel-shaped surface form a grid with the plates. An archimedean screw arranged within a tube extending upwards from the apex of the funnel serves to remove any residue from the filter bed. The device can be operated with the formation of very little sludge.—J. S. G. T.

Centrifugal clarifier. M. Leitch, Assr. to The De Laval Separator Co. U.S.P. 1,370,326, 1.3.21. Appl., 19.8.19.

Liquid is delivered into the top of a rotating vertical vessel having a contracted central opening at the bottom, from which it passes to an outer containing vessel which also rotates and in which the liquid is subjected to a greater centrifugal force. —W. F. F.

Desiccating-machine. G. C. Contant, Assr. to J. Decker, jun. U.S.P. 1,371,071, 8.3.21. Appl., 18.7.19.

A travelling metallic belt is arranged within a partly exhausted container, the material to be desiccated being directed on to the upper run of the belt, and heating devices being disposed below and almost in contact with both upper and lower runs. —H. H.

Evaporator. T. M. Pusey. U.S.P. 1,371,115, 8.3.21. Appl., 18.9.19.

An evaporating vessel is supported in a structure which forms a receptacle at the bottom thereof for a fluid heating medium. External to the vessel, but within the structure, are circulating means, connected with the bottom of the vessel for the downflow of the fluid contents of the vessel, and also connected with the vessel above the bottom for the return of the fluid thereto.—H. H.

Evaporator. J. C. Grière. U.S.P. 1,371,784, 15.3.21. Appl., 24.8.20.

Two evaporating vessels are connected by a conduit in which is a chamber from which steam is returned to the first vessel. A second chamber in the conduit is in communication at its top and bottom with the top and bottom, respectively, of the second vessel, and this chamber contains a continuous spiral passage with perforated transverse partitions. A valve between the two chambers is controlled by the height of the fluid in the first chamber.—W. J. W.

Refrigerating system, and method of operating the same. G. A. Gase and E. A. Seymer. U.S.P. 1,371,235, 15.3.21. Appl., 8.1.17.

In a method of refrigeration in which a refrigerating medium is liquefied with evolution of heat at

one portion of a closed system and vaporised with absorption of heat at another portion, a pressure is maintained in the system by an inert gas in order to control the absorption of heat.—H. H.

Solvent-recovery apparatus. W. K. Lewis and W. Green. U.S.P. 1,371,914, 15.3.21. Appl., 8.5.19.

An apparatus for removing and recovering a volatile inflammable solvent from a material containing it comprises a drying chamber, means for supporting the material in the chamber, a burner, means for conducting flue gas from the burner into the chamber to take up the vapour of the solvent, means for cleaning the flue gas on its way to the chamber, and means for recovering the solvent from the gas leaving the chamber.—H. H.

Volatile solvents; Removal of —— from material treated therewith. H. Bollmann. U.S.P. 1,371,546, 15.3.21. Appl., 9.12.19.

See E.P. 154,044 of 1919; J., 1921, 33 A.

Condensers and boilers; Disincrustant for cleaning ——. J. Urruty, Assr. to Urruty et Cie. U.S.P. 1,371,584, 15.3.21. Appl., 11.12.18.

See E.P. 121,590 of 1918; J., 1919, 704 A.

Furnace; Rotary ——. F. Derneden. U.S.P. 1,372,406, 22.3.21. Appl., 16.9.19.

See E.P. 156,835 of 1919; J., 1921, 169 A.

Furnaces [; Tilting ——]. A. Imbery. E.P. 160,247, 15.12.19.

Density of liquids; Apparatus for indicating the —— and automatically grading the same according to their density. J. L. Mennell, and C. Butters and Co., Ltd. E.P. 160,293, 24.12.19.

Grinding mills; [Mounting and adjusting rollers in] roller ——. Brinjes and Goodwin, Ltd., and C. J. Seaman. E.P. 160,553, 22.12.19.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

Coal; Determination of heat of carbonisation of —— in the calorimeter. H. Strache and H. Grau. Brennstoff-Chem., 1921, 2, 97—99.

Otto (Diss., Breslau, 1914) determined the heat of coking by using an electric resistance furnace embedded in asbestos in an iron vessel, the furnace being kept at a constant temperature and a steady temperature gradient being maintained by immersing the iron vessel in a cold water bath at constant temperature. The fall in temperature of the oven after introduction of the coal charge is compensated for by extra current input, and the energy required for this purpose is measured, and from it the heat of coking is calculated. By this method the gross heat of carbonisation (referred to water and tar at 0° C.) of a certain coal was found to be 260 cals. per g. Grau has determined this value directly by carbonising 1 g. of coal in a copper cylinder, fitting into a quartz tube furnace, wound with constantan, the whole being contained in a Berthelot-Mahler bomb which was filled with nitrogen at the commencement of the experiment. The temperature was measured by means of an iron-constantan couple. A temperature of 700° C. was attained in 10 mins. and current and voltage at the furnace terminals were measured every 15—20 seconds. Values are quoted for coals, brown coals, lignites, wood, and cellulose ranging from 8 cals. per g. (absorbed) for coal with 26·27% of volatile matter to 265 cals. per g. (evolved) for beech wood with 76·94% of volatile matter. The gross heat of carbonisation seems to be proportional to the oxygen content of the coal.—A. G.

Coal and other solid fuels; Oxidation of —— under pressure. F. Fischer and H. Schrader. Ges. Abhandl. Kennt. Kohle, 1919, 4, 342—359. Chem. Zentr., 1921, 92, II., 422.

The percentages of fuel converted into oxidation products by a pressure oxidation for 3 hrs. at 200° C. in presence of sodium carbonate solution reached, for older coals 10%, for younger coals above 30%, for lignite and peat above 90%, for wood 75%, and for cellulose almost 100%. Only a moderate proportion was converted into carbon dioxide. Humic acids, clear oily acids, higher and lower fatty acids, and oxalic acid were obtained. The oily acids contained aromatic compounds, for when distilled some phthalic anhydride was obtained. No mellitic acid was obtained. Insoluble humic acids of high molecular weight, which form the first stage of oxidation of a portion of coal and wood substance and also are present in lignites and peat, are transformed first into more soluble though still dark-coloured humic acids and then into lighter-coloured acids of progressively smaller molecular weight. Wood such as box and fir yielded humic acids, but pure cellulose none.—H. J. H.

"Oilcoals" [deposits in internal combustion engines etc.]; Composition and formation of ——. J. Marcusson. Brennstoff-Chem., 1921, 2, 103—104.

The author gives the name "oilcoal" to the carbonaceous deposits formed in internal combustion engines, compressors, steam engines, etc. Such deposits generally consist of an oily portion soluble in benzine, a brittle asphaltic constituent insoluble in benzine, a coaly portion, and mineral ash. The coaly portion, which has previously been considered as insoluble in organic solvents, has been shown by the author to be soluble if a large quantity of solvent is used. Asphaltogenic acids or their anhydrides were separated from the solution and the residue consisted of "carbenes" or "carboids" (products of oxidation of mineral oil). A deposit occurring in a hydrogen compressor consisted of 6% of oil soluble in benzine, 8% of a black solid material (half of which was saponifiable), soluble in chloroform, and 86% of material insoluble in chloroform. The 27% of ash contained tin oxide and sodium carbonate. The theory advanced is that, by previous long use of the oil, resinification and the formation of asphaltenes, carbenes, and asphaltic acids has taken place. These acids have attacked the metal with the formation of tin soaps. At the same time an increase in the amount of alkali soap present in the oil has taken place. This accounts for the presence of alkali carbonate in the ash of the deposit.—A. G.

Coal gas and coke-oven gas; Determination of benzene hydrocarbons in ——. E. Berl, K. Andress, and W. Müller. Z. angew. Chem., 1921, 34, 125—127.

A layer of dry charcoal is placed in a U-tube which is provided with gas inlet and outlet tubes and taps. A current of gas is then passed over the charcoal at a rate which depends on its content of benzene hydrocarbons, but is approximately 250 l. per hr. When absorption is complete, the U-tube is connected at one end with a steam supply and at the other end with a condenser and measuring burette; the tube is heated in a bath to about 110°—120° C., and steam is passed through for ½ hr., the distilled hydrocarbons being measured in a burette. The method gives more accurate results than the freezing, paraffin oil, and dinitrobenzene methods, and is further applicable,

where the above are unsuitable, in cases where there is only a small amount of benzene hydrocarbons present.—W. J. W.

Paraffin wax; Pressure oxidation of ——. F. Fischer. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 35—47. Chem. Zentr., 1921, **92**, II., 377.

The oxidation was conducted in a horizontal autoclave provided with an agitator, 200 g. of hard paraffin wax being heated to 170° C., while a current of air at 30 atm. pressure (200 l. per hr.) was passed through. 800 c.c. of 2·5*N* sodium carbonate solution was present, and oxidation was continued until one half of this was neutralised by the fatty acids formed. The residue was not pure paraffin wax. Fatty acids of average molecular weight 250, insoluble in water and suitable for soap making, were obtained. Acids soluble in water were also produced and a considerable quantity of carbon dioxide. The sodium salts of the higher acids suffer some decomposition during the reaction. Some light paraffin oils were obtained.

—H. J. H.

Pressure oxidation of paraffin wax; Influence of various factors during the ——. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 48—93. Chem. Zentr., 1921, **92**, II., 377—378.

The influence of various factors was ascertained by variation of the conditions of the normal experiment described in the preceding abstract. The degree of filling of the autoclave was important. Rise of temperature affected the colour of the products as well as the speed of oxidation. Quantity of air influenced the molecular weight of the acids. Increase of air pressure caused acceleration of the reaction. Undue prolongation of the oxidation caused a secondary decomposition of the acids produced. Speed of stirring, quantity and concentration of alkali had little influence. The use of lime as base was found undesirable. The quantity of paraffin influenced the colour and yield of acids. Iron, manganese, and copper were the best catalysts, but cerium, titanium, fuller's earth, and charcoal gave products with the best colour. The addition of toluene and xylene improved the yield of solid fatty acids, although neither of these solvents, in the absence of paraffins, is oxidised under the experimental conditions. When the apparatus was lined with glass or lead the reaction was retarded and the colour of the product improved. Paraffins obtained from lignite, coal, peat, or mineral oil are all suitable for pressure oxidation, although the first two are more resistant. Paraffin oils yielded liquid acids insoluble in water. In the absence of alkalis paraffin wax was more extensively oxidised than in their presence. The yield of fatty acids was 74% of the paraffin consumed, but their colour was dark brown.—H. J. H.

Paraffin wax; By-products of the pressure oxidation of ——. W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 101—117. Chem. Zentr., 1921, **92**, II., 378—379.

In the treatment of the product obtained in oxidation experiments such as described in the preceding abstracts, the cake of unchanged paraffin was separated and the residue worked up to a solid soap. The presence of water-soluble salts of lower fatty acids in the crude product would, if these were not removed, render the soap hygroscopic and impart a disagreeable odour. The solution of salts of lower acids, however, lathers well, and such solutions are suitable for the laundry and scouring purposes. The soda solution of these acids was filtered off from the insoluble salts and evaporated to dryness. The residue contained 1% of neutral material soluble in benzene, and 54% of fatty acid salts, equivalent to 46% of fatty acids. Half were insoluble in water, ranging from capric to lauric acids, the rest of the acids being soluble. Some oils separated on cooling the compressed air after leaving the autoclave. None boiled below 150°, and 67% between 150° and 250° C. Neutral substances containing oxygen, *e.g.*, alcohols, aldehydes, and ketones, were present. Solid substances, of similar chemical character, also containing oxygen, were found in the cake of residual unoxidised paraffin. The liquid portions had a fruity smell, while the solid portion resembled a true wax rather than paraffin.—H. J. H.

Paraffin wax; Treatment of the acids obtained in the pressure oxidation of ——. W. Schneider and A. Jantsch. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 118—130. Chem. Zentr., 1921, **92**, II., 379.

The oxidation products of paraffin obtained as described in the preceding abstracts were examined with a view to identifying the acids. To effect a separation the ethyl esters were prepared. The acids conformed to the general formula $C_nH_{2n}O_2$, but the presence of hydroxy-, keto-, and dibasic acids could not be established. For the acids identified the values of *n* were 19, 17, 15, and 13, the odd numbers of carbon atoms being predominant. On the other hand, in fats and oils the acids have mainly an even number of carbon atoms.

—H. J. H.

Paraffin wax; Oxidation of —— by air at ordinary pressure. W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 132—142. Chem. Zentr., 1921, **92**, II., 376—377.

Experiments on the oxidation of paraffin wax were made in glass and iron vessels. The yield of fatty acids insoluble in water was only 2—3% in glass vessels, but 64% in iron. Mercuric oxide had no catalytic effect. The formation of acid anhydrides is indicated by the presence of products soluble in hot sodium hydroxide solution, but insoluble in sodium carbonate. The reaction velocity is very much smaller than when pressure is employed.

—H. J. H.

Montan wax; Pressure oxidation of ——. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1919, **4**, 180—209. Chem. Zentr., 1921, **92**, II., 376. (*Cf.* Fischer and Tropsch, J., 1920, 55 A.)

Pressure oxidation experiments with air made on crude montan wax, with and without a preliminary saponification, indicated that a degradation to medium and lower fatty acids occurred, although montan wax is distinctly more inert in this respect than paraffin wax. The soaps obtained from the reaction products did not lather so well as those derived from paraffin. The yield was also lower. Fatty acids once formed are rapidly broken down, thus accentuating the poor yield.—H. J. H.

Montan wax. Schneider and Jantsch. *See* III.

Simmance calorimeter. Gray and Blackie. *See* XXIII.

Patents.

Peat fuel; Preparation of —— for producer or other gas for power purposes. S. C. Davidson. E.P. 159,996, 11.12.19.

A portion of the peat is taken straight from the bog and is worked up to a putty-like consistency. It is then blended with a proportion of powdered dry peat and slaked lime and pressed into blocks.

—A. G.

Artificial fuel; Manufacture of ——. J. W. Leadbeater. E.P. 160,042, 17.1.20.

BLACK peat, straight from the bog, is finely disintegrated and mixed with ground caustic lime, with finely ground and dried pitch or tar, or both, and with a tar or mineral or fuel oil or fatty oils or a combination of two or more of such oils, to which mixture is added finely ground coal.—A. G.

Briquettes; Coal or like —— *and the manufacture thereof.* A. A. Dale. E.P. 160,279, 18.12.19.

COAL is finely ground together with about 10% of lime or other alkaline-earth oxide in water. The mixture is allowed to stand out of contact with atmospheric or other carbon dioxide until hydration is complete and the mass is then briquetted. Ferric oxide or manganese oxide may be added to the extent of 0·5% or 1·0% to promote combustion. In order to render the briquettes weatherproof they may be dipped in sodium silicate solution. —A. G.

Pulverised fuel furnaces. J. E. Kennedy. E.P. 144,724, 11.6.20. Conv., 9.3.18.

THE relatively long combustion chamber of the furnace has parallel longitudinal walls and no internal obstructions. The air blast carrying the pulverised fuel enters the combustion chamber centrally and in a direction parallel to the longitudinal walls, the fuel supply nozzle extending within the combustion chamber. The combusion chamber is completely open to the atmosphere at the air blast inlet end. —A. G.

Shaft furnace for fuels rich in water and gas. R. Bergmans. G.P. 330,183, 13.11.18.

THE upper part of the shaft is divided so as to form one chamber where fresh fuel is carbonised and another where the gas produced is burnt, the latter communicating with the gas off-take main. —H. J. H.

Coke or carbon; Separation of —— *from slag or the like.* Soc. "Le Coke Industrielle." E.P. 156,562, 10.6.20. Conv., 7.1.20. Addn. to 120,932 (J., 1919, 672 A).

THE separating compartments described in the original patent are adjustable at any angle by means of joints and slides, for the purpose of adjusting the sizes of the openings through which the ascending currents of water rise. The inlet pipes for the ascending currents of water comprise concentric tubes, the inner tube being provided with orifices of decreasing size communicating with the outer tube, which is provided with small holes of equal size communicating with the respective separating compartment. The outer plate is a grating contiguous with which is a straight or curved perforated plate. —A. G.

Coke oven. C. E. Lucke, Assr. to L. and A. A. Wilputte. U.S.P. 1,371,315, 15.3.21. Appl., 30.8.17. Renewed 13.8.20.

A REGENERATIVE coke oven has parallel horizontal coking chambers, with heating walls between the chambers, and in each heating wall two groups of heating flues and an upper horizontal passage to which the upper end of each of the flues in both groups is connected. A set of regenerators runs transversely to, and beneath the chambers and heating walls to which the lower ends of the flues in one group of each of the various heating walls are connected, and another set of similarly located regenerators is connected with the lower ends of the remaining flues, each regenerator being connected with a part only of the flues in the group of each heating wall with which the corresponding set of regenerators is connected. Separate waste gas outlet channels, running parallel to the regenerators, are provided for the various regenerators, and also a common stack flue with which these channels are individually connected at the end of the oven.—A. G.

Gas manufacture. E. V. Hayes-Gratze. E.P. 160,202, 10.7.20.

THE material to be carbonised is fed through a number of tubes heated by the exhaust gases of an internal combustion engine.—A. G.

Purifying gas; Material for ——. *Material for purifying gas and process for manufacturing the same.* J. E. Hutchinson, Assr. to J. F. Henderson. U.S.P. (A) 1,370,494 and (B) 1,370,495, 1.3.21. Appl., (A) 8.12.19, and (B) 15.2.19. (B) Renewed 27.8.20.

(A) THE purifying material consists of a porous mass, the surface of the pores being coated with the absorbent. (B) The material is made by incorporating hydrated ferric oxide with silica and cement to form a porous concrete.—A. G.

Heating-value indicator for illuminating gas. E. J. Brady, Assr. to U. G. I. Contracting Co. U.S.P. 1,370,945, 8.3.21. Appl., 29.7.19.

A HEATING-VALUE indicator for gas comprises a burner provided with a tip and a fuel inlet, and closed to the atmosphere between the inlet and tip. Means are provided for supplying a mixture of air and gas at the fuel inlet in changing ratio, and for ascertaining the air : gas ratio of the mixture such that the luminous tip of the flame at the burner ceases to exist. (*Cf.* J., 1919, 938 A.)—J. S. G. T.

Oil from oleiferous sandstone, shale, or the like; Apparatus for the extraction of ——. T. H. Oswald and A. D. Dixon-Brown. E.P. 160,114, 7.7.20.

THE material is charged by means of a screw conveyor into one end of a rotating cylindrical still provided in the interior with radial fins, and passes down the still, which is slightly inclined to the horizontal, to the lower end, whence it is removed by another screw conveyor to an outlet pipe dipping into a water-seal. Superheated steam passes into the still at the lower end through the hollow centre of the screw conveyor, and leaves the apparatus together with the products of distillation through a similar opening at the upper end.—L. A. C.

Bituminous shale; Process for treating ——. J. H. Ginet. U.S.P. 1,371,160, 8.3.21. Appl., 31.10.19.

THE shale is finely ground and is showered into a heated retort for the entire period necessary to distil all of the volatilisable products.—A. G.

Hydrocarbon oils; Cracking of ——. R. C. Holmes and F. T. Manley. E.P. 160,200, 8.10.19.

EACH still in a series of vertical cracking stills is heated by furnace gases over the middle portion of its height, and is provided with rotating scrapers to remove carbon deposits from the interior. Valved outlets are attached to the bottom of the stills for withdrawing residual oil, which passes through a heat exchanger to preheat the inflowing oil, and the stills are connected in series at the top by two sets of pipes at different levels to equalise respectively the level of the oil and the vapour pressure in the stills. The oil is pumped into the bottom of the first still, and vapour passes from the last of the series into an air condenser, which returns condensed liquid to the first still, and thence into a water condenser. The pressure within the apparatus is maintained at about 150—200 lb. per sq. in. by a regulator attached to the end of the water condenser.—L. A. C.

Hydrocarbons; Converting heavy into lighter ——. L. W. Goold. From Universal Oil Products Co. E.P. 160,236, 12.12.19.

OIL, *e.g.*, gas oil from Kansas or Oklahoma crude oil, is pumped through horizontal tubes of 4 in. diam., heated to 750°—860° F. (400°—460° C.), and thence into horizontal expansion tubes of 10 in. diam. The residual oil is withdrawn from the latter tubes at such a rate that the tubes are kept about half full, and the vapour passes to an air condenser, which returns condensed oil to the heating tubes, and thence to a water condenser. The oil during the whole of the treatment is maintained under a pressure of about 100 lb. per sq. in. —L. A. C.

Material [petroleum hydrocarbons]; Apparatus and process for treating —— in the gaseous phase. C. S. Davis, Assr. to M. C. Ernsberger. U.S.P. 1,369,787–8, 1.3.21. Appl., 30.4 and 13.7.17.

THE material passes through an atomiser into the lower end of a vertical retort maintained at a "temperature of dissociation," and containing a drum device spaced from the sides of the retort to provide an annular chamber through which the vapours pass to the outlet. Means are provided "to stir the vapours" as they pass through the retort. —L. A. C.

Hydrocarbons; Art of cracking ——. J. W. Coast, jun., Assr. to The Process Co. U.S.P. 1,370,881, 8.3.21. Appl., 27.9.17.

A BODY of oil is heated under pressure in a horizontal still heated at the bottom, and the vapour is condensed. Oil from the bottom of the still is passed through a filter to remove coke-forming matter, and then returned to the bulk of the liquid, the process taking place within the still to prevent cooling of the oil.—L. A. C.

Oils; Cracking ——. W. O. Snelling. U.S.P. 1,371,268, 15.3.21. Appl., 15.10.13.

THE vapour generated by a body of oil maintained at a cracking temperature is kept in contact with the oil and at one time during the period of treatment is subjected to external pressure to cause compression and condensation of a portion of the vapour.—L. A. C.

Gas-producer. W. Climie, Assr. to Chapman Engineering Co. Reissue 15,057, 8.3.21, of U.S.P. 1,040,148, 1.10.12. Appl., 12.4.20.

Gas analysing apparatus. E.P. 106,265. *See* XXIII.

IIB.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

PATENTS.

Distillation furnaces. G. Heeley. E.P. 159,908, 18.9.19.

THE vertical combustion flues of the furnace are arranged between the distillation chambers and a regenerator is situated below the latter. The combustion gas flues and air flues of the regenerator are each situated between two waste gas flues, all the regenerator flues being arranged perpendicularly to the length of the distillation chamber. In this way each of them communicates with all the combustion flues, whereby the whole regenerator is kept working continuously, even when one or more of the distillation chambers are wholly shut down. —A. G.

Decolorising carbon; Preparation of an active ——. Zellstoff-fabr. Waldhof. G.P. 330,942, 25.12.19. Addn. to 309,155 (J., 1920, 479 A).

THE residues from the hydrolysis of cellulose are extracted, before carbonisation, with solvents which dissolve resins, *e.g.*, alkaline solutions, hydrocarbons, alcohols, or ketones.—L. A. C.

Pyroligneous liquids from the carbonisation of wood; Treatment of ——. E. A. Barbet. U.S.P. 1,371,461, 15.3.21. Appl., 14.10.18.

IN the destructive distillation of woody material the tar is continuously removed from the vapours whilst these are at a temperature above the condensation point of acetic acid at the existing pressure. The remaining gases are cooled to condense the pyroligneous acid and are scrubbed to remove the last of the methyl alcohol and to leave a combustible gas suitable for use as a fuel. The wash liquor and crude pyroligneous acid are heated to obtain methyl alcohol vapour, which vapour is washed with an alkali to remove acids therefrom, and then again condensed. The crude acid liquor from which the methyl alcohol has been distilled is continuously boiled, the vapours being brought into contact with alkaline liquor to produce an acetate liquor which is passed through a water-insoluble liquid capable of dissolving tarry matter therefrom.—A. G.

Arc lamp electrodes. Planiawerke A.-G. für Kohlenfabrikation. E.P. 16,364, 19.11.15. Conv., 31.12.14.

PASSAGES or apertures are provided in arc lamp electrodes into which beads formed by the fusion of salts or metals incorporated in the electrodes for the purpose of enhancing the light-giving power of the arc, are drawn and retained by capillary forces, whereby the salts may be completely utilised and the formation of beads or slag upon the crater prevented.—J. S. G. T.

Vacuum tube. Ges. für drahtlose Telegraphie. G.P. 331,414, 22.9.18.

THE electrodes are composed of an alloy of iron and nickel, chromium, or cobalt, melted *in vacuo*. Such alloys are more easily worked and are stronger than chemically pure iron at the high temperatures at which the tube is operated.—J. S. G. T.

Incandescence gas mantles. South Metropolitan Gas Co., and C. J. D. Gair. E.P. 160,040, 15.1.20.

AN incandescence gas mantle yielding a light more closely approximating to daylight than that afforded by the usual type of mantle is prepared by using a mixture of substantially pure thoria with 0·2—0·4% of ceria.—J. S. G. T.

Pyroligneous liquids; Process for removing the tar from ——. E. A. Barbet. U.S.P. 1,371,460, 15.3.21. Appl., 14.10.18.

Tungsten-silicon alloy. E.P. 160,373. *See* X.

III.—TAR AND TAR PRODUCTS.

Low-temperature coal tar and its fractions; Oxidation of —— under pressure. F. Fischer and U. Ehrhardt. Ges. Abhandl. Kennt. Kohle, 1919, 4, 280—292. Chem. Zentr., 1921, 92, II., 422—423.

LOW-TEMPERATURE coal tar and also the fraction distilling below 270° C. were subjected to pressure oxidation in a continuous stream of air at 150° C. and 40 atm. pressure. The results left it uncertain whether the hydrocarbons as well as the phenols were oxidised. The product was a black lustrous pitchy

product partly soluble in benzene. The oxidation product of the hydrocarbons separately treated contained a clear, limpid oil and also a reddish-yellow oil which deposited solids when cooled, and dried in air like varnish. The hydrocarbons were thus attacked, although to a lesser extent than the phenols. In an experiment on the oxidation of the tar fraction up to 270° C., the hydrocarbons were scarcely attacked at 100°, whereas the phenols were extensively changed into resins and acids. Lead oxide was found to have no catalytic effect, and the experiment throws light on the behaviour of lead phenolate paints. The lead phenolate, partly by hydrolysis and partly by the action of carbon dioxide, is slowly decomposed, forming free phenol, which is slowly oxidised. It seems probable that the oxidation products of low-temperature tar are suitable for use as paints and varnishes.—H. J. H.

Lignite tar oils; Pressure oxidation of ——. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1918, 4, 143—162. Chem. Zentr., 1921, 92, II., 375.

Lignite tar oils when treated with air under pressure are appreciably oxidised at and above 100°, but not at 50° C. The product is partly a tough solid mass and partly an oil, which when distilled in steam yields an almost colourless and odourless distillate changing little in appearance on standing in air. If the oxidation is conducted in presence of alkalis scarcely any of the black pitchy material otherwise formed, is produced, but salts are formed from which the acids can be precipitated as viscid liquids with a pungent smell. These acids are insoluble in petroleum ether and have a sp. gr. greater than 1. The acid products melt with decomposition at 195° and resemble the poly-naphthenic acids described by Charitschkoff. —H. J. H.

Lignite tar oils; Possibility of purifying —— by pressure oxidation. F. Fischer and W. Schneider. Ges. Abhandl. Kennt. Kohle, 1918, 4, 163—179. Chem. Zentr., 1921, 92, II., 375.

The purifying effect of pressure oxidation on lignite tar oils (*cf. supra*) is compared with that due to alkali and acid washing. By oxidation with air at 35 atm. and 200° C. for 1½ hrs. the acid content of an oil was reduced from 10% to 3—4%, and a little additional washing sufficed to give a product similar in outward appearance to that obtained by Gluud (*cf.* J., 1920, 223 A) in the normal manner, but apparently still containing neutral oxygen compounds. The presence of lime favoured the purification process.—H. J. H.

Montan wax; Proportion of —— in low-temperature lignite tar and low-temperature tar paraffins. W. Schneider and O. Jantsch. Ges. Abhandl. Kennt. Kohle, 1919, 4, 363—372. Chem. Zentr., 1921, 92, II., 423.

The montan wax content of several low-temperature tar products derived from lignite was determined, using the insolubility of the wax in cold petroleum ether as compared with corresponding paraffins to effect a separation. The tar was first separated from free carbon by extraction with hot benzol, which was then evaporated off. 20 g. of the residue was extracted successively with 20 c.c., 10 c.c., and 10 c.c. of cold petroleum ether. The residue from a low-temperature tar from lignite was 3·8%, from Union briquettes 5·5%. The crude paraffin obtained by distillation in superheated steam of various lignite low-temperature tars was examined similarly. That from lignite yielded 10% of crude montan wax, that from Union briquettes 24%, and from the lignite tar 3%. The authors believe that during the steam distillation loss of montan wax occurs by decompositon.—H. J. H.

Hydrocarbons; Pressure oxidation of aromatic ——. H. Schrader. Ges. Abhandl. Kennt. Kohle, 1919, 4, 310—341. Chem. Zentr., 1921, 92, I., 537.

The auto-oxidation of aromatic hydrocarbons under high pressure by means of air in presence of aqueous alkali takes place at comparatively low temperatures (200° C.) so rapidly that in a few hours considerable quantities of oxidation products are formed. The oxidisability increases in the order, benzene, naphthalene, anthracene, and, with benzene homologues, with the number of aliphatic groups. Benzene and chlorobenzene first show signs of oxidation at 260° C.; at this temperature it is very considerable with naphthalene, phthalic acid being formed, whilst anthracene is distinctly oxidised at 210° C., anthraquinone being the chief product. With the benzene homologues the oxidation results in the conversion of some or all of the side chains into carboxyl groups. In addition to the above-named products all the hydrocarbons suffer degradation in varying extents to oxalic, formic, and acetic acids and carbon dioxide. Generally the presence of aldehydes could be established as intermediate products. The mechanism of these reactions, and the bearing of auto-oxidation on the processes occurring when aromatic hydrocarbons are used as fuel in an internal combustion engine, are discussed.—G. F. M.

Catalytic hydrogenation. Sabatier and Kubota. *See* XX.

Patents.

Mineral tars other than coal tar; Process of treating ——. W. Anderson and J. Meikle. E.P. 159,802, 31.10.19.

Mineral tars (other than coal tar), or mixtures of coal tar pitch with a mineral oil or tar oil, are treated with superheated steam as described for the treatment of coal tar (E.P. 158,337; J., 1921, 209 A). Crude Mexican petroleum tar on treatment between 450° and 500° C. yields bitumen, m.p. 180° C., an oil separable into a yellow resinous substance, a middle oil of sp. gr. 0·910, and a light oil of sp. gr. 0·880, and a gas. By employing a higher temperature, carbon and a resinous substance similar to that produced from coal tar are obtained.—L. A. C.

Pyridine bases; Manufacture of ——. Farbw. vorm. Meister, Lucius, und Brüning. E.P. 147,000, 6.7.20. Conv., 30.8.18. Addn. to 146,869 (J., 1921, 5 A).

A considerable improvement in the yield of pyridine bases and an acceleration of the reaction is realised by heating paraldehyde with aqueous ammonia in presence of an ammonium salt, such as the chloride or acetate. For example, 120 pts. of paraldehyde, 230 pts. of 5·5% aqueous ammonia, and 20 pts. of ammonium chloride, heated at 180° C. for 8 hrs., give a 70% yield of 2-methyl-5-ethyl-pyridine, b.p. 176° C.—G. F. M.

Phenols and "other aromatic hydrocarbons"; Process of removing —— from water or other liquids. R. M. Leggett, Assr. to Ozone Co. of America. U.S.P. 1,341,913, 1.6.20. Appl., 23.12.18.

The liquid containing phenol is treated with alum, or with ferrous sulphate and lime, and after settling and removal of the deposit is treated with ozone.—W. H. C.

Benzol; Production of rectified and pure products from crude ——. H. Heinemann and B. Hellmann. G.P. 329,962, 15.7.16.

The washed products are rectified in a double battery of distillation columns. Portions of the liquid are tapped off from points on the main columns for rectification within different narrow

limits in the secondary columns. Alternatively the pairs of columns—main and secondary—are coupled in series. Thus the liquid can be treated continuously, although the different pure products boiling within small limits are being simultaneously obtained.—H. J. H.

Tetrahydronaphthalene; Process for the preparation of ——. A.-G. für Anilinfabr. G.P. (A) 298,541, 2.8.16, (B) 298,553, 13.9.16, and (C) 301,275, 19.1.17.

A MIXTURE of naphthalene vapour and hydrogen is passed, without pressure, over a catalyst consisting of (A) nickel and copper oxides, (B) manganese oxide alone or mixed with nickel and copper oxides, or (C) an oxide of the rare earths, *e.g.*, thoria or ceria, either alone or mixed with one or more of the oxides claimed in (A) and (B).—A. R. P.

Paint or varnish. U.S.P. 1,370,195. *See* XIII.

Reduction of organic compounds. G.P. 330,812. *See* XX.

IV.—COLOURING MATTERS AND DYES.

PATENTS.

Cymene [azo] dyestuff and process of making same. Cymene [azo] dye. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,921–2, 2.9.19. Appl., 14 and 19.9.17.

(A) MONOAMINOCYMENE is diazotised and coupled in alkaline solution with an aromatic hydroxy-compound, *e.g.*, β-naphthol, which gives a bright orange-red dye. (B) Diazotised aminocymene is coupled in acid solution with an aromatic amine of the benzene or naphthalene series, or with an aminosulphonic acid. Cymene-azo-toluylenediamine is a yellow-brown dye.

DIMETHYL-DI-ISOPROPYLBENZIDINE (U.S.P. 1,314,924, *process of making same.* C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,925–6, 2.9.19. Appl., 19 and 15.9.17.

DIMETHYL-DI-ISOPROPYLBENZIDINE (U.S.P. 1,314,924, p. 323 A) is tetrazotised and coupled (A) with an aromatic amine or aminosulphonic acid, (B) with an aromatic hydroxy-compound or sulphonic acid thereof.

Sulphur dyes and process of making same. Green sulphur dye and process of making same. C. E. Andrews, Assr. to The Selden Co. U.S.P. 1,314,928–9, 2.9.19. Appl., 27.9.17 and 27.2.18.

(A) A MIXTURE of 5-aminocymene, *m*-toluylenediamine, and sulphur is heated at 200° C. for 5 hrs. and the melt treated with sodium sulphide and water. A yellow dye is obtained. The aminocymene may be replaced by other nitrogen compounds of cymene, and other aromatic nitrogen compounds may also be present. (B) A green sulphide dye is obtained by heating a mixture of acetaminocymene, a *p*-amino-hydroxy-aromatic compound, and sulphur to 200°—300° C.

Disazo dyes. W. M. Ralph, Assr. to National Aniline and Chemical Co., Inc. U.S.P. 1,371,979, 15.3.21. Appl., 24.4.20.

THE intermediate obtained by coupling 1-diazo-4-nitronaphthalene-6 (or 7)-monosulphonic acid with *m*-amino-*p*-cresol methyl ether is diazotised and coupled with 2.8.6-aminonaphtholsulphonic acid. The product dyes cotton, wool, silk, and other fibres blue shades which can be developed to give blue-black to green shades.—L. A. C.

Indigoid dyestuffs; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 298,098, 14.4.16.

HALOGENATED derivatives of isatin or naphthisatin capable of reacting in the α-position are condensed with 1-hydroxy-6-naphthol ethers, or derivatives of the same not substituted in the *o*-position to the α-hydroxyl group. The dyestuffs produced may be further halogenated. Dichloroisatin-α-chloride and dibromo-β-naphthisatin-α-chloride on condensation with 6-methoxy-1-naphthol yield products which dye respectively grey and olive-green shades; the former on halogenation gives a product which dyes black shades. 6-Methoxy-1-naphthol, b.p. 185° C. (12 mm.), is prepared by acetylation of 1-amino-6-naphthol, methylation of the hydroxyl group, hydrolysis of the acetyl group, diazotisation, and subsequent boiling.—L. A. C.

Disazo dyestuffs for wool; Manufacture of ——. Badische Anilin- und Soda-Fabr. G.P. 330,824, 6.4.19.

TETRAZOTISED 4.4′-diaminobenzophenone is combined with 1 mol. of β-naphthol and 1 mol. of naphtholdisulphonic acid, yielding dyestuffs whic dye wool in an acid bath scarlet shades fast to wash ing, milling, and light.—L. A. C.

N-Dihydro-1.2.1′.2′-anthraquinoneazine [Indanthrene]; Process for the preparation of chlorinated ——. Farbw. vorm. Meister, Lucius, un Brüning. G.P. 331,283, 28.11.16.

N-DIHYDRO-1.2.1′.2′-anthraquinoneazine is treate with sulphuryl chloride at 50°—100° C. in the pre sence of nitrobenzene.—A. R. P.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Microscope sections of cotton yarns and fabrics Rapid method for cutting ——. R. S. Willow and A. C. Alexander. J. Text. Inst., 1921, 1: 99—100.

SOLUTIONS of cellulose nitrate (this gives bette penetration and does not require protection fro moisture during drying) and acetate are suitabl for mounting sections of loose fibres, yarns, an fabrics. Two solutions of the acetate are used (*a*) a viscous syrup in acetone, and (*b*) 5—6 g. di solved in 100 c.c. of acetone. The fibres unde examination are immersed for 1 hr. in (*b*). A clea microscopic slide is painted with a layer of (*b* nearly dried, two or more layers of (*a*) are adde and on these the sample fibre is placed. More laye of (*a*) are then added, the slide is dried over calciu chloride so as to obtain a clear film, then hung i acetone vapour until the film becomes soft, and th is removed and embedded in paraffin wax of m.p 40°—45° C. In order to observe "Ball's growt rings," the section of a coarse cotton yarn is washe with xylol and absolute alcohol, and stuck to th slide with a smear of albumin (white of egg 25 c.c glycerin 25 c.c., and sodium salicylate 1 g.) withou heat. The slide is held in acetone vapour till th dope softens and is then immersed in acetone fo 2 hrs. to remove the dope, whereby each fibre stand freely on end on the slide. Caustic soda (45° Tw. (sp. gr. 1·225) is allowed to pass under th cover slip and the growth rings may then be ol served.—A. J. H.

Lignin and the sulphite [pulp] digestion proces W. Fuchs. Ber., 1921, 54, 484—490.

UP to the present it has only been shown definitel that the lignin substances are not homogeneous an that their complexity is probably analogous to th

of the proteins or carbohydrates of high molecular weight. Phenols are certainly present in them. They contain methoxy, hydroxy, acetyl, and carbonyl groups and also double bonds. Very little is known of the main portion of the lignin molecule and its structural relationships. The manufacture of sulphite pulp includes at least two separate processes, the detachment of the lignin substance from its natural form of combination in the wood and its subsequent conversion, possibly after further transformations, into soluble sulphur compounds. The nature of the former process is quite uncertain, since nothing is known definitely concerning the mode of union or admixture of cellulose and lignin. The second process may depend on the addition of sulphurous acid, at the double bond, to the carbonyl group or to the phenolic hydroxyl group; further, the possibility must be taken into account that the phenolic nuclei may behave in the sulphite process in their tautomeric form and therefore as unsaturated cyclic ketones.—H. W.

Oxy- and hydro-cellulose; Differentiation between —— by titration. C. G. Schwalbe and E. Becker. Ber., 1921, 54, 545—550.

Experiments were made with oxycelluloses prepared from cotton by the action of bleaching powder, permanganate, and hydrogen peroxide, respectively, and from purified cellulose ("cellulose for nitration") by the action of bleaching powder, and a hydrocellulose prepared by the action of 5% sulphuric acid. The air-dried material (1 g.) was mixed with water (about 50 c.c.) and titrated with $N/100$ sodium hydroxide solution. Litmus or phenolphthalein (at 80° C.) was used as indicator, the results being similar, but the end-point rather sharper with the latter. The titrations did not proceed very smoothly but were complete within a few hours (the acids are very sparingly soluble and only slowly neutralised). With bleaching powder oxycelluloses a very slight alkalinity was observed directly, due to the fact that the acids were largely present as their calcium salts; when the material was incinerated and the alkalinity of the ash added to the observed acidity, the expected values were obtained. It is thus shown that the "total acidity" of the oxycelluloses is very considerably higher than that of the hydrocelluloses or of the original materials. The presence of oxycellulose in overbleached cellulose was readily demonstrated in a similar manner. Hydro- and oxycelluloses may be readily distinguished qualitatively by mixing the preparations with distilled water and adding a drop of methyl orange. The liquid is coloured yellow in nearly all cases but is reddish orange with certain oxycelluloses. A few c.c. of concentrated sodium chloride solution is then added, which leaves the colour of the cellulose or hydrocellulose suspensions almost or entirely unchanged but gives a wine-red colour to the oxycellulose preparations. The method may be made quantitative by titrating back with $N/100$ sodium hydroxide solution; methyl red, however, should be used as indicator, since the end-point with methyl orange is indistinct.—H. W.

Newsprint [stock]; Recovering ——. C. Baskerville and R. Stevenson. J. Ind. Eng. Chem., 1921, 13, 213—214.

Treatment with alkali alone is insufficient to remove the ink from waste newspapers; but by addition of fuller's earth, which remains in suspension or in colloidal solution, the oil in the binding agent, and the carbon, are completely separated. The alkali and fuller's earth should be placed in the pulping machine, and heated to 50° C., before introducing the newspaper; the most suitable proportions are 60 lb. of sodium hydroxide, or preferably 200 lb. of soda ash, and 100 lb. of fuller's earth, per ton of paper. Pulping is complete in 1 hr.; after washing, the product may be bleached for 15 mins. with 20 lb. of sulphur dioxide per ton of newsprint stock.—W. J. W.

Book [paper] stock; Regenerating ——. C. Baskerville and C. M. Joyce. J. Ind. Eng. Chem., 1921, 13, 214—215.

Borax, 10 lb.; soap, 10 lb.; kerosene, 2 galls.; and pine oil, 2 galls., are added to 2000 lb. of bookstock, the mixture being pulped for 1 hr. at 75°—90° C. The treated pulp is washed and bleached. (*Cf.* U.S.P. 1,351,092; J., 1920, 386 A.)—W. J. W.

Patents.

Silk and other yarns; Treatment of —— to enable them to be worked up into fabrics. L. Mayfield. E.P. 159,907, 14.6.18.

Yarn which has had no previous dressing treatment whatever is wound on spools, bobbins, or pirns, and placed on shelves within a chamber the atmosphere of which is made humid by means of steam jets which impinge on the surface of water contained in a shallow tank secured to the bottom of the chamber. Yarn treated in this manner for at least 24 hrs. loses its harshness and may be easily worked up into fabrics on knitting machines.—A. J. H.

Fibres for spinning, e.g., typha fibres, which have deteriorated or have been produced in a porous or rough state; Improving ——. F. Dannert. G.P. 310,763, 16.6.18.

The fibres are soaked in a bath containing, *e.g.*, 0·2% of sodium-albumin, casein, or egg albumin in solution, and are subsequently treated with formaldehyde or a fixing salt.—L. A. C.

Fibres; Production of textile —— from wood, straw, or the like. R. Steimmig. G.P. 330,283, 12.8.17.

The wood or straw is arranged so that the fibres are parallel to one another, and the material binding the fibres together is dissolved by prolonged treatment under pressure with aqueous sodium sulphide solution, firstly just below 100° C., then at the boil, and finally at a lower temperature.—L. A. C.

Textile fibres; Production of —— from the fungus Phycomyces nitens. H. Conradi, A. Jentsch, P. Krais, and P. Nitsche. G.P. 330,579, 29.11.19.

The sporangium carriers (hyphæ) of the fungus are collected, and after suitable treatment are spun either alone or mixed with other fibres.—L. A. C.

Paper yarns and fabrics; Process for waterproofing ——. H. Th. Böhme A.-G. Chem. Fabr. G.P. 332,473, 12.4.17.

Paper goods are waterproofed with montan wax applied as a weak alkaline emulsion followed by a solution of a salt of a heavy metal. The viscosity and permanence of the wax emulsion may be increased, and the finish of the goods improved, by the addition of gelatin, starch, or agar-agar.
—B. V. S.

Cellulose boilers and the like; Process for charging ——. Zellstoff-fabrik Waldhof, and A. Schneider. E.P. 147,417, 7.7.20. Conv., 4.4.19.

Wood, straw, chips, etc., for use in cellulose boilers are first compressed into briquettes, with or without the use of binding substances (such as the concentrated waste liquors from cellulose boilers), whereby a great economy of space is effected.—A. J. H.

Cellulose; Process for obtaining —— from wood and similar material. E. Schmidt. G.P. 331,907, 18.12.19.

The material is treated with a solution of chlorine dioxide in water, carbon tetrachloride, chloroform, or other solvent, hot or cold, preferably under

pressure, and then boiled with caustic soda solution. The method is recommended for the further purification of cellulose obtained by other processes. —B. V. S.

Nitrocellulose and its compositions; Method for reducing the viscosity of solutions of ——. O. Carlsson and E. Thall. E.P. 136,141, 9.9.19. Conv., 6.12.18.

A SOLUTION of nitrocellulose in any of the usual solvents is heated in an autoclave (so as to avoid escape of solvent) at a temperature exceeding 60° C., but below the temperature at which decomposition takes place. Solutions capable of being easily filtered are obtained, and their viscosity is determined by the temperature and the duration of the heating.—A. J. H.

[*Cellulose acetate.*] *Plastic masses; Manufacture of* ——. H. Dreyfus. E.P. 160,225, 3.12.19.

IN order to obtain uniform plastic masses when cellulose acetate is kneaded with solvents of high boiling point (plastifiers) (*cf.* E.P. 132,283, 133.353, and 154,334; J., 1919, 896 A; 1920, 14 A; 1921, 42 A), the kneading is carried out in the presence of a quantity of a volatile liquid such as ethyl and methyl alcohols, benzene, etc., which has no solvent action on cellulose acetate, but which dilutes the plastifier so that it remains inactive until the volatile liquid is evaporated off.—A. J. H.

Cellulose-nitrate composition. Cellulose-ester composition. H. T. Clarke, Assr. to Eastman Kodak Co. U.S.P. (A) 1,370,878 and (B) 1,370,879, 8.3.21. Appl., 17.3.19.

THE compositions contain a simple dialkyl sulphone and (A) cellulose nitrate or (B) a cellulose ester. —L. A. C.

Cellulose articles; Process of treating regenerated ——. A. D. Conley and E. C. Stillwell, Assrs. to J. P. Hooper. U.S.P. 1,371,300, 15.3.21. Appl., 3.6.19.

REGENERATED cellulose articles are subjected to the action of "soluble castor oil," followed by treatment with an alkali hydroxide solution.—W. J. W.

Vulcanised fibre masses from cellulose; Production of ——. E. Schwabe. G.P. 324,281, 22.10.18.

CELLULOSIC materials, such as paper, cardboard, or textile fabric, are first coated with a porous filling material without the use of any adhesive and then hardened by treatment with a concentrated solution of a metallic salt, especially zinc chloride, followed by compression of the individual layers into a mass.—H. J. H.

Light, elastic material; Production of a —— *from chemically hardened cellulose.* Köln-Rottweil A.-G. G.P. 330,204, 14.6.19.

DISINTEGRATED cellulose material (vulcanised fibre) is worked to a plastic mass with regenerated cellulose or cellulose derivatives and/or other binders such as rubber or resin.—L. A. C.

Printers' ink; Removal of —— *from printed matter* [*paper*]. Newsprint Reclaiming Corp., Assees. of J. Jespersen. E.P. 138,628, 3.2.20. Conv., 1.7.18.

IN the preparation of pulp from printed paper, the removal of oils not saponifiable by alkalis and present in printers' ink is effected in a beater engine by means of a strainer, consisting of a perforated plate inclined at 45° to the horizontal. The perforations allow oil but no paper pulp to pass through the plate and collect before a barrier placed behind the plate. The oil is continuously withdrawn, and excessive frothing around the barrier is prevented by a spray of water.—A. J. H.

Paper-making machines. D. Russell. E.P. 14,660, 18.6.14.

IN a Fourdrinier paper-making machine a stream of hot or cold dry air is directed by means of a distributing pipe against one side of the felt, which at the time is not in contact with the supporting roller or the paper web, and is drawn through the felt by means of a suction pipe on the other side. Felts treated in this manner last longer and run cleaner, and the paper web tends to be flatter. —A. J. H.

Paper; Art of making water-resistant ——. W. Hoskins. U.S.P. 1,370,650, 8.3.21. Appl., 9.4.20.

A RELATIVELY small proportion of an insoluble fatty acid is thoroughly incorporated with the pulp. —A. R. P.

Paper; Process for sizing ——. F. Hassler. G.P. 331,549, 28.11.15.

THE condensation products obtained by treatment of aromatic hydrocarbons, or of mixtures of these with aromatic sulphonic acids, with formaldehyde, or by treatment of aromatic hydrocarbons with insufficient sulphuric acid for complete sulphonation, or of sulphones, are claimed for use in the tub-sizing of paper. These are added to the paper-pulp in the hollander alternately with the usual resin-precipitant, from ½% to 5% of the weight of the paper being used according to the degree of sizing required.—B. V. S.

Sizing paper pulp. Zellkoll Ges. E.P. 147,002, 6.7.20. Conv., 10.8.16.

SEE G.P. 303,828 of 1916; J., 1920, 264 A.

Drying machines [*for fabrics*]*; Doll-head bearings for steam cylinders of* ——. J. Ogden. E.P. 160,481, 15.10.19.

Washing wool and other fibrous or textile materials or fabrics; Machines for ——. T. W. Hawkins. E.P. 160,485, 21.10.19.

Paper, board, textiles, and felted or woven textile materials; Testing [*resistance to tearing*] *of* ——. S. D. Wells and R. J. Marx. E.P. 160,619, 21.1.20.

Drying varnished or other paper or like material; Apparatus for ——. F. Jenner. E.P. 160,718, 31.8.20.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Dyeing skins for furs. Desmurs. *See* XV.

PATENTS.

Dyeing and bleaching apparatus. A. Wioland. E.P. 146,945, 17.6.20. Conv., 7.7.19.

APPARATUS suitable for dyeing or bleaching fibres or yarns wound on bobbins of all shapes or on rollers comprises a reservoir for dye-liquor or bleaching solution and two dyeing or bleaching chambers each consisting of two compartments (open at the top for inspection) and containing a perforated hollow shaft upon which the material to be treated is wound. The liquor may be drawn through the material in either direction, and means are provided whereby air may be forced through the material after dyeing.—A. J. H.

Dyeing apparatus. F. B. Petrie and J. Boardman. E.P. 159,548, 29.10.19 and 30.6.20.

An apparatus suitable for dyeing fabrics and loose or spun fibres consists of a dyeing chamber and a reservoir for dye-liquor, connected by means of swivel members acting as valves, which are so controlled that the direction in which the dye liquor circulates through the dyeing chamber may be reversed, irrespective of whether the liquor is momentarily leaving or returning to the reservoir. —A. J. H.

Raw goods; Dyeing of ——. Chem. Fabr. Coswig-Anhalt G.m.b.H. G.P. 330,448, 29.10.14. Addn. to 288,687 (J., 1916, 357).

In dyeing goods on a tannin mordant the perborates or the like are added to the tannin mordant bath, and not to the dye-bath, as in the chief patent.—L. A. C.

Decomposition products of proteins; Process for the utilisation of —— [*in dyeing*]. C. Bennert. G.P. 331,234, 25.12.15. Addn. to 330,133 (J., 1921, 256 A).

Protalbinic or lysalbinic acids or the like, or the purified or unpurified salts of these acids, are used in dyeing animal fibres with vat dyestuffs. Good results are obtained without deterioration of the fibre. Decomposition products of casein, rice, or gluten may be added, for example, to weakly acid indigo vats.—A. R. P.

Printing textile fabrics [*cotton and silk*]. The Calico Printers' Assoc., Ltd., F. Ashton, and G. Nelson. E.P. 159,552, 28.11.19.

When a fabric printed as for battick styles with a wax resist is immersed in a solution of a metallic mordant and then dried, a large proportion of the mordant is fixed on the printed parts. The degree of fixation decreases irregularly towards the interior of the printed pattern. Novel effects are obtained by printing fabrics with a wax-resist, padding with a solution containing chromium, aluminium, iron, or copper salts, drying, removing the wax resist by means of alkaline solutions, and dyeing the fabric with a suitable mordant dyestuff. Before removing the wax resist, the fabric may be dyed with indigo, ice colours, or any dyestuff capable of being resisted with a wax resist. Veined or marbled effects may be obtained by the usual methods.—A. J. H.

Colouring design; Producing —— *on sheet material.* R. Sykora. U.S.P. 1,370,070, 1.3.21. Appl., 25.9.20.

Water and colouring matter are incorporated with a web of sheet material, and while it is still moist, a solution of a dehydrating agent is deposited upon its surface—A. J. H.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur dioxide and trioxide; Determination of —— *in burner-gases.* R. Dieckmann. Papierfabr., 1921, 19, 285—287.

A modification of Reich's method in which the iodine is replaced by $N/10$ alkali and both methyl orange and phenolphthalein are added as indicators. The two changes from red to yellow and from yellow to orange are very sharp. The volume of gas passed up to the first point corresponds to the percentage of SO_2+SO_3, the additional volume to effect the second change to that of SO_3 alone. The second titration in Sander's method (J., 1921, 256 A) after saturation with mercuric chloride gives a somewhat indistinct end-point, to which is attributed the fact that the method gives low SO_3 values. The author's method is convenient, speedy, and avoids the use of expensive reagents; it gives results accurate to about 2%.—C. I.

Nitric oxide, nitrogen peroxide, and aqueous solutions of nitric acid; Equilibrium between ——. C. L. Burdick and E. S. Freed. J. Amer. Chem. Soc., 1921, 43, 518—530.

In the absorption of nitrous gases, such as are formed by the oxidation of ammonia or in the arc process, the principal reactions taking place are $2NO+O_2=2NO_2$, and $3NO_2+H_2O=2HNO_3+NO$. The efficiency of absorption in the towers depends on the extent to which the latter reaction goes to completion, and this depends on temperature, concentration of nitric acid in the absorption liquid, and concentration of nitrogen peroxide in the original gas. The equilibrium conditions for this reaction have been determined experimentally for a wide range of conditions, and from the results a table has been constructed showing the percentage absorption of nitrogen peroxide at temperatures from 10° to 75° C., using as absorbing liquid nitric acid from 5% to 65% in strength and using original gases containing nitrogen peroxide varying from 0·1% to 20%. The favourable conditions for efficient absorption are low temperature, dilute nitric acid, and high concentration of nitrogen peroxide in the gas. Nitric acid above 50% in strength is a very poor absorber; in fact, if there is even a small proportion of nitric oxide in the gas, absorption will not occur at all until this has been oxidised by excess of oxygen. (*Cf.* J.C.S., May.) —E. H. R.

Phosphoric acid; Concentration of —— *by spray evaporation.* H. E. La Bour. Chem. and Met. Eng., 1921, 24, 466—468.

The difficulties incidental to the evaporation of phosphoric acid, owing to formation of scale from sludge and metaphosphate deposited on heated surfaces, are avoided by a spraying process in which the acid is heated without reaching its boiling point. The heating tank consists of two concentric compartments, the outer one being provided with a partition. Weak acid is introduced into the outer compartment near one side of this partition and flows round to an outlet near its other side, being heated in circulation by means of steam coils. The hot acid is delivered by a centrifugal pump to a spraying machine in which it is atomised and, in contact with air, is freed from water vapour and fluorine; no sludge is deposited in this machine as it is washed out by the acid, but if it is present in large quantities a settling trap may be introduced. The concentrated acid is returned to the inner compartment of the heating vessel. Through an overflow in this compartment a proportion of the finished acid is constantly discharged, but the bulk of it passes into the outer compartment through a communicating opening and is re-circulated, thus affording a supply of heat for evaporation, and ensuring the complete elimination of fluorine. —W. J. W.

Iron nitrides; Dissociation pressures of ——. A. A. Noyes and L. B. Smith. J. Amer. Chem. Soc., 1921, 43, 475—481.

The equilibrium constant of the reaction,

$$2Fe_xN+3H_2=2xFe+2NH_3,$$

was determined for different mixtures of iron and iron nitride by admitting hydrogen or ammonia into a tube at 460° C. containing iron and iron nitride, and, after allowing sufficient time for equilibrium to be established, withdrawing and analysing the gas. The value of the constant varied with the ratio Fe:N in the solid phase and

indicated the probable existence of a stable nitride Fe_8N, nitrides Fe_4N and Fe_4N, possibly metastable, and a stable nitride Fe_2N. The dissociation pressure of the iron nitride was calculated from K_1/K_2, where K_1 is the above equilibrium constant and K_2 is the constant for the reaction

$$N_2+3H_2=2NH_3.$$

The values found for the dissociation pressures were, for the first solid phase, 20,000, for the second, 102,000 to 590,000, and for the third, 41,000 atm. (*Cf.* J.C.S., May.)—E. H. R.

Ammoniacal liquor; Distillation of —— for the manufacture of liquor ammonia. W. Wyld. Chem. Age, 1921, **4**, 358—360.

An ammonia distillation system designed by the author embodies the following points. Carbon dioxide is removed from the liquor, preheated to 127° C., by spraying it through Körting sprays, at 25 lb. pressure, into an empty column without steam. The ammonia is all retained in solution. In place of a comparatively deep seal to the bubbling hoods, an arrangement of overflowing troughs and an adjustable serrated plate is used, so that the steam merely sweeps the surface of the liquor. In the heat exchanger for condensation of water from the ammonia gas, the inflowing crude liquor is maintained at a definite temperature (being previously heated by the exhausted liquor from the still) to avoid condensation of ammonia. Lime in the form of a thick cream is fed to the fixed ammonia still by gravity. This still is constructed of steel. The apparatus can be worked under a vacuum.—C. I.

Potassium chlorate; A new crystalline form of ——. E. R. Wolcott. J. Ind. Eng. Chem., 1921, **13**, 215—216.

Potassium chlorate is obtained in the form of long, fibrous crystals of silky appearance by treating a saturated solution with an aqueous solution of hydrocarbons prepared from Californian crude petroleum. Equal parts of the latter (20° B.; sp. gr. 1·16) and of oleum are mixed and agitated for 1 hr., without allowing the temperature to rise above the normal. The tar-like product which forms on standing is separated from the acid and dissolved in water to give a solution of sp. gr. 1·066. 10 c.c. of this solution is added to 200 g. of a saturated solution of potassium chlorate and the mixture is diluted to 800 c.c., boiled, filtered, and crystallised. Concentrated sulphuric acid or liquid sulphur dioxide may be used instead of oleum. Although in preliminary tests the crystals produced by the above method appeared to be less sensitive to friction than the ordinary variety, no essential difference was found with the frictional pendulum; but the crystals may lend themselves more readily to coating with a protecting film to reduce sensitiveness. (*Cf.* U.S.P. 1,355,203; J., 1921, 240 A.)—W. J. W.

Arsenious compounds; Volumetric determination of —— by means of potassium bichromate. R. Meurice. Ann. Chim. Analyt., 1921, **3**, 85—86.

The solution containing the arsenious compound (*e.g.*, sodium arsenite) is treated with 20 c.c. of 10% potassium bromide solution and its own volume of concentrated hydrochloric acid, and the mixture is titrated with standardised potassium bichromate solution. During the titration, a current of air is bubbled through the mixture and then through a mixture of starch paste and cadmium iodide solution. As soon as all the arsenious oxide has been oxidised, the addition of a further drop of bichromate solution liberates bromine, which is carried over into the iodide mixture, and a blue coloration is obtained.—W. P. S.

Silicic acid. V. Lenher. J. Amer. Chem. Soc., 1921, **43**, 391—396.

Very finely ground silica (pure sand ground to particles of about 0·004 mm. diam.) by the prolonged action of water forms a colloidal solution containing about 0·032 g. per l. When heated under pressure with excess of water at 300°—450° C. the same material forms a gel containing 15—18% of water. Attempts to obtain silicic acid or definite hydrates of silica by subjecting silica gels to enormous pressures were unsuccessful. All forms of silica, fused quartz, or quartz crystals, are converted into gels by prolonged treatment with water at temperatures of 300°—600° C. under pressure. It is concluded that the action of water on silica is that of a solvent, forming colloidal solutions or gels, and that the silicic acids are purely hypothetical. —E. H. R.

Mesothorium and radium; Isotopism of —— and separation of these elements from barium. R. K. Strong. J. Amer. Chem. Soc., 1921, **43**, 440—452.

Barium chloride containing mesothorium and radium was converted into hydroxide and the radioactive elements were concentrated by fraction crystallisation. The rich hydroxide was then converted into bromide and the radioactive elements further concentrated by recrystallisation of the bromide. The bromide method is much more efficient than the hydroxide method for the concentration. The ratio of mesothorium to radium was found to be unaffected by either fractionation process, and it is concluded that the two elements are true isotopes. (*Cf.* J.C.S., May.)—E. H. R.

Polythionic chlorides; Existence of —— in solution of sulphur in sulphur monochloride. G. Bru and M. Amadori. Atti R. Accad. Lincei, 191 **28**, I., 217—228.

Mixtures of sulphur and sulphur monochloride depress the freezing point of bromoform to an extent less than the sum of the depressions produced by sulphur and sulphur monochloride separately, and it is concluded that in the mixed solution polythionic chlorides are present in equilibrium with their components. The tetrathionic chloride, S_4Cl_2, is the highest member the presence of which in the bromoform solution is definitely indicated by the abnormal freezing point depression, but it is probable that chlorides richer in sulphur exist in solutions of sulphur in sulphur monochloride. The presence of polythionic chlorides explains the formation of polythio derivatives by the action of ordinary sulphur monochloride on organic substances and the formation of products containing sulphur in excess of the ratio S:Cl in the cold vulcanisation of rubber by means of sulphur monochloride.

Sodium amide; Preparation and properties of ——. J. M. McGee. J. Amer. Chem. Soc., 1921, **43**, 586—591.

Sodamide melts sharply at 208° C., and has no solvent action on glass below 240° C. when free from sodium hydroxide. At 270°—300° C. a slight action was noticeable after 2—3 days. Above 210° C. it decomposes under the catalytic influence of platinum into ammonia and either sodium imide or nitride. (*Cf.* J.C.S., May.)—J. K.

Boron; Preparation of —— by the dissociation of boron bromide. F. Meyer and R. Zappner. Ber., 1921, **54**, 550—560.

Under the influence of a high-tension arc boron bromide undergoes partial dissociation into boron and bromine, thus giving the most convenient method for preparing the former. Pure boron bromide is prepared by the action of the halogen on crude boron, and is subjected to the arc in the

gaseous form. The action of the arc on liquid boron bromide does not give satisfactory yields. Two forms of apparatus are described, both of which are constructed entirely of glass with ground-in joints. The first is suitable only for small quantities, and consists of a flask in which the bromide is boiled and which is attached to the discharge vessel, which is connected with a reflux condenser. In the second form the boron bromide is vaporised in a flask from which it passes over copper " wool " heated at 200° C. (to remove free bromine), thence through the vessel containing the electrodes, then to the condenser which returns the unattacked bromide to the flask. The boron obtained by this method is a very finely-divided, deep black powder which slowly becomes oxidised on exposure to air.—H. W.

Boron nitride; Preparation of considerable quantities of pure ——. F. Meyer and R. Zappner. Ber., 1921, **54**, 560—566.

The method consists in the thermal decomposition of the additive compound of ammonia and boron chloride into boron nitride and ammonium chloride. The apparatus consists of a silica tube wound with nichrome wire in three zones. It is fitted at one end with an arrangement for the introduction of regulated amounts of hydrogen, hydrogen charged with boron chloride vapour, and ammonia respectively, and is provided with a platinum pyrometer. The other end is adapted to a wider glass cylinder which serves for the collection of ammonium chloride and which can be heated electrically in such a manner that a uniform deposit of the salt is secured, thus avoiding the otherwise easy choking of the tubes. After the whole apparatus has been dried in a current of hydrogen at 300° C. the tube is heated at 500°—600° C., and regulated streams of ammonia and hydrogen charged with boron chloride are admitted, the former being always in large excess (this procedure ensures the production of a dense additive product). After complete admission of the reagents, the tube is heated in alternate zones for 5—6 hrs. at 500°—600° C. thus avoiding the mechanical removal of the boron nitride in the evolved gases), after which the temperature is gradually raised to 1000° C., whilst a slower current of ammonia passes over the product. As thus prepared (yield 80—85% calculated on the amount of boron chloride used) boron nitride is a colourless powder the density and stability towards water of which depend on the final temperature employed; at 800° C., and with a long period of experiment a very voluminous product is obtained which emits the odour of ammonia after exposure to the atmosphere for some time; more intensely ignited preparations are more stable towards moist air.—H. W.

Chlorine heptoxide; Preparation of ——. F. Meyer and H. G. Kessler. Ber., 1921, **54**, 566—571.

The preparation of chlorine heptoxide, in substance or dissolved in carbon tetrachloride, from potassium perchlorate and chlorosulphonic acid is described, but the complete elimination of impurities containing sulphur (not exceeding 2% in amount) appears impossible. Pure chlorine heptoxide can be prepared from phosphoric anhydride and perchloric acid (70%), the former being added very cautiously to the latter or, preferably, the components being previously absorbed by or mixed with ignited kieselguhr or " K-silicic acid " (Elektro-Osmose A.-G). The yields are poor, but the latter method is very suitable when a small quantity of the pure material is required. Pure solutions of chlorine heptoxide in carbon tetrachloride are obtained by cautiously adding perchloric acid (70%) to a suspension of a large quantity of phosphoric oxide in carbon tetrachloride, which is violently agitated and maintained at 0° C.; the product is warmed and filtered, yielding a solution containing about 2·5% of heptoxide, which can be raised to 7—8% by distilling the solvent as far as possible at 0° C. in a water pump vacuum, digesting the residue for some time at 70°—75° C., and subsequent distillation in a vacuum till a temperature of 80° C. is recorded; small amounts of chlorine and chlorine peroxide were removed by warming the distillate at 80° C. If more concentrated solutions are required, the whole process is repeated, using the 7—8% solution as starting material; three successive treatments give a product containing 20—25% Cl_2O_7. (*Cf.* J.C.S., May.) —H. W.

Arsenate and arsenite. Sears. *See* XXIII.

Nitrous fumes in air. Moir. *See* XXIII.

Patents.

Nitric acid; Method of producing ——. Y. Kawakita. U.S.P. 1,371,789, 15.3.21. Appl., 2.4.18.

By means of a jet of compressed air, a jet of water is drawn into, and atomised in, a chamber containing water. Intermittently, an electric current is passed through the water jet, and electric sparks are passed between it and the water in the chamber, by which the air becomes rapidly heated and nitrogen oxides are formed; the heat generated by the sparks further serves to evaporate the atomised water, and the resulting fall in temperature cools the generated gas, with formation of nitric acid. —W. J. W.

Nitric acid; Production of concentrated ——. Badische Anilin- und Soda-Fabr. G.P. 302,411, 24.7.17.

A mixture of dilute nitric acid and concentrated sulphuric acid passes down two separate columns in which it is treated with a counter-current of steam. Concentrated nitric acid is delivered from the first column, and a portion of the vapour issuing from the second column, in which the last traces of nitric acid are removed from the mixture, is employed in the first column instead of fresh steam. —L. A. C.

Nitric acid; Encased column apparatus especially for use in the manufacture of ——. W. Strzoda. G.P. 330,019, 13.10.17. Addn. to 272,158.

The apparatus, constructed from brittle material cemented and strengthened as described in the chief patent (*cf.* E.P. 26,732 of 1913; J., 1914, 643), is arranged to provide the maximum reaction surface and area of the gas channels in proportion to the diameter of the tubes. The gas channels, which are of circular cross-section, are arranged around a central overflow tube, and are covered with annular hoods fitted with overflow dishes. —L. A. C.

Oxides of nitrogen; Process and apparatus for obtaining —— *from atmospheric air.* F. I. du Pont. U.S.P. 1,370,295, 1.3.21. Appl., 15.7.19.

The apparatus includes a tubular reaction chamber with a central enlarged portion, a cylinder surrounding the parts near this enlargement, and electrodes in the two ends of the tubular chamber. —C. I.

Oxides of nitrogen; Process of making ——. A. H. White. U.S.P. 1,370,867, 8.3.21. Appl., 19.6.19.

An alkaline-earth cyanamide is hydrolysed, and the ammonia liberated is conducted into an absorbent till no more phosphine is generated from the cyanamide; the ammonia, free from phosphine, is then mixed with air and passed over a catalyst. —W. J. W.

Oxides of nitrogen; Preparation of —— by the catalytic oxidation of ammonia. Badische Anilin- u. Soda-Fabr. G.P. (A) 303,331, 10.12.14, and (B) 307,001, 6.2.16.

BASE metals or their oxides or mixtures or compounds are used as catalysts, and the gas mixture preheated to over 400° C. is allowed to come into contact only with (A) silica or glazed ware high in silica, or (B) oxides or carbonates of calcium, magnesium, or aluminium or a mixture thereof in massive form, before reaching the catalyst.—C. I.

Nitrous gases; Manufacture of —— from the air or other oxygen-nitrogen mixtures by means of the electric arc. O. Lummer, and Rütgerswerke A.-G. G.P. 331,040, 20.9.18.

THE nitric oxide formed under high pressure in the reaction vessel is cooled *in situ* at a constant rate until it attains a temperature below which it does not dissociate under atmospheric pressure, *i.e.*, 130° C., when it is led into vessels for subsequent treatment.—L. A. C.

Nitrogen; Regenerative furnace for the combustion of ——. Gewerkschaft des Steinkohlenbergwerks Lothringen, and M. Kelting. G.P. 331,488, 31.12.19.

Two rows of narrow jets are arranged on the circumference of a cylindrical reaction chamber, and are connected with a pipe conveying fuel. The jets, which are graded as regards diameter, enter the walls of the chamber at an acute angle, and are provided with several openings arranged in one plane in the form of a fan. The fuel may be gaseous, liquid (as a spray), or solid (as powder). The pointed flames effect a quick mixing of the gases in the reaction chamber.—C. I.

Nitrogen oxides; Process for the preparation of ——. "Azot" Ges.m.b.H. G.P. 331,591, 27.10.18.

HIGHLY-HEATED nitric oxide or a mixture thereof with air is allowed to expand in a chamber maintained at 150°—300° C., and air or oxygen is admitted. The nitrogen of the air is oxidised along with the nitric oxide. The reaction may be accelerated by a platinum catalyst.—C. I.

Aluminium nitrate, sulphate, or chloride; Process for the removal of iron from solutions of ——. B. E. D. Kilburn. From Det Norske Aktieselskab for Elektrokem. Ind. Norsk Ind. Hypotekbank. E.P. 139,470, 19.2.20.

IN order to precipitate iron in a readily filterable form 2—10% of the equivalent in calcium carbonate of the aluminium present is added to the solution and a quantity of ferric oxide. The iron is then precipitated with an alkali. The ferric oxide may be washed and used again.—C. I.

Sea water; Concentration of —— [for salt manufacture]. T. A. Reid. E.P. 159,592, 28.11.19.

AN apparatus with which salt can be profitably manufactured from sea water in temperate climates comprises a salt pan in three parts, and either provided with its own fireplace or heated by flue gases from a boiler. In the front part sea water is warmed to at least 26° C., and it then passes to the back part, which is fitted with a series of wooden towers down which the warm sea water flows until concentrated to a sp. gr. of 1·2. It then passes to the central pan, in which the deposition of salt takes place. If a boiler is in use, it may be fed with sea water, which passes on to the evaporating pan when concentrated, and the exhaust steam used for heating another pan.—C. I.

Catalytic iron [for ammonia synthesis]; Manufacture of —— or catalysts containing catalytic iron. The Nitro-Fixation Synd., Ltd., and H. C. Jenkins. E.P. 159,960, 5.12.19.

A SOLUTION of commercially pure ferric nitrate is freed from phosphorus and arsenic, then from chloride by addition of its equivalent of silver nitrate, and is then evaporated and the residue heated. Before nitrous fumes cease to be given off the heating is stopped and the mass lixiviated and washed. The washings carry away, along with part of the nitrate, the sulphur impurities. The mass is then ignited and reduced by hydrogen or preferably ammonia. If desired, pumice or asbestos freed from impurities may be added to the chloride-free solution. Such promoters as ammonium molybdate, potassium osmate, titanium or uranium nitrate, or an alkali tungstate may be added to the ferric oxide before reduction.—C. I.

Ammonia synthesis catalyst, and method of making same. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,352,177, 7.9.20. Appl., 25.6.18.

A NUMBER of processes for producing porous cyanamide catalysts at comparatively low temperatures are described. For example, calcium cyanide is obtained by passing hydrogen cyanide into a solution of calcium in liquefied ammonia, and calcium cyanamide by adding calcium to a solution of cyanamide in liquefied ammonia.

Chemical syntheses [ammonia formation]; Apparatus for effecting exothermic —— at high temperature and pressure. G. Claude, Assr. to Soc. l'Air Liquide, Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude. U.S.P. 1,371,299, 15.3.21. Appl., 2.2.20.

THE apparatus comprises an outer resisting wall separated by a heat-insulating medium from an inner wall forming a reaction chamber, and having gas outlets. Through this chamber passes an axial tube through which the reacting gases are introduced. Projections on this tube act as supports for catalytic material, and means are provided for delivering an electric current to the tube whereby it can serve as a heating element for the reaction. —W. J. W.

Nitrogenous compounds; Process of and means for forming ——. J. C. Clancy, Assr. to The Nitrogen Corp. U.S.P. 1,352,176, 7.9.20. Appl., 1.9.17.

BARIUM cyanide is heated in presence of nitrogen at 400°—500° C. to produce a porous cyanamide especially suitable for use as a catalyst, *e.g.*, in the preparation of hydrocyanic acid from a mixture of hydrogen, nitrogen, and methane or acetylene.

Carbon bisulphide; Method of making ——. K. P. McElroy. U.S.P. 1,369,825, 1.3.21. Appl., 27.5.19.

FUEL and sulphur are charged into a shaft similar to a gas-producer with an air inlet at the base, and the gases generated are scrubbed with oil to recover carbon bisulphide.—C. I.

Borax; Process of recovering —— from saline waters. G. B. Burnham. U.S.P. 1,370,278, 1.3.21. Appl., 30.6.19.

THE borax is separated from chlorides, sulphates, and carbonates of sodium and potassium by fractional crystallisation.—C. I.

Alkali sulphates, alkaline-earth oxides, and hydrochloric acid; Manufacture of ——. Salzwerk Heilbronn A.-G., G. Kassel, and T. Lichtenberger. G.P. 302,496, 9.6.16. Addn. to 299,775 (J., 1920, 749 A).

MIXTURES of naturally-occurring salts of alkalis and alkaline-earths, or of magnesium, containing

chlorides with or without sulphates, *e.g.*, mixtures of carnallite with kainite, or with polyhalite, are melted and treated with steam.—W. J. W.

Alumina; Treatment of clays for production of ——. P. Askenasy and V. Gerber. G.P. 306,355, 28.3.17.

ALUMINA is obtained from clays and similar materials by heating them at a moderate temperature with barium compounds and lime, in presence of a fluxing agent, such as sodium chloride. The barium aluminate solution is then treated with alkali carbonates or sulphates, and the precipitated barium compounds may be re-utilised in the process.—W. J. W.

Alumina; Preparation of —— from silicious clays. Aktieselskabet Höyangfaldene Norsk Aluminium Co. G.P. 332,389, 5.7.19.

THE clay is heated with calcium carbonate and a quantity of an alkali compound insufficient to convert the aluminium content of the clay into alkali aluminate, and the product is washed with sodium carbonate solution in two stages.—C. I.

Sulphur dioxide; Production of —— from calcium sulphate. Chem. Fabr. vorm. Weiler-ter Meer. G.P. 307,772, 20.10.17.

A MIXTURE of calcium sulphate and calcium sulphide is heated above 1000° C., whereby sulphur dioxide is formed in accordance with the equation: $3CaSO_4+CaS=4CaO+4SO_2$.—L. A. C.

Bleaching powder; Apparatus for manufacture of ——. A. Pfülf. G.P. 329,844, 25.7.19.

To promote the interaction between lime and chlorine, the former is introduced into a shaft-shaped chamber in which are a number of devices, consisting of hollow or solid cylinders, prisms, or rods of star-shaped cross-section, which are mounted on parallel axes and can be rotated. Slot-shaped openings are formed between these devices, through which the material is caused to pass from one side of the chamber to the other.—W. J. W.

Alkali hypochlorites; Preparation of stable solid solutions of ——. R. Mandelbaum. G.P. 330,192, 11.1.19.

NON-CRYSTALLINE solid solutions of alkali hypochlorites are obtained by mixing them with colloids, or mixtures of these with water-absorptive agents. Thus, sodium silicate solution (38° B.; sp. gr. 1·357), 500 pts., is evaporated to about two-thirds of its volume, and the cooled semi-solid solution is added to 10 pts. of sodium hypochlorite solution (35° B.; sp. gr. 1·320), with or without addition of calcined sodium carbonate.—W. J. W.

Perborates; Manufacture of —— with maximum oxygen content. Aschkenasi. G.P. 329,845, 27.11.19.

IN the manufacture of perborates by any suitable method, the oxidation is not carried beyond a stage corresponding to 23% of active oxygen. In perborates containing 28·4% of available oxygen, the amount is reduced to 21·5% within a year.
—W. J. W.

Crude calcium cyanamide; Manufacture of —— in a rotary furnace. G. Polysius. G.P. 329,961, 18.10.19.

ADHERENCE of material to the walls of the rotary furnace is overcome by cooling the walls, *e.g.*, with water. The most effective procedure is to cause the cooling material to strike the walls obliquely at that part where the material is banked up.
—W. J. W.

Primary alkali phosphates; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 330,342 and 330,343, 11.9.17.

DISODIUM phosphate is decomposed with hydrochloric acid, the solution is concentrated and separated from the alkali chloride, heated to expel hydrogen chloride, and a secondary phosphate then added to combine with the free phosphoric acid. The mixture of 96% of dihydrogen-sodium phosphate and 4% of sodium chloride obtained may be used for enriching animal fodder.—W. J. W.

Chlorates, bromates, and iodates; Preparation of ——. H. Schulz. G.P. 330,941, 11.3.19. Addn. to 328,211 (J., 1921, 147 A).

CHLORINE, bromine, iodine, or their hydrogen compounds mixed with air are introduced with or without pressure into water containing a suspended or dissolved salt and a catalyst. By leading hydrochloric acid and air into a suspension of calcium carbonate and manganese dioxide, over 95% of the chlorine is obtained as calcium chlorate.—C. I.

Copper sulphate; Manufacture of —— from residues containing copper. A. Friedlaender. G.P. 331,144, 5.9.18.

THE residues are dissolved in a solution made strongly acid with sulphuric acid in an electrolytic cell, without a diaphragm, in which the residues act as anode. The copper sludge deposited on the cathode is mixed to a paste with the acid from the cell, or with fresh acid, and is treated with hot air and steam.—L. A. C.

Mechanical sulphate kilns; Apparatus for feeding sulphuric acid to ——. Farbenfabr. vorm. F. Bayer und Co. G.P. 331,238, 31.7.19.

THE acid is introduced through a small vessel attached to the spindle of the agitator and revolving with it.—C. I.

Sodium sulphate; Preparation of anhydrous ——. A. Hoffmann. G.P. 331,489, 17.5.18.

GLAUBER'S salt or its solution, pure or mixed with other salts, is treated with volatile substances readily soluble in or miscible with water, or with their vapours, at a temperature above the transition point between the hydrated crystallised salt and the anhydrous salt.—C. I.

Potash manufacture; Process for treating residual liquors from ——. R. Mewes. G.P. 331,886, 8.7.15. Addn. to 305,082 (J., 1920, 404 A).

THE liquor is treated with crude calcium cyanamide. The nitrogen of the latter is converted into ammonia, or ammonium sulphate or chloride, and the metals precipitated as oxide, carbonate, or sulphate.—C. I.

Potassium nitrate; Process for the production of —— from crude calcium cyanamide. E. Hene and A. van Haaren. G.P. 332,002, 14.4.20.

CRUDE calcium cyanamide, potassium sulphate, nitric acid, and water are stirred together at a temperature below 100° C., preferably 25°—35° C., and the liquor filtered.—C. I.

Causticisation of soda in the cold; Process for the ——. Schweizerische Sodafabr. G.P. 332,003, 5.6.19.

A MIXTURE of soda solution and lime is treated in a revolving mixer similar to a centrifugal machine, when interaction is speedy and complete without heating, 10 cub. m. of liquor being causticised in 10 mins.—C. I.

Magnesium chloride liquors; Treatment of ——. W. Esch. G.P. 332,153, 12.6.19.

PART of the magnesium, after addition of magnesium oxide or hydroxide, is obtained as basic carbonate by treatment with ammonium carbonate below 50° C. The remainder is obtained as hydroxide, with recovery of the ammonia or carbon dioxide and ammonia, the liquor being first freed from sulphate by addition of calcium chloride solution.—C. I.

Colloidal metallic oxides; Process for the electrical preparation of ——. A. Wander A.-G. G.P. 332,200, 4.9.19.

A MAIN circuit with direct or alternating current passes through an electrode of the metal the oxide of which is required, placed in a medium for dispersion, to which a protective colloid may be added. The metal is oxidised electrolytically, and the layer of oxide is dispersed by the discharge of a condenser placed in a circuit parallel to the main circuit. Oxides of copper, nickel, and iron and oxides and hydroxides of lead, zinc, and cadmium are mentioned.—C. I.

Oxygen and nitrogen; Processes for separating —— and apparatus therefor. M. Zack. E.P. 152,643, 3.9.20. Conv., 15.10.19.

A COOLED gaseous mixture of oxygen and nitrogen at a certain pressure is introduced into a turbo-engine actuated by an electric motor, and there undergoes further cooling through expansion. By the action of electro-magnets attached to a rotating hollow ring, cooled by liquid air, oxygen, being paramagnetic, is drawn from the turbo-engine at its periphery into the ring, while the nitrogen passes through an outlet parallel to the shaft of the turbo-engine into a centripetal turbine, operated by a second electric motor at a different speed from the first, and thence to an outlet. The gaseous mixture freed from part of the nitrogen passes into a second cooled hollow ring, which is also provided with electro-magnets and is rotated by the second electric motor. Periodically the current to the electro-magnets of the first ring is interrupted, and the oxygen passed into the second ring, from which both gaseous and liquid oxygen can be drawn off through two outlets.—W. J. W.

Nitrogen; Production of —— [from producer gas] suitable for the catalytic manufacture of ammonia. Badische Anilin- und Soda-Fabr. G.P. 306,302, 3.7.15.

PRODUCER gas is burnt with a small excess of oxygen or air, pure hydrogen is added to combine with the excess of oxygen, and carbon dioxide and other impurities are subsequently removed from the gas.—L. A. C.

Hydrogen manufacture by iron contact process; Utilisation of heat retained by generated hydrogen and excess steam in ——. F. Lang. G.P. 330,800, 7.11.16.

BY means of a system of heat exchangers the waste heat from the hydrogen and steam may be utilised for generating further steam, for preheating the boiler feed water, and for removing air from the cooling water.—W. J. W.

Hydrogen production by the iron contact process; Process and apparatus for utilisation of the waste heat available in ——. F. Lang. G.P. 332,111, 8.11.16. Addn. to 330,800 (*cf. supra*).

THE heat of the hydrogen and water vapour leaving the converter and also the heat of the gases leaving it during the reduction, washing, heating, and air blast periods are used for generating the steam required for the process or for the heating of boiler feed water. The apparatus consists of a heat exchanger with suitable inlet connexions and an exhaust for the waste gases or a two-chambered exchanger heated on one side by the hydrogen and on the other by the waste gases.—C. I.

Sulphur dioxide; Oxidation of —— and catalyst therefor. F. Slama and H. Wolf, Assrs. to General Chemical Co. U.S.P. 1,371,004, 8.3.21. Appl., 9.10.14.

SEE E.P. 23,541 of 1913; J., 1915, 833. It is specified that the catalyst be distributed on a very finely divided carrier, not exceeding 60 microns in diameter.

Aluminium nitride; Manufacture of ——. V. Gerber. E.P. 139,195, 18.2.20. Conv., 18.2.19.

SEE U.S.P. 1,350,149 of 1920; J., 1920, 657 A.

Cyanamides; Process for the production of ——. L. E. Friderich, Assr. to Soc. F. Gros et Bouchardy. U.S.P. 1,371,616, 15.3.21. Appl., 17.10.18.

SEE E.P. 132,622 of 1918; J., 1919, 818 A.

Tin oxide and zinc oxide; Production of ——. D. de Ros. U.S.P. 1,372,407, 22.3.21. Appl., 30.10.19.

SEE E.P. 142,157 of 1918; J., 1920, 448 A.

Nitrogen of the atmosphere; Fixation of the ——. R. Pearson. U.S.P. 1,372,541, 22.3.21. Appl. 13.2.19.

Tin salts. E.P. 159,659. *See* X.

Calcining magnesia. E.P. 160,231. *See* XI.

VIII.—GLASS; CERAMICS.

Kaolins and clays; Shrinkage of —— on drying. A. Bigot. Comptes rend., 1921, 172, 755—758.

A COMPARISON of certain kaolins and clays and an argillaceous sand from different sources shows that the free silica contained in the clays renders the material less plastic. The plasticity is obtained by dividing the colloidal water (water of plasticity, water adsorbed by the colloids present) by the total water absorbed and multiplying this quotient by the shrinkage on drying. Elevation of temperature or of pressure diminishes both the colloidal and the interposed water (water filling the spaces between the particles), but the diminution of the latter is very slight as compared with that of the former.—W. G.

Kaolins, clays, and bauxites; Variation of volume of —— under the influence of heat. A. Bigot. Comptes rend., 1921, 172, 854—857. (*Cf. supra.*)

SAMPLES of kaolins, clays, and bauxites were powdered, sieved, mixed with water, and compressed in moulds. The lengths of the samples were measured from 0° C. at each successive 100° up to the temperature at which they showed signs of fusion. The results are shown graphically and indicate that bauxites, kaolins, and clays, which do not contain any free silica, commence to contract below 1000° C. Any clay or bauxite which expands below 1000° C. contains free silica. Clays and kaolins when heated rapidly puff up before reaching their melting-point, but bauxites do not show this puffing. The swelling or puffing up is due to the volatilisation of silica or silicates.—W. G.

Heat losses of metallurgical furnaces. Rosin. *See* X.

Patents.

Glass melting furnaces; Gas-fired ——. S. G. Curd. E.P. 159,559, 20.11.19.

Two gas producers are used and are operated alternately, the gas being produced by passing a mixture of superheated steam (preferably at 800° F. and 10 atm. pressure) and hot air through burning fuel. The gas and hot air are admitted simultaneously to the melting tank, the flow of gas through the furnace being periodically reversed in direction. The steam is generated and superheated by the waste gases, which also preheat the air. The gas is slightly superheated before use.—H. S. H.

Lehrs or kilns; Annealing —— for glass and other articles. S. and J. E. Laycock. E.P. 160,282, 19.12.19.

An annealing lehr having an internal endless chain conveyor for carrying the material has the gas ports constructed to pass the heating gases into direct contact with the material being treated in the annealing chamber. A regenerative chamber for the gas is placed directly under the furnace part of the lehr, so that the gas is preheated before it enters the lehr and a better pressure of gas is maintained. Waste hot air from round and about the melting furnace is collected and mixed with the gas before it enters the lehr.—H. S. H.

Glass composition and articles made therefrom. E. C. Sullivan and W. C. Taylor, Assrs. to The Corning Glass Works. U.S.P. 1,369,988, 1.3.21. Appl., 3.5.19.

A glass contains silica, soda, and two divalent oxides in the molecular proportions of 100 of silica to at least 20 of alkali and at least 6 of divalent oxides.—H. S. H.

Glass; Method of and apparatus for removing striæ from melted ——. S. R. Scholes, L. W. Nicols, and W. F. Kaufman. U.S.P. 1,370,673, 8.3.21. Appl., 8.10.19.

The formation of striæ in molten glass is prevented by agitating the pot and its molten contents at a uniform temperature until complete mixing of the constituents takes place. This is accomplished by providing means for moving the pot and its contents around an axis inclined to the horizontal. —H. S. H.

Refractory and [electrical] insulating product and process for the manufacture of same. G. L. Dimitri and J. E. Delaunay. E.P. 142,512, 1.5.20. Conv., 21.11.16.

A natural silicate of magnesium and a flux consisting of one or more natural or artificial multiple silicates (*e.g.*, felspar) are mixed in the powdered state, moulded or compressed, and after complete desiccation cut or fashioned into the required form and baked at about 1450° C.—H. S. H.

Refractory articles made from china clay and method of manufacture. The Osmosis Co., Ltd., D. Northall-Laurie, and W. R. Ormandy. E.P. 159,737, 22.1.20.

The clay is brought into the sol condition by the addition of a suitable electrolyte, the coarser particles are allowed to settle, and the fine clay particles are separated from the suspension by electro-osmosis or by precipitating the sol suspension by means of a solution of aluminium sulphate or other coagulant. A slip is made from the purified clay and the articles are cast from it. The treated clay will sinter at a temperature between 1400° and 1500° C., and the use of felspar is thus avoided. Grog consisting of vitrified china clay may be added to reduce the firing shrinkage. Articles made in this way are more refractory than those prepared from kaolin and felspar and resist temperature changes more effectively than porcelain prepared by any known process.—H. S. H.

Oven or kiln; Gas-fired —— for use in the manufacture of tiles, pottery, and other ware or other purposes. J. H. Marlow. E.P. 159,522, 23.7.19.

Three heat-distributing conduits extend throughout the length of the oven, and between the central conduit and each of the side conduits wheeled carriers travel. Each conduit communicates with a combustion chamber placed under it and is perforated so as to allow heat and gases to pass into the interior of the oven. The air is heated before entering the combustion chamber.—H. S. H.

China clay and other plastic materials; Drying of ——. C. J. Grace. E.P. 159,525, 23.8.19 and 25.2.20.

The china clay sludge is pumped into a tubular filter which is connected with a heated tubular drying chamber. The cake of clay is moved from the filter to the drying chamber either intermittently by means of a ram or continuously by conveyor vanes.—H. S. H.

Glass; Method and apparatus for the manufacture of ——. A. Ferguson, Assr. to F. W. Passmore. U.S.P. 1,371,084, 8.3.21. Appl., 7.9.20.

See E.P. 154,251 of 1919; J., 1921, 46 A.

Firing porcelain. G.P. 331,924. *See* X.

IX.—BUILDING MATERIALS.

Patents.

Cement materials, magnesite, and the like; Method for burning or calcining —— and apparatus therefor. A. Hauenschild. E.P. 159,780, 28.4.20.

The charge is inserted with the fuel in the form of a continuous vertical column, the mineral being in direct contact with the fuel on all sides and the usual vertical alternations of fuel and mineral being absent. An annular fuel shoot extends downwards some distance into the kiln shaft and prevents the fuel from mixing with the mineral. Air under pressure enters by blast nozzles at the sides of the kiln shaft. A cover on the shoot prevents the hot gases from escaping without permeating the mineral.—H. S. H.

Gypsum products; Process of ageing calcined —— and product thereof. H. E. Brookby, Assr. to United States Gypsum Co. U.S.P. 1,370,581, 8.3.21. Appl., 8.3.20.

A calcined gypsum product comprises a dry powder of unset commercial plaster of Paris with a small amount of water-soluble deliquescent substance intimately incorporated.—H. S. H.

Plastic composition and process for making the same. R. G. Erwin, Assr. to International Bitu-concrete Co. U.S.P. 1,370,637, 8.3.21. Appl., 6.7.20.

A plastic composition is produced by suspending a mixture of mineral dust (all of which will pass a 200-mesh sieve, 60% being smaller than 0·02 mm.), sodium chloride, and sodium sulphate in preheated bitumen, and adding pulverised sulphur to the mass. The whole is agitated in a vat subjected to suction and heated sufficiently to combine the ingredients and their derivatives. The composition is then mixed with comminuted vegetable particles of various sizes in sufficient quantity to fill the pores within and the voids between the vegetable particles and to coat and bind them together, and the mass is agitated in a vat under the influence of

sustained heat and suction. After removing the composition from the vat it is compacted to shape. —H. S. H.

Keene's cement; Manufacture of ——. W. Hoskins, Assr. to The Best Bros.' Keene's Cement Co. U.S.P. 1,370,968, 8.3.21. Appl., 13.5.18.

Gypsum is ground very fine and passed continuously at a uniform rate through a rotary, internally-fired kiln, after which it is mixed with sufficient lime to neutralise all acidity.—A. R. P.

Heat-insulating material and method of making same. C. H. Bennett, J. F. Palmer, and F. V. Wedlock, Assrs. to Bentex Co. U.S.P. 1,371,016, 8.3.21. Appl., 18.6.20.

A rigid, cellular, heat-insulating material is made from a "dough" having the following percentage composition by weight:—Asphaltum, 27·0; infusorial earth, 11·0; magnesium carbonate, 5·0; crude rubber, 26·9; sulphur, 14·9; sulphur-treated corn (maize) oil, 2·6; petroleum tailings, 5·8; sodium bicarbonate, 6·0; alum, 0·8. The mixture is heated under pressure to a sufficient temperature and for a sufficient time for vulcanisation. The material is rolled while still hot and finally cooled. It maintains its rigidity at the ordinary temperatures of artificial refrigeration.—H. S. H.

Mortar-forming material. F. Hartner. U.S.P. 1,371,762, 15.3.21. Appl., 1.8.19.

See G.P. 312,239 of 1917; J., 1919, 905 A.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Iron, carbon, and oxygen; Chemical equilibrium between ——. A. Matsubara. Trans. Amer. Inst. Min. and Met. Eng., Feb., 1921. 52 pages.

Equilibrium compositions of the gaseous phase in the system, CO-CO_2-Fe, were measured at 863° C., 1070° C., and 1175° C. The systems, CO-CO_2-FeO (Fe) and CO-CO_2-Fe_3O_4 (FeO), were studied at several temperatures higher than 700° C., also systems containing iron carbide. At a temperature of about 1200° C., under a pressure of 1 atm., the dissociation pressure of the carboniferous iron phase is equal to that of carbon monoxide, and neither carburisation nor decarburisation occurs even in a current of pure carbon monoxide. Lower temperature or higher pressure values increase the relative pressure of carbon monoxide in the gaseous phase. From the data obtained the existence of oxygen-bearing iron is inferred, and the equilibrium conditions are discussed with relation to case hardening, malleable casting, and blast furnace conditions. —C. A. K.

Iron; Influence of copper on the rate of solution of —— *in acids.* F. K. Bell and W. A. Patrick. J. Amer. Chem. Soc., 1921, 43, 452—465.

Experiments with pure iron-copper alloys containing from 0·1% to 5·0% Cu showed that the copper had a marked retarding effect on the rate of solution of the iron in 28·7% hydrochloric acid, as compared with pure reduced iron. The rate of solution was determined by measuring the rate of evolution of hydrogen from a polished surface of the metal in contact with the acid. Mere contact with copper wire had a marked retarding effect on the rate of solution of pure iron, whilst platinum and silver were without effect. Experiments with 57% sulphuric acid gave erratic results. It is emphasised that no conclusions regarding the behaviour of these alloys with dilute acids can be drawn from these experiments with strong acids. (*Cf.* J.C.S., May.) —E. H. R.

Nickel steel; Static and dynamic tension tests on ——. J. J. Thomas and J. H. Nead. Trans. Amer. Inst. Min. and Met. Eng., Feb., 1921. 13 pages.

An attempt to determine the relation between static and dynamic tensile tests as measured by the work required to break test specimens slowly in a tensile testing machine, and rapidly, by means of a falling weight. Using a nickel steel, tempered to varying degrees of hardness, the results show that for hard steel the total work of rupture is very low under either a slowly or rapidly applied load. As ductility increases the work of rupture increases, and ductility, as measured by elongation and reduction of area in the ordinary tensile test, is important a an indication of strength as measured by work units. Experiments indicate that steel is in its best condition when quenched and drawn at a tempera ture slightly lower than its critical point.—C. A. K

Ferromanganese; Manufacture of —— *in th electric furnace.* R. M. Keeney and J. Lonergan Trans. Amer. Inst. Min. and Met. Eng., Feb 1921. 36 pages.

Comparing blast furnace and electric furnace pr duction of ferromanganese, the same recovery (72 of manganese was made in the electric furna smelting ore containing 34·8% Mn as in the bla furnace smelting 40% ore. The slag and sta losses were practically the same in each case. (the same grade of ore the electric furnace wou show at least 5% greater recovery than the bla furnace, and at the present price of coke, fuel a power costs balance. In smelting oxide ore bett operating results were obtained when any necessa iron was added in the form of manganiferous o rather than in the form of steel turnings. Amo the general operating difficulties encountered wi the electric furnace, formation of carbide was t most serious. This tendency was modified by t use of lignite as a reducing agent in preference anthracite or bituminous coal and also by n attempting to produce a slag containing less th 12% Mn. Intermittent charging gave bet results than continuous working in so far as outp power, and labour costs were concerned. Magnes is preferred as a material for furnace bottor though carbon and firebrick bottoms are in use. a 1100-k.w. furnace smelting 34·8% manganese and producing ferromanganese containing 73 Mn, the power consumption was 4457 k.w.-hou and the electrode consumption 125 lb. per short t —C. A. K

Gold; Extraction of —— *from its ores.* R. Paul Chem.-Zeit., 1921, 45, 285—287.

For regulating the flow of pulp to the amalgamat plates so as to ensure removal of heavy antim sulphide, whilst at the same time preserving ficient time of contact for amalgamation, a devic installed between the tube-mills and the plates. consists of a gutter bent twice at right angles provided with cross-baffles which retard the and cause deposition of coarse particles of g Near the plates the gutter is expanded to t width, and at this point an automatic regula is inserted, which interrupts the flow of pulp allow of amalgamation and then again accelera it to admit of the antimony sulphide being car away. Experiments have shown that ball mills not very efficient in separating gold from its o gold apparently free was found to be enclosed i thin layer of quartz and contained only 12·5% actual free metal capable of amalgamation; stitution of roller mills or tumbler mills may advantageous. To reduce loss of amalgam f the plates, a "catcher" consisting of a cast- cup with rim and overflow is placed below th The slime enters by means of a central tube

any amalgam gradually separates on the bottom of the cup. It is periodically transferred to a cast-steel drum containing a few steel balls, in which it is treated with fresh mercury, and then washed with water, and pressed to recover solid amalgam.
—W. J. W.

Platinum and gold; Microscopical detection of —— in the Siegerland "grauwacken." H. Schneiderhöhn. Metall u. Erz, 1920, 17, 511—514.

The rock is a medium-grained grey sandstone with a sericite binding material. It contains very thin dark streaks running parallel to each other, which, under the microscope, are seen to be enrichment zones of heavy minerals, mostly zircon and rutile. Sections of the mineral were cut and carefully polished by means of magnesia on a piece of flannel. On viewing the prepared specimens under the microscope in transmitted light a few bright yellow particles of metallic appearance could be seen which readily became grey and rough on adding a small drop of mercury to the specimen, thus indicating gold. Platinum could not be detected with certainty in this manner. 150 g. of the finely powdered rock was then treated with hydrofluoric and sulphuric acids for several days on the water-bath. The residue, under the microscope, showed bluish-white and yellow grains of platinum and gold, which were confirmed microchemically as potassium, rubidium, and thallium chlorplatinates and as thallous chloroaurate respectively.—A. R. P.

inc; Value of —— in the ore and the economic basis of its recovery. Paul. Metall u. Erz, 1920, 17, 439—449, 475—578, 514—519; 1921, 18, 59—66, 126—135.

he customary formula on which zinc ores are sold s V=P (t−8)−K, where V is the value of 1000 kg. f the ore, t is the zinc content %, P is the market rice of one unit (=10 kg.) of spelter, and K is he returning charge. The latter varies with he nature of the ore, and the author shows that should be higher for roasted ores than for aw blende in a proportion which is greater the igher the sulphur content and the price of pelter and the lower the zinc content of the riginal ore. With equal returning charge the alue of zinc in an ore per unit increases rapidly ith the zinc content; on the other hand low-rade ores may become of negative value when e price of zinc is low (*cf.* J., 1919, 18 A). The bove formula is examined from every point of view nd reasons are advanced to show that it does not irly represent the value of an ore. Thus the turning charge is the same for rich and poorer es, while the proportion of "free" units is relavely smaller with rich ores, and hence there is not ch a great proportionate margin for losses, therere the richer ores are dearer than they should be relation to the poorer. Again the cost of smeltg depends not on the amount of ore smelted, but the capacity of the furnace, and this varies cording to the apparent specific gravity of the arge. No account of this is taken in the formula, r of the value of the sulphur. The author therete suggests two new formulæ, one for roasted and for unroasted ores. In the case of sulphide s a 1% loss of zinc on roasting is assumed and ss in weight of (t_s-15)%, where t_s is the sulphur tent of the ore. It is also assumed that 95% of sulphur removed is recovered as sulphuric acid 60° B. (sp. gr. 1·71). If the cost of roasting is proximately 15 M. per ton of roasted ore, while t of making a ton of sulphuric acid is 8·5 M. its selling price is 25 M., then the value of a t (10 kg.) of zinc in the ore in M. is given by equation

$$V=0{\cdot}08415(P-E)-(115-t_s)K/100\delta.t_z+(0{\cdot}56878283t_s-24{\cdot}275)/t_z,$$

where P is the market price of 100 kg. of spelter, E is the profit on every 100 kg. of zinc recovered, K is the cost of 1 cub. m. of retort room, δ is the apparent sp. gr. of the ore, t_z is the zinc and t_s the sulphur content of the ore. With oxidised ores this simplifies to $0{\cdot}085(P-E)-K/\delta t_z$.—A. R. P.

Zinc; Sources of loss in the distillation of ——, and the mechanism of the volatilisation of the metal. O. Mühlhaeuser. Metall u. Erz, 1921, 18, 1—22, 45—51.

Beginning with a new retort, the author carried out a series of zinc distillations from roasted blende and anthracite in a small experimental furnace and tables are given showing the yield of metal and of by-products together with the losses. The loss of zinc in the low-grade residues was about 3% and remained practically constant throughout the tests. The loss due to escape of zinc vapours from the receiver was comparatively high with the first charges, but eventually, after 10—12 distillations had been carried out in the same retort, sank to an approximately constant figure of 1·2—1·6%. The proportion of zinc that escaped through the pores and minute cracks in the retort was about 2—3% with a new retort, but after several distillations the loss from this source fell to 0·8—1·2%. The most serious loss of zinc with new retorts appears to be that due to combination of the zinc oxide with the material of the retort with the formation of zinc spinel. This loss may be as high as 25% or more of the total zinc in the charge, but on continued use of the retort it falls to an average of a little over 1%. The total average loss for the first eight charges was about 19% and for the next ten 7%. The mechanism of the volatilisation of zinc is discussed and the need of research to reduce the losses is emphasised.—A. R. P.

Brasses; Tensile strength of various —— at high temperatures. F. Doerinckel and J. Trockels. Int. Zeits. Metallogr., 1920, 12, 340—358. Chem. Zentr., 1921, 92, II., 553.

A number of tests were carried out on brass cylinders, 18 mm. diam. and 36 mm. high, in a 40-ton testing machine at various temperatures up to 800° C. The test pieces were heated by enclosing them in a resistance tube-furnace and the temperatures were measured by means of a thermocouple and, after testing, calorimetrically. The tensile strength in general falls with rising temperature, and at 800° C. has a value only ½ that obtained at 500° C.; only with a 58% Cu brass is a minimum value reached at 700° C. The maximum value of both the hardness and tensile strengths of the copper-zinc series is obtained in the region corresponding to the α-mixed crystal phase, *i.e.* with alloys containing about 85% Cu. Alloys containing 67—72% Cu exhibit irregularities, which seems to show that the α-brasses require further investigation.—A. R. P.

Tin ore; Electric smelting of ——. H. Krebs. Metall u. Erz, 1921, 18, 77—78.

Tin ores become conductors of electricity at moderate temperatures, so that by using large pieces of ore as a resistance, sufficient heat can be developed to melt it and reduce it to metal on the addition of coal. It is not generally necessary to add any slagging material, as the ore usually is self-fluxing, nor is it necessary to protect the tin oxide from going into the slag. It is preferable to carry out the process in a trough furnace with a low charging shaft and two or more electrodes dipping into the bath. Ore and coal are charged in as required and the metal is tapped from the bottom until the hearth is nearly full of slag, which should be rich in tin. This is cleaned by adding a charge of coal only to separate its tin contents as

metal. In this way very pure metal may be obtained and the tin content of the slag reduced to as low as 0·3%, while the losses by volatilisation are much less than by the reverberatory or shaft furnace process.—A. R. P.

Copper-antimony system; The compounds Cu_5Sb_2, Cu_2Sb, and Cu_3Sb in the ——. H. Reimann. Z. Metallk., 1920, **12**, 321—331. Chem. Zentr., 1921, **92**, I., 484.

THE work of Carpenter (J., 1913, 979) brought about changes in the copper-antimony equilibrium diagram, but some points remained to be cleared up. The present investigation has been confined to alloys containing 25 to 33 atoms % Sb. The maximum of the melting-point curve lies not at 25 atoms % Sb, corresponding with a compound Cu_3Sb, but at 29 atoms % Sb or the compound Cu_5Sb_2 (m.p. 682° C.). This compound forms mixed crystals with copper or antimony over the range from 18 to 33 atoms % Sb; the saturated mixed crystals with 33 atoms % Sb undergo decomposition and form a eutectoid at 27 atoms % Sb (430° C.).—E. H. R.

Bearing metals and their technological evaluation. J. Czochralski. Int. Zeits. Metallogr., 1920, **12**, 371—393. Chem. Zentr., 1921, **92**, II., 552—553.

THE mechanical properties and uses of various bearing metals are discussed and compared, together with the technique of casting and testing the finished alloys. Copper-tin bearing metals with about 10% Sn consist of a single constituent, α-CuSn, which contains generally all the other components of the alloy in solid solution. As the suitability of an alloy for use as a bearing metal depends on its heterogeneous structure, copper-tin alloys that have been rendered homogeneous are not of any use as bearing metals. The utility of a copper alloy as bearing metal depends on the gradual wearing away of the unevenness of structure, whereas that of a tin bearing metal (white metal) depends on the flexibility of the ground mass. Copper alloys are more suitable for bearings that have to withstand a considerable pressure, while lead alloys are preferable if the pressure on the bearings is small. Tin alloys occupy an intermediate position, but they are better than those containing calcium or barium instead of tin. These latter are difficult to prepare on account of the readiness with which they oxidise. It is recommended to cast these alloys at a temperature of 200° C.—A. R. P.

Heusler's alloys. II. Magnetic measurements of Heusler's aluminium-manganese bronzes of high iron content. O. von Auwers. Ann. Physik, 1920, **63**, 867—899. Chem. Zentr., 1921, **92**, I., 485. (*Cf.* J., 1920, 27 A.)

ADDITION of iron, from 13·5 to 18%, to aluminium-manganese-bronzes does not appreciably affect their magnetic behaviour. It is possible that the manganese content is more important than the iron content. At low temperatures the magnetisability of the Fe-Al-Mn-bronzes generally increases. With a bronze containing 9·2% Al, 17·8% Mn, 13·5% Fe, and 59·6% Cu, the opposite effect was observed at −190° C., but not at −78° C.—E. H. R.

Dental amalgam; Volume changes in a —— *as a result of a transformation at 70° C.* A. W. Gray. Phys. Rev., 1920, **15**, 524—525. Chem. Zentr., 1921, **92**, II., 552.

ON heating dental amalgams that had been allowed to harden to their transformation points, those containing several per cent. of zinc rapidly formed crystals, while those free from zinc showed no change. Freshly prepared amalgams, on the other hand, showed the crystal formation in all cases. The crystals consisted of hexagonal plates belonging to the hexagonal or orthorhombic system. The temperature-volume curve for the zinc-free alloys rises in a straight line to a maximum at the transformation point, rapidly falls to a minimum, and then rises sharply for a short distance, after which a further fall takes place. On re-heating a similar curve is obtained, except that the change point is not so strongly marked, especially with alloys with a low silver and high copper content. Amalgams that contain zinc give a curved line up to the change point, after which the line rises rapidly. This rapid expansion ceases after several hours or if the temperature is kept constant or allowed to fall.
—A. R. P.

Aluminium-mercury alloys; Electromotive behaviour of ——. R. Kremann and R. Müller. Z. Metallk., 1920, **12**, 289—303. Chem. Zentr., 1921, **92**, I., 482—483.

ALUMINIUM amalgam was best prepared using a solution of mercuric chloride. The E.M.F. of cells of the type, $Hg/0{\cdot}1N\ KAl(SO_4)_2/Al_x\ Hg_y$, was measured. The potential of mercury against the normal calomel electrode was +0·2, that of aluminium −0·82 (constant values could not be obtained on account of the formation of surface layers), and that of the amalgam −1·314 to −1·352 volt, almost independent of the composition. The results indicate the formation of a compound of mercury and aluminium, the composition of which could not be determined. Similarly, in combinations of the type $Hg/0{\cdot}1N$ NaI in pyridine $/Al_x Hg_y$ the potential of the amalgam is, independent of its composition, about 0·25 voltless "noble" than that of aluminium.—E. H. R.

Magnesium-mercury alloys; Electromotive behaviour of ——. R. Kremann and R. Müller. Z. Metallk., 1920, **12**, 303—312. Chem. Zentr. 1921, **92**, I., 483.

THE potential of pure magnesium, as determined from the combination, $Pb/0{\cdot}5$ to $1{\cdot}0N\ MgSO_4/Mg$ is −1·48 to −1·68 volts. Slight amalgamation brings the value to −1·71 to −1·79 volts. Magnesium and mercury readily combine at the boiling point of the latter. Magnesium amalgams when exposed to the air quickly become covered with brownish-black skin of MgO, $Mg(OH)_2$, and $MgCO_3$ coloured with finely divided mercury; oxidation also occurs in a desiccator. Traces of magnesium bring the potential of mercury to a value 0·3 volt less "noble" than that of magnesium; this value persists up to 85 atoms % Mg, then rises a further 0·17 volt to a maximum at 91 atoms % Mg, afterwards falling again. The maximum may be due to a compound, $Mg_{10}Hg$, less "noble" than either component, which is solid at ordinary temperatures and forms mixed crystals with magnesium and probably with mercury.—E. H. R.

Alloys of magnesium with lead and cadmium; Electromotive behaviour of ——. R. Kremann and J. Gmachl-Pammer. Z. Metallk., 1920, **12**, 403—406. Chem. Zentr., 1921, **92**, I., 484.

EXPERIMENTS on the E.M.F. of the combination $Pb/0{\cdot}5$ molar $MgSO_4/Pb_xMg_{1-x}$ indicate the existence of a compound $PbMg_2$. Alloys with 0—33 atoms % Pb have practically the potential of pure magnesium, those with 33 atoms % Pb up to nearly pure lead have a potential only 0·14 volt "nobler." The heat of formation of the compound is therefore relatively small. The compound rapidly decomposes in air to a black metallic powder consisting of black magnesium suboxide, lead, and, probably lead suboxide. Similar experiments with magnesium-cadmium alloys agree with the equilibrium diagram for these alloys, indicating the existence of a compound MgCd 0·10 volt "nobler" than

magnesium, 0·86 volt less "noble" than cadmium. This compound also disintegrates quickly in air. —E. H. R.

Metallurgical furnaces; Basis of the heat losses of ——. P. Rosin. Metall u. Erz, 1920, 17, 463—475; 1921, 18, 37—45, 78—88, 99—104.

A THEORETICAL and mathematical investigation into the factors governing the loss of heat by radiation and convection from furnaces. The four factors governing the magnitude of the losses are the shape of the furnace, the nature of the materials used in its construction, the difference in temperature between the inside and outside surface of the walls, and the time consumed by a unit charge in passing through the furnace. For every furnace on steady work there is a lower limit to the amount of heat lost by conduction, and this amount cannot be reduced by thickening the walls. If the charge completely fills the furnace, less heat proportionately is lost than if it only partly does so, while a large furnace loses relatively less heat than a smaller one. The ideal form for a cylindrical furnace is one in which the height is equal to the diameter; for a rectangular furnace, a cube; and for a prismatic furnace, one having its height equal to the cross-section. A method of determining the heat conductivity of furnace bricks is described, and a table is given showing the results obtained at various temperatures for the principal varieties of firebrick.—A. R. P.

PATENTS.

Steel; High-speed ——. C. M. Johnson. U.S.P. 1,370,020, 1.3.21. Appl., 12.12.19.

A STEEL containing C 0·20—0·75%, Si 0·35—0·80%, Mn 0·35—0·55%, W 12—18%, Cr 3—5%, V 1·1—1·5%, Mo 0·25—1·0%.—J. W. D.

Iron; Method of making wrought ——. J. Aston, Assr. to A. M. Byers Co. U.S.P. 1,370,622, 8.3.21. Appl., 14.11.19. Renewed 30.6.20.

MOLTEN metal from a steel-making process is granulated (*e.g.*, by dropping vertically) and caused to fall into a bath of iron silicate slag in a container of such shape that a coherent ball or sponge of mixed metal and slag is formed below the level of the slag bath.—C. A. K.

Iron and steel: Method of and apparatus for the production of ——. E. Riveroll, Assr. to California Electric Steel Co. U.S.P. 1,370,915, 8.3.21. Appl., 12.5.19.

IRON ORE is heated by means of reducing and carburising gas under such conditions as to temperature and time that part of the ore is reduced to carburised sponge iron and the other part is unchanged; the reaction is completed by heating the mixture thus formed to complete the reduction and melt the reduced iron.—B. V. S.

Ferro-chromium; Producing low-carbon ——. F. Krupp A.-G. E.P. 145,709, 26.6.20. Conv., 27.7.16.

HIGH-CARBON ferro-chromium is introduced in molten form into a converter and blown for a longer or shorter period according to the carbon content desired.—J. W. D.

Ferro-chrome alloys; Production of ——. W. B. Ballantine. E.P. 159,568, 24.11 and 18.12.19, and 13.1.20.

A CHROMIUM compound, *e.g.*, chromite, is reduced by means of a cheap reducing agent, such as calcium carbide, and the resulting crude molten alloy submitted to the action of an oxidising blast in a Bessemer or like converter. The chromium content of the refined alloy is adjusted, before or after tipping from the converter, by means of a thermo-reducing mixture containing a chromium compound.—J. W. D.

Electrodes; Arc-welding ——. Wilson Welder and Metals Co., Inc., Assees. of J. Churchward. E.P. 148,265, 16.12.19. Conv., 21.7.19.

A FILM of rust is formed on the cleaned electrode rod by immersion in acidulated water, and the rod is then dipped in milk of lime and dried, the dipping process being repeated until a deposit of sufficient thickness is obtained. After baking at 300° F. (150° C.) the rod may be drawn through a wire-drawing die to the required size. The lime coating becomes incorporated with the porous oxidised surface of the metal, and is not detached by subsequent abrasion or bending of the electrode. —C. A. K.

Electrodes for electric arc welding. H. Ogden, and The British Arc Welding Co., Ltd. E.P. 159,742, 24.1.20.

A BARE electrode is coated uniformly with a flux paste containing not more than 5% of glue or casein by inserting it through an adjustable hole in the end of a rectangular vessel containing the flux mixture. The paste is of such consistency as not to extrude through the hole in the containing vessel.—C. A. K.

Furnace for subjecting ores or other materials to the action of gases, or the like. British Oxygen Co., Ltd., S. W. Bray, and I. H. Balfour. E.P. 159,530, 9.10.19.

AN inclined retort extends through a furnace provided with gas burners or other means for heating the retort. The material to be treated is fed into the upper end of the retort in definite quantities from a hopper by means of a sliding or plunger valve. A similar device allows the discharge of the heated material into a closed receiver. Scoops fixed to a rotating longitudinal shaft agitate the material in the retort, and the required atmosphere is obtained by passing a suitable gas into the lower end of the retort and providing an outlet at the upper end.—C. A. K.

Copper alloys. Sir W. G. Armstrong, Whitworth, and Co., Ltd., C. J. G. MacGuckin, and O. Smalley. E.P. 159,537, 24.10.19.

ALLOYS containing Cu 80—91%, Al 7—10%, Mn 1—6%, Fe 1—4%, retain their strength up to 450° C., and are especially suitable for the manufacture of turbine blades.—J. W. D.

Tin; Purification of —— *or production of tin salts from crude tin.* J. J. Collins. E.P. 159,659, 10.12.19.

IMPURE or crude tin, in a more or less finely divided state, is subjected to the action of stannic chloride, whereby the tin is dissolved and stannous chloride produced, and chlorine gas is injected into the latter so that it continuously absorbs chlorine and gives it up to the metallic tin for the production of further quantities of stannous chloride. —J. W. D.

Solder. A. H. Phillips and C. G. Arnold. E.P. 159,797, 13.7.20.

A SOLDER (m.p. 257° C.), especially suitable for use with cast iron, has the composition 2·2% Co, 10·0% Cu, 0·6% Ag, 0·6% Sb, 86·6% Sn. The cobalt is melted first, and the other metals are added in the above order.—C. A. K.

Tungsten [-silicon] alloy. The British Thomson-Houston Co., Ltd. From General Electric Co. E.P. 160,373, 17.4.20.

TUNGSTIC acid, containing a small quantity of silicic acid, is mixed with sufficient magnesium to

reduce the silica, and the mixture is heated in hydrogen. Alternatively the mixture of tungstic acid and silica may be reduced in hydrogen, and the resulting X-metal (*cf.* E.P. 155,851; J., 1921, 265 A) mixed with the requisite quantity of magnesium powder to reduce the silica and again heated. In either case the magnesium oxide is extracted from the metal powder by means of hydrochloric acid. The resulting metal, containing 1—3% Si, when worked into wire gives a filament that does not sag and shows great resistance to shock.—A. R. P.

Tungsten; Extraction and recovery of ——. A. G. de Golyer and A. E. Lund. U.S.P. 1,335,277, 30.3.20. Appl., 11.5.16.

The powdered ore is heated and agitated with an alkali hydroxide or carbonate solution, and a salt of calcium, barium, mercury, lead, or silver is added to the filtered alkali tungstate solution to precipitate an insoluble tungstate.

Aluminium; Process for making powdered or granulated ——. L. B. Tebbetts. U.S.P. 1,327,743, 13.1.20. Appl., 4.12.17.

Aluminium is heated above its melting point and then agitated while it cools. The metal is very brittle at temperatures just below the m.p., and can be readily disintegrated.

Manganese-silver ores; Treating ——. L. W. Austin. U.S.P. 1,327,974, 13.1.20. Appl., 14.4.19.

Refractory manganese-silver ores are rendered much more amenable to cyanide treatment if they are mixed with pyrites and sulphuric acid, and the product washed with water.

Ore concentration. B. H. Dosenbach, Assr. to E. M. Dosenbach. U.S.P. 1,350,364, 24.8.20. Appl., 16.11.17.

A modification of the flotation process in which the ore pulp is treated with a gaseous modifying agent such as coal gas or other gas obtained by distillation which has been previously treated with water to remove soluble matter and which effects flotation of certain constituents of the ore.—A. R. P.

Flotation of minerals. (A) C. L. Perkins, (B) (C) R. E. Sayre, Assrs. to Metals Recovery Co. U.S.P. (A) 1,370,357, (B) 1,370,366, and (C) 1,370,367, 1.3.21. Appl., (A) 13.7.20, (B) (C) 2.7.20.

After an addition to the mineral pulp of a small quantity of (A) terpene hydrate, (B) a dihydric alcohol, or (C) a thio-aldehyde compound, a flotation operation is carried out.—C. A. K.

Flotation of minerals. R. E. Sayre, Assr. to Metals Recovery Co. U.S.P. 1,370,843, 8.3.21. Appl., 2.7.20.

A small quantity of a ketone condensation product is added to mineral pulp to assist in the mineral concentration during a subsequent flotation operation.—C. A. K.

Precious metals; Process for extracting ——. C. P. Priest. U.S.P. 1,352,832, 14.9.20. Appl., 21.8.19.

Ores or sands containing precious metals are ground in a solution of sodium chloride, then mixed with a solution of a mercury compound (*e.g.*, mercuric chloride), and the resulting slime electrolysed to produce hydrogen and effect amalgamation of the metal.

Alloy. T. Kosugi. U.S.P. 1,369,818, 1.3.21. Appl., 30.6.20.

An alloy containing Cu 75—90%, Al 7—12%, Ni 2—7%, and Fe 1—6%.—J. W. D.

[Alloy for] production of gears. R. D. Babson, Assr. to Baush Machine Tool Co. U.S.P. 1,371,214, 15.3.21. Appl., 3.3.20.

An alloy containing aluminium about 94%, magnesium about 0·5%, manganese, and copper is subjected to excessive working, then heated to about 500°—525° C., and quenched.—W. J. W.

Metallic oxides; Reduction of ——. C. M. Johnson. U.S.P. 1,370,021, 1.3.21. Appl., 9.6.20.

The reduction of the oxide is effected by smelting in the presence of both ferrosilicon and ferrochromium.—J. W. D.

Leach liquor; Treatment of ——. C. R. Hayward, H. M. Schleicher, and F. O. Stillman, Assrs. to Moa Iron and Development Corp. U.S.P. 1,370,646, 8.3.21. Appl., 8.12.19.

A solution containing the sulphates of metals of different valencies is first converted into a chloride solution, and the metals are then selectively precipitated by suitable reagents.—A. R. P.

Metal surfaces; Ornamenting and protecting ——. O. Hommel. U.S.P. 1,370,967, 8.3.21. Appl., 16.5.18. Renewed 5.8.20.

A solution of a metallic salt is applied to the surface of a metallic article containing aluminium so as to produce an even coating of the salt thereon. The article is then heated to such a temperature that the aluminium reduces the metallic salt with the formation of a coating of the metal which adheres to the underlying metal.—A. R. P.

Nickel-plating. T. A. Edison. U.S.P. 1,371,414, 15.3.21. Appl., 17.6.19.

A nickel sulphate solution is used as an electroplating bath, and portions of it are continuously withdrawn, treated with nickel hydroxide, and returned to the bath.—A. R. P.

Lead-coating process. R. J. Shoemaker, Assr. to Leadizing Co. U.S.P. 1,371,445, 15.3.21. Appl., 11.12.20.

A permanently adherent coating of lead is formed on iron or steel articles by immersing the metal in a solution containing not less than 35% of lead acetate.—C. A. K.

Briquetting [metal fragments]. O. C. Duryea and M. C. White, Assrs. to American Briquet Machine Co. U.S.P. 1,371,671, 15.3.21. Appl., 14.2.17.

Small metallic fragments are pressed into an approximately solid mass by applying a comparatively mild pressure. A high pressure is then exerted by explosive force, whereby the metal becomes practically welded together.—C. A. K.

Substances sensitive to oxidation; Process for heating or firing —— e.g., iron, steel, porcelain, and the like. H. Koppers. G.P. 331,924, 14.5.18.

The articles are heated by means of gas, the quantities of gas and air used being so regulated that in the immediate neighbourhood of the articles a reducing atmosphere free from carbon dioxide is maintained. Iron articles are given a protective coat of clay and graphite or other carbonaceous material that will not carburise the iron, while porcelain articles that are burnt in saggers are covered with a quantity of specially-prepared wood charcoal. This method prevents the scaling of iron or the discoloration of porcelain during heating.—A. R. P.

Iron and phosphorus; Recovery of —— from slags from iron-smelting. Eisen- und Stahlwerk Hoesch A.-G. G.P. 332,118, 24.6.19.

The molten slag is treated with chlorine or with

chlorine and carbon monoxide together or successively, and the sublimed iron chlorides are collected in a cooled receiver. The residue may be used as a fertiliser, or worked up for the recovery of its phosphorus content by mixing it with carbon and heating the mixture to 700°—800° C. while passing chlorine or carbon monoxide and chlorine through it, whereby chlorides of phosphorus are evolved and condensed in suitable receivers. The original slag may, alternatively, be mixed with carbon and treated with chlorine when, according to the conditions under which the treatment is carried out, iron or phosphorus chlorides are evolved.—A. R. P.

Aluminium; Process for deoxidising and refining ——. Process for deoxidising and refining copper. A. Strasser. E.P. 141,324 and 142,441, 24.12.19. Conv., 9.4 and 26.4.19.

PATENTS.

Electrolysers. R. Pechkranz. E.P. 146,184, 25.6.20. Conv., 27.6.19.

In an electrolyser in which the surface of the electrolyte is open to the atmosphere, parasitic electrolysis on the edges of the electrodes is prevented by employing vertical electrodes alternating with vertical diaphragms and united integrally therewith. The electrodes are mounted in a grooved frame, but do not extend to the lateral and lower outer edges of the frames, which are immersed in the electrolyte. The block of electrodes carried by the frames is surmounted by a multicellular cover made of insulating material and serving as a separating chamber for emulsions and as a collecting chamber for the gases evolved.—J. S. G. T.

Electrolytic cell. L. W. Chubb, Assr. to Westinghouse Electric and Manuf. Co. U.S.P. 1,348,207, 3.8.20. Appl., 4.4.17.

The cell comprises a container of "film-forming material" (*e.g.*, aluminium, tantalum, magnesium) and a number of electrodes of the same material arranged in an electrolyte, alternate electrodes being connected with terminals of opposite polarity. Each outer electrode has a superficial area about one-half that of an intermediate electrode.

Acid-proof and insulating materials. F. J. Harden. E.P. 159,956, 4.12.19.

An acid-resisting, insulating material is made by melting together about 10 pts. by weight of asphaltum and 5 pts. of coal tar pitch, grinding the cold mixture and mixing therewith 2 pts. of flowers of sulphur, 4 pts. of pumice or other inert powder, 4 pts. of silicate of iron or other metal, 3 pts. of lampblack or finely divided carbon, and 1·5 pts. of paraffin wax. The whole is damped with petroleum and heated for about ½ hr. to a temperature not exceeding the melting point of sulphur. The material may be employed in the manufacture of boxes or containers for electric batteries.
—J. S. G. T.

Fireproof insulating masses from silicates and combustible substances; Preparation of ——. L. Kern. G.P. 331,026, 30.10.19.

MINERAL acids or their salts, excepting aluminium salts or alums, are added before or after mixing the combustible substance with silicates, and the mixture is thereafter formed, dried, and burnt in known manner. The mineral acids or their salts are dissolved in water and added, in quantities of 0·1—0·5%, to the coal or to the mixture of coal, carbonaceous matter, and silicates.—A. de W.

Electric furnaces. E. C. R. Marks. From Scovill Manufacturing Co. E.P. 160,082, 15.3.20.

In a furnace working on polyphase current delivered to the charge by electrodes disposed so as to produce an inner rotating magnetic field, and a weaker outer magnetic field between the electrodes and the furnace wall, an additional magnetic field rotating in planes parallel to the surface of the molten charge is produced by connecting the electrode leads with bus-bars carried down the sides of the furnace and supported either inside or outside the furnace casing. The effect of this field is increased by employing a distributed current carrier comprising a number of bus-bars, which may extend underneath the charge. The additional field, according to its direction, co-operates with either the inner or outer fields, whereby the efficiency of heating and mixing of the charge is increased.—J. S. G. T.

Electric furnace for calcining magnesia and for similar purposes. F. S. Newall. E.P. 160,231, 9.12.19.

WITHIN a vertical cylindrical retort is a central stationary cylindrical resistance element, forming an annular chamber through which the material to be calcined travels in direct contact with the resistance element. The retort is supported by a carrier mounted on rollers, and means are provided for imparting a rotary or vibrating motion to it. An internal screw or the like within the retort retards the fall of the material to be calcined and ensures thorough agitation.—J. S. G. T.

Electric furnaces; Electric system for ——. H. A. Greaves and H. Etchells. U.S.P. 1,370,016, 1.3.21. Appl., 12.9.18.

In an electric furnace with three, or a multiple of three, upper electrodes, and a hearth forming an electric resistance, combined with the "inverted star" system of three-phase transformer grouping, the insertion of a fourth transformer between the common terminal junction of the secondary windings of the original three transformers and the hearth electrode connexion, provides a means of varying the amount of electrical energy used for heating the hearth.—W. J. W.

Electric furnace. W. R. Clark, Assr. to Bridgeport Brass Co. U.S.P. 1,370,632, 8.3.21. Appl., 8.9.19.

A COMBUSTION chamber is arranged in the upper part of an electric furnace of the induction type provided with a secondary circuit below the upper surface of the charge, in order to prevent chilling or incrustation of that surface.—J. S. G. T.

Storage batteries; Filling for [dry] ——. C. A. Allison. From S. Narabayashi. E.P. 160,317, 8.1.20.

A FILLING for dry storage batteries consists of 70% of pumice-stone powder freed from metallic com-

pounds and 30% of shredded asbestos or nitrated cotton. The filling is packed between the battery plates and soaked with a solution of sulphuric acid.—J. S. G. T.

Storage battery; Electric ——. C. J. V. Féry. U.S.P. 1,371,746, 15.3.21. Appl., 24.3.19.

A LEAD negative electrode is arranged horizontally at the bottom of a lead jar containing a "fixed" solution of sulphuric acid, and a positive electrode of lead peroxide is arranged vertically above the negative electrode. The horizontal cross-sectional area of the positive electrode is such that, during the charging operation, an upward movement of SO_4 ions occurs throughout the height of the jar, whereby the concentration of the acid is maintained constant, and the gases evolved at the negative electrode may escape without reacting with the positive electrode.—J. S. G. T.

Storage-battery separator. G. Steerup, Assr. to U.S. Light and Heat Corp. U.S.P. 1,370,064, 1.3.21. Appl., 7.6.19.

WOOD is treated so as to increase its porosity, and is then impregnated with ammonia gas. The free ammonia is volatilised and the wood treated with steam at such a temperature and for such a time as would injure the cellular structure of untreated wood.—J. S. G. T.

Pasting; Two-solution method of ——. [*Manufacture of electrolyte for dry cells.*] W. B. Schulte, Assr. to Burgess Battery Co. U.S.P. 1,370,056, 1.3.21. Appl., 10.6.20.

A PASTE for use as electrolyte in a dry cell is prepared by adding a solution of zinc chloride and ammonium chloride in water to a suspension of starch in a solution of zinc and ammonium chlorides, whereby gelatinisation of the electrolyte is effected.—J. S. G. T.

Electrolytic gas-generator. I. H. Levin, Assr. to Electrolytic Oxy-Hydrogen Laboratories, Inc. U.S.P. 1,372,442, 22.3.21. Appl., 22.5.17.
